Whereas, the legal committee of the National Electric Light Association has drafted bills looking to the establishing of a court of patent appeals, to the increase in the salary of the commissioner of patents and to other amendments in the patent law, as set forth in the copies of the bills hereto attached, and,

Whereas, these measures have received the approval of the National Electric Light Association and appear to us to be wise and deserving of support, now, therefore, be it

Resolved, that the secretary of the Chicago Electric Club be, and hereby is, instructed to convey to Hon. Edward Lane, Member of the House of Representatives from Illinois, and a member of the House Committee on Patents, the sentiment of the club approving these measures, and to urge a favorable action thereon by the Committee on Patents.

Mr. Durant, General Manager of the Bell Telephone Co., of Missouri, has finally succeeded in closing up what was at one time a vigorous opposition exchange in St. Louis. Inferior instruments and service had reduced the number of subscribers to about seventy. These subscribers recently turned their instruments over to the solicitors of the American Bell Telephone Co., by and with the advice and consent of the Pan Electric Telephone Co., and thus rendered it unnecessary to bring further action against them. Mr. Durant spent a day in Chicage this month.

The Cushman Telephone Co. has secured a franchise in Chicago, while the Chicago Telephone Co. has failed even to get permission to move the wires of such of its subscribers as change their residences or offices on the 1st of May. The franchise of the Cushman company, which has not yet received the Mayor's approval, limits the price to be charged for telephone service to $95 for the first year, $85 for the second year and $75 for three year contracts.

The Chicago telephone building is now about ready for occupancy, and on the 1st of May the executive offices of the Chicago and Central Union Telephone companies will be moved to that building.

Mr. Wilson claims confidently to have the best equipped central office in the world. It has numerous original features. The method of wiring and the distributing boards are particularly novel and interesting features.

One of the largest isolated electric light plants in the world will be that for lighting the new auditorium building. A part of this building is being hastened to completion now, in anticipation of the republican national convention. In the auditorium part of the structure there will be 5,000 incandescent lights, and in the offices and hotel which will occupy the rest of the block, there will be 3,600 lights.

The Postal Telegraph Co. will move to their handsome offices in the Phœnix building on the 1st of May.

The Dorsett underground ordinance in Kansas City was vetoed by the Mayor, and the council has since decided not to pass the ordinance over the Mayor's veto.

The City Council of Cleveland is considering the question of putting underground all electrical wires. Profiting by the experience of other cities the ordinances which are under consideration, and one of which will probably be passed, are conservative measures which provide for the gradual removal of overhead wires to suitable conduits underground, of the companies' own selection.

The Centennial Exposition of the Ohio Valley, at Cincinnati, has made arrangements with the Western Electric Company for the use of 200 arc lights during the summer. Efforts are being made to ensure success for this exposition, and it is expected that manufacturers of electrical apparatus will take advantage of the special inducements offered and make the electrical feature of the exposition a prominent one.

Professor Gray expects soon to give an exhibition of his perfected telautograph, which is described in one of the daily papers as follows:

"The little instrument which threatens to revolutionize both the telephone and the telegraph is in its general appearance a stand or table with duplicate parts. On one of these parts are the appliances for transmitting and the other for receiving. Each is a disc covered with a specially prepared paper. The operator writes on the paper as on an ordinary sheet, and the message is reproduced on the connected instrument. If the adjustment is perfect the chirography will be reproduced in perfect fac-simile, just as a telephone transmits the voice. The power of the instrument is equal to that of the telegraph, and a longer range of connection is possible than with the telephone. An advantage of the instrument will be that it will facilitate commercial business, and letters which are now handled by mail can be sent over the wire with the convenience of telephone transmission.

"Professor Gray developed the instrument some time ago and applied for patents. His claims were passed upon some time ago, and the only protection he seeks now is that of the old countries."

On the 23d of March there was incorporated the D'Unger Long Distance Telephone Co., of Chicago, capital stock $18,000,000, to conduct a general telephone business throughout the United States. The incorporators are K. E. Keefe, T. A. Broadbent and W. I. Copeland. This company is organized to exploit the telephonic inventions of Dr. D'Unger.

The Louisiana Electric Light and Power Co., of New Orleans, claims to have the largest electric lighting plant in the world. It operates 1,500 arc lights, and has 350 miles of circuit. The Fort Wayne Jenney system is used by this company, and an 1,800 incandescent light Slattery induction dynamo has been added to the station recently.

The contract for lighting the power plant of the Chicago City Railway Co. has been awarded to the Excelsior Electric Company. The contract calls for 77 arc lights and 155 incandescent lights. This company has also secured the contract for lighting the Union Stock Yards with 50 arc lights.

Mr. C. G. Sholes has been appointed superintendent of telegraph of the Chicago, Santa Fe & California Railway, with headquarters in this city, and his position as superintendent of the Chicago & Milwaukee Telegraph Co. will be taken by Mr. F. E. Crawford.

Mr. F. B. Badt, who has been hitherto in the service of the United States Electric Lighting Co., has recently severed his connection with that company and engaged in an enterprise which takes him away from Chicago, much to the regret of his friends. Mr. Badt is the author of the Dynamo Tender's Hand-book, a practical little treatise, the scope of which is indicated by its title, and which is meeting with much success.

Mr. J. I. Sabin, of San Francisco, stopped over for a day or two on his way east this month. He reports that the telephone business on the Pacific coast is in a prosperous condition.

Mr. G. E. Sutton, an employé of the Western Electric Company, met death in a sudden and painful manner on the evening of April 9th. He stepped into the shaft of the elevator on the third floor, expecting to find the elevator there. It had been moved, and he fell a distance of forty-five feet to the bottom and was killed instantly. He was a nephew of Jas. B. Speed, of Louisville, Ky., President of the Ohio Valley Telephone Co., and was an exceptionally bright and promising young man.

The City of Dunkirk has purchased a 60 arc light plant from the Western Electric Company.

The Chicago river plant proves so satisfactory that it has been decided by the city authorities to double its capacity.

Numerous electric railroads are being projected and constructed in the west. One of the latest contracts announced is that at Davenport, Ia., taken by the Sprague Electric Railway Motor Co. Six of the eight cars with which the road is to be equipped will be running by July 1st.

CHICAGO, April 21, 1888.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall street, New York city.*

"ELECTRICAL KILLING."

[91.] Would the use of the electric current for the execution of criminals debase the science of electricity? As this is a question in morals, and not one in electricity, the electrician is no better fitted to answer it than those engaged in other honorable professions or vocations. Capital punishment is right or it is wrong. If right, it cannot lower any means that may be employed to effect it. If it be "most ignoble," then it is decidedly wrong, and not even chloroform nor the cup of hemlock should be resorted to. If wrong, it is degrading not only to all helping to bring it about—sheriff, judge, jury and law makers—but to all who even approve of it. But right or wrong, the electrician has no better ground for objecting to the use of electricity than the cutler has to the use of the guillotine, the ropemaker to the method of hanging, or the physician to the use of any poisonous drug. The profession of the physician is as exalted as that of the electrician, and the vocation of the ropemaker and of the cutler just as honorable. Does any electrician abhor the thought of the use of electricity in the guiding and exploding of torpedoes for the destruction of property and human life, and the use of the electric telegraph in aiding military operations in which human beings are slaughtered by hundreds or thousands, and, what is still more horrible, by tens of thousands made cripples for life? Or does he feel that his profession is lowered because the electric current is made to do the work heretofore performed by the horse? The object of capital punishment is the direct and indirect protection of society, and this is quite as noble as the use of electrical knowledge for the purpose of making money. Let the line be drawn between right and wrong, and then let the science of electricity, if it can, serve mankind in anything and everything that is right, for right can no more degrade than wrong can elevate.

J. E. SMITH.

New York, April 7, 1888.

ANTHONY AND BRACKET'S PHYSICS.

[92].—To the objections made by Messrs. Jackson and Osmund, to the brief notice of that portion of Professors Anthony and Bracket's *Text Book of Physics*, relating to electricity and magnetism, it is but fair to say that the only claim which they make for it,—viz., that it is "useful in conjunction with a thorough course of lectures"—was clearly allowed in the review in question.

THE REVIEWER.

LITERATURE.

REVIEWS.

Electricity and Magnetism. Being the Second Volume of Elementary Practical Physics. By Balfour Stewart and W. W. H. Gee. Macmillan & Co., London and New York, 1887.

PROBABLY most students of electricity have read with pleasure and profit the excellent standard text books of Sprague, Jenkin, Thompson, Gordon and Ayrton, not to mention others, and in each of these works have been over the same general ground of principles, laws and illustrative apparatus, in the order and style peculiar to the respective author. In each, moreover, they have doubtless found some particular subjects more exhaustively discussed than in any of the others, and some things perhaps which the others did not refer to at all. It is safe to say, however, that in no one of these books, with the exception of Ayrton's which is limited in scope, can the student turn to that part relating to any particular phenomenon and find therein such a description of its principles and laws, and methods of investigating the same, that he could, without further instruction, construct suitable apparatus to accurately measure its quantities and make the required corrections for the errors necessarily inherent in nearly all physical apparatus. So true is this that some of the practicing electricians one meets, in this country at least, familiar though they may be with the ordinary text books, are unaware that their measuring instruments are subject to any structural imperfections. Of course it is understood that such extreme refinement is not always necessary, nor even desirable in some elementary works, but a failure to even hint at the facts and an inexcusable omission of references to authoritative treatises, causes many unassisted, although careful students to be left needlessly in the dark, and even well posted practical electricians often find it a difficult matter to put their hands on the treatises of the particular authorities whom they may desire to consult.

The preceding criticism does not apply, however, to the particularly excellent text book of Professors Stewart and Gee, which is the subject of this notice. Although the field covered by this work is not by any means a narrow one, there is scarcely a subject within its range which is not thoroughly explained even to its smallest details, except where abstruse demonstrations are necessary, and then suitable references to more advanced treatises are appended. It is just such a book as advanced students and practical electricians have long wished for; a book which gives complete instruction in the actual use of precise electrical measuring instruments, the laws governing their construction, the structural imperfections to which they are subject, and the mathematical corrections which may be applied to remedy them. The galvanometer, magnetometer, electrometer, and their modifications are thus considered, and the various effective methods of standardizing them and modern tests to which they may be applied are fully treated of. The construction and use of standard batteries and voltameters, and the precautions to be observed in applying them to the determination of constants are minutely discussed. Scarcely a useful method of measuring resistance, potential, current and magnetism but what is illustrated and explained in detail.

The arrangement of the subject-matter is unique and effective. The first three chapters treating respectively of Elementary Electrostatics, Magnetism—fundamental laws and experiments, and Voltaic Electricity—fundamental laws and measurements, are introductory to the remainder of the work, so that the student finds himself well acquainted with the leading principles of the science before he gets into the less elementary portions of the work. In the fourth chapter the measurement of resistance receives unusually extended treatment. The principles and details of construction of galvanometers and rheostats and their auxiliary devices are so clearly and thoroughly explained that the careful student can have no difficulty in constructing and using practical and accurate instruments. Methods of standardizing and testing the same are given, as also most of the bridge and other resistance measurements, while throughout the necessary precautions and corrections for precise work, on the necessity for which so much stress has here been laid, are succinctly pointed out. The chapter which follows on the Tangent Galvanometer, is, undoubtedly the best that has ever been written on this subject. Those who have been compelled to search through Maxwell and works of that character for the proportions and corrections for a Helmholtz double coil galvanometer, the most reliable of all magnetic instruments for current measurements, will appreciate the variety and completeness of the data relating thereto and to kindred apparatus, which is contained therein. Formulæ for the determination of current and potential from H and the dimensions of the instrument are given in full, as well as methods of calibration by volume and weight voltameters, calorimeters and known current, with the usual attentions to details.

The determination of the magnetic elements is considered in the sixth chapter, where the Kew magnetometers and dip circle are illustrated and explained, and the determination of deflections and declinations described and applied. Here, more perhaps than anywhere else, the importance of minor corrections for imperfections in the instruments employed in physical measurements becomes apparent, and it is indeed a satisfaction to find in a convenient hand-book the frequently needed formulæ which it has heretofore been necessary to obtain in their completeness from the higher mathematical treatises. Electro-Magnetism and Electro-magnetic Induction logically forms the subject of the succeeding chapter where laws and their proofs are happily described. The condenser and electrometer and their applications to electrical measurements, are carefully treated of in the eighth and ninth chapters respectively, and the book is concluded with several valuable appendixes on the Wheatstone net, electrical force, standard cells, etc.

Throughout the work are numerous well selected practical examples, and from beginning to end it bears evidence of careful selection and masterful treatment of its subject-matter.

PERIODICALS.

The Journal of the Franklin Institute for March contains an article of much interest, by Professor Edwin J. Houston, on Paillard's Non-magnetic Compensating Balance and Hair-spring for Watches. The author describes M. Paillard's method of preventing the influence of magnetism in varying the rate of watches by the use of non-magnetic alloys—palladium being the principal ingredient—for the balance-wheel, hair-spring and escapement. Liberal quotations are given from the inventor's United States patents, including tables showing the composition of several of the alloys employed. A variety of experiments are described, as made by Professor Houston, to determine the efficacy of the protection obtained by the Paillard method. Two watches were subjected to severe tests; one had the palladium alloys in the balance-wheel and in the hair-spring, and had also a non-magnetic escapement; the other had palladium alloy in balance-wheel and hair-spring and a steel escapement. The experiments consisted substantially in exposing the watches to the action of strong magnetic fields, much stronger than they would be at all likely to encounter in use. The rates of the watches were not sensibly affected. Figures are given showing ratings before and after exposure. In conclusion Professor Houston expresses his belief, based on the results of his experiments, "that a watch containing the Paillard non-magnetic compensating balance, hair-springs, and escape-movement can safely be carried into even the most intense magnetic fields without suffering any appreciable change in its rate; and that while on the person of its wearer, it cannot possibly be brought into a magnetic field sufficiently strong to alter its rate." Of the two watches tested, the one having a steel escapement—the balance-wheel and hair-spring only being non-magnetic—stopped running when placed "in a horizontal position, face upwards, between the opposite pole-pieces of a Brush, 60-light dynamo, furnishing a current of nine and one-half amperes, and feeding 41 lamps. On taking it away from the pole-pieces it was readily started again. This experiment was repeated several times." The stoppage of the watch was due, Professor Houston thinks, "to the fork coming in contact with the steel roller-table. The watch though placed in a field that stopped it was not affected sensibly in its rate when removed therefrom."

Professor Houston's experiments indicated the further conclusion, that the palladium alloy is neither paramagnetic nor diamagnetic, but entirely neutral.

"Two palladium hair-springs of different alloys were placed in a uniform field, the direction of the lines of force in which was determined by a very thin layer of iron filings. On placing the springs in various positions in the field no change in the grouping of the lines was observable. They were neither concentrated on the palladium alloys nor repelled from them; that is to say, they were neither appreciably paramagnetic nor diamagnetic."

ELECTRICAL NEWS AND NOTES.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF APRIL 10, 1888.

The twenty-fourth meeting of the Institute was held at the house of the American Society of Civil Engineers, No. 127 East Twenty-third street, New York, April 10, 1888, the President, Mr. T. Commerford Martin, in the chair.

The President—We have before us this evening a very interesting paper, and it is somewhat remarkable that the author should have had recently another occasion of distinguishing himself in the same line in this very room. I have no doubt that he will handle his subject this evening just as ably as he did at that time, when he had an opportunity of defending the incandescent light, in a very signal manner, against the aspersion and detraction cast upon it by certain gentlemen in the west. Mr. Howell will now give us a paper on "The Maximum Efficiency of Incandescent Lamps."

(Mr. Howell read his paper. See page 203.)

ABSTRACT OF DISCUSSION.

Mr. S. S. Wheeler—I am very glad that Mr. Howell has given us the result of these experiments just as they came out. When slight variations are seen in experiments we have greater faith in their trustworthiness.

Mr. Joseph Wetzler—I would like to ask Mr. Howell if he can base calculations of both central stations and private plants on these diagrams and results; and if so, what the method of differentiation would be for separating the income or expenses of a station which at the same time supplied both power and light.

Mr. Howell—Mathematics knows no difference between a central station and an isolated plant. Of course, there is no difference. In regard to separating power and light costs, that is a matter of bookkeeping entirely. A man must know the conditions of his plant in order to tell how much of his power to charge against his motors and how much against his light. The cost of current includes every expense incurred in operating plant, except the price of lamps. I have to treat the matter in that way, because what I am after is the ratio of cost of lamps to total cost; so I take the cost of lamps by itself, and leave everything else with the cost of current. If you know how much your lamps cost and how much your current costs you have your total expense. A lamp is a known and definite thing, and everything else I have charged against current. In operating a motor, if you get the cost of current per horse-power per hour, all you have got to do is to charge against the lamps the horse-power consumed by them, and against the motors the horse-power consumed by them; and if you know the amount of electricity used in your motors and in your lamps, the proper proportion of that will be the cost of current in each case.

Mr. C. O. Mailloux—The lamps will not remain of normal candle-power, but, like all other things they grow old and reach a point where it is a question whether they are darker than the surrounding darkness; and I would like to ask Mr. Howell whether the life of the lamp, as it is taken here in the curves, means the time at which they break or the time at which they become so dark that they no longer give the full candle-power, without increased current. It would be very interesting to know just at what point the life is tabulated.

Mr. Howell—The tests begin with new lamps.

Mr. Mailloux—Then you take the point when the lamp is new, and let it burn until it burns out?

Mr. Howell—I do.

Mr. Mailloux—By the time it gets old it is not giving the same candle-power.

Mr. Howell—It makes no difference; the law applies just as well. You use the same data on your lamps as you do in determining your law. If you find you want lamps to give maximum efficiency, you take them when new. If you made your curve by taking data of the lamps half old, you would have to do the same thing here. If you start with one point of reckoning, you have to keep it up in all your calculations and experiments.

Mr. Upton—A 16 c. p. lamp, in practice commercially, fills a certain place, and, as measured by the makers, it can be taken as a commercial unit, and it is to this that the curves are applied. Three and one-tenth watts per candle is the best efficiency for the commercial man.

Mr. Mailloux—I think the significance of what I said is not fully understood. It occurred to me, looking at the lamp as constantly varying in its light-giving power, that it would modify somewhat the curve, which refers to the cost of lamps; for a lamp of low efficiency would, other things being equal, be preferable, because it would have a more uniform candle-power and would last longer before it became dim; and, on the other hand, a lamp of very high efficiency would soon become dark and would have to be changed. It is likely that a lamp of high efficiency would have to be changed long before it had broken, and what I meant to ask was, whether the cost was to be taken at the time when the customer had got tired of it and had called for a new lamp, or whether it included the growling you would allow him to do before you change the lamp.

Mr. Howell—In practice you find it nearly universal that lamps are taken down before they break. Of course that affects directly the cost of the lamps. Of course a lamp handed to you as being useless, is thrown into the receptacle for broken lamps, and is a dead lamp; so the tests include lamps only to the point at which they become useless.

Mr. Upton—The assumption on these tables is 600 hours. That means if you get that average light out of the lamp that the curve will hold true. Now, the intention of makers of incandescent lamps—I know it is with the Edison Lamp Company—is to make lamps which for 600 hours will give their full efficiency in candle-power. After that there is no guarantee and nothing said about it. We have now a set of new lamps—a hundred of them—which had run 400 hours, and only four of the lot had broken. It had always been the intention, and always the claim, that when a lamp is blackened that it should be destroyed. You notice that the Edison claim has been for a low guarantee, and one reason for that low guarantee is that the average light of the lamp is not how long it will stand on, but how long it will keep up good commercial efficiency, and what happens to the lamp after 600 hours is of no consequence as to this. The assumption is 600 hours at $3\frac{1}{10}$ watts per candle-power. I think Mr. Howell did not call attention to figure 2. I think great consideration should be given to it. It represents, as he says, five years experience on the part of the Edison lamp people, and I remember very well that in 1879, at Menlo Park, Mr. Edison spoke a great many times of the great value such a curve would have, and also of the exceeding difficulty of getting such a curve; because you have not only to pick out a large number of lamps from the same lot and test them under normal conditions, watching them closely all the time, but to get a good curve it requires many months and even years of constantly keeping lamps burning, and this represents the full experience of the Edison Lamp Company, which, just before Mr. Howell prepared this paper, was carefully gone over, taking in all the lamps which had ever been burned, and I think it is really stated safely to be within a two per cent. error.

Mr. Wetzler—I would like to ask if the speaker has ever verified the law for the candle-power of the lamp as referred to the current passing through it.

Mr. Howell—I have not, for the simple reason that current passing through a lamp in incandescent work is not something that we talk about. We talk about the pressure on the lamp always. No, I have never verified that with reference to currents. It is a very simple thing to do.

Mr. Wetzler—If we assume the resistance of the lamp to remain constant, it evidently is the same function whether we use current or potential.

Mr. Howell—We must not assume something that is not so; the current does *not* remain constant.

Mr. Mailloux—I would like to ask Mr. Howell if he has any data, or if he knows of observations which have been made tending to show clearly the difference in life of lamps run at the same watts per candle-power, using different currents. I suppose that we are all familiar with the statement which went the rounds of the press a year or two ago, to the effect that an alternating current added life to the filament of the lamp; that a lamp run at the same watts per candle-power, at the same efficiency, with an alternating current, would last longer than a lamp run with a continuous current. If that is true, it would be very interesting to have some data as to the cause of the difference? My experience with storage batteries has shown that the life of a lamp is undoubtedly increased at the same efficiency—that a lamp running at three watts per candle-power, for instance, with storage batteries, will last much longer than a lamp running at the same efficiency from a dynamo. How much the difference is I really cannot say. Now, perhaps Mr. Howell can give us information on that subject, which would be very welcome and useful.

Mr. Howell—To determine the life of any lamp there is one absolute necessity, and that is a constant pressure. During the five years in which that curve was determined, there was always one man who did nothing else but keep the pressure constant. You can do that with a dynamo, but you cannot do it with storage batteries—you cannot in practice. I have had a good deal of experience with lamps on storage batteries, and I am perfectly willing to be criticised when I make the statement that the pressure on a storage battery plant, as ordinarily installed, varies, I think, five times as much as it does on the average dynamo circuit; and that the life of lamps on a storage battery plant, as ordinarily installed and handled, is very much lower than it is on the average dynamo plant; due to nothing else than the simple impossibility of keeping their pressure anywhere. I mean that that is a defect in their methods more than anything else. They use their lamps and charge the battery at the same time, and have no means of keeping their pressure constant, and they do not do it.

Mr. Mailloux—I only wish to add that I am very sorry we did not happen to be fooling with the same battery. Probably that is the reason why Mr. Howell has found such a great difference. It was not the same battery; it was not handled the same way.

Mr. Howell—The handling of it has more to do with it than the battery has.

Mr. Mailloux—We have found that by using suitable precautions and devices it is possible to secure as constant (if not more constant) electromotive force with a storage battery as with any other source of electricity. I freely confess that I have had no facilities for making quantitative experiments or determinations by which I could get at the exact value of the difference to which I adverted.

Mr. Howell—It just occurs to me right here that I was sent to investigate the lamps in a storage battery plant. Of course I went into the place as a stranger and asked innocent questions. In this case I got the freedom of the plant and went down to talk with the engineer. I said: "Those lamps don't look very bright; do you call that a good light?" He said: "No; that isn't any good, but you ought to be here when the engine is running."

Mr. Mailloux—When you take into consideration that a storage plant that gives nominally about two volts per cell requires from two and four-tenths to two and one-half tenths for charging, and multiply that by sixty, you can readily perceive why the light was so much brighter when running the engine.

Mr. Howell—There is no question that the possibilities of the storage battery are very great. For laboratory work, where we want a constant current, there is probably no equal to it for a short time, or probably for any time; but for practical work, as storage batteries are installed commercially, they are very far from giving a constant pressure.

Mr. Franklin L. Pope—So far as I know, no accurate experiments have been made to determine the difference in light between a lamp run at an equivalent candle-power with an alternating and with a direct current; but I may say that when I was in England, about two years ago, there was some conversation among a number of electrical engineers one evening, in which that subject was brought up, and some one—I don't recollect who, but I think it may have been Professor Forbes—speaking of a plant that had been installed in Whiteley's large establishment at the West End, and worked directly by an alternating dynamo—I think it was a Ferranti machine—made the assertion very positively that the lamp showed a longer life with an alternating current than with a direct current, and the reason put forward to explain it was that with a direct current the hot carbon was something in the condition of an electrolyte and was more apt to throw off a deposit and disintegrate than when the current was continuously reversed. But I do not know whether there is anything in that or not. I simply state it as I heard it.

Mr. Howell—I think an argument drawn from one case or a few cases of that kind is hardly to be depended on very largely, because you take the identical lamps and put them on different plants, run from straight or alternating currents, you get different results, due to different handling. It is the hardest thing that I have ever undertaken to compare the lives of lamps. Now, as showing the difficulty and the misleading effect of the local conditions in a plant, when we first started in the business we made lamps of from 90 to 110 volts, and on our isolated plants we ran lamps from 95 to 100, most of them, and those lamps were all made at once. Now the man who put in our plants, and who was in charge of the work, found a good many plants giving good results and using 97-volt lamps. He found 96, 98 and 99 were giving bad results, and he drew the conclusion that the 97-volt lamps were better than 96 and 98. He drew that inference from facts determined from two or three lamps at each time. Now the voltage of the lamp had nothing to do with it. The conditions of operating the plant affected the lives in the various cases. If the man who was getting good results from 97 and the man who was getting bad results from 96 were to change their places, they would get the same as they did before. The lives of lamps are affected by every condition of running. To draw conclusions from a few lamps is misleading.

Mr. Upton—We had another instance of the finding of the relation of lives of lamps. This came from Shamokin, Pa. By breaking off the tip of a lamp under water you can fill the lamp, and you will obtain a little bubble there. This man broke the tips off a large number of lamps and concluded the larger the bubble the longer the life of the lamp. This satisfied him until we showed him that on the size of the opening depended the size of the bubble, and when you break it in mercury you cannot see the bubble at all. I think the question of alternating current and straight current in their effect on the life of lamps is an unsettled question. All our experiments have so far indicated negative results. The life is the same whether the current be straight or alternating. I do not think there are any experiments as yet proving a material difference between the two; that is where the conditions are thoroughly watched all through. With alternating currents it is very difficult to indicate the pressure.

Mr. F. L. Pope—I quite agree with Mr. Howell, that a deduction drawn from a few experiments has little, if any, value, and I merely mentioned the incident as current talk, without attaching much importance to it. I should not be at all surprised to find, after a proper investigation—and it is a matter of no small difficulty, as Mr. Howell says—I should not be at all surprised to find that there is little or no difference.

Mr. Mailloux—In the early experiments in car lighting that were conducted by a company here with storage batteries they very quickly found that they had to increase the efficiency of the lamp, because there would not be enough energy to make a round trip. At that time the lamps of three watts per candle power were not in commercial use. They were not to be had. So this company applied to the Edison company to have some lamps made. The Edison company said that they could make them lamps of any efficiency and that they would be glad to make them, but that they would not guarantee any life at all. I was not connected with the company at the time, but I understand that is the way it happened. They took the lamps and concluded that they would risk it; they let them break. They thought that lamps were cheaper than current, especially when the current came from storage batteries, and they put the lamps on. I know that some of those lamps were in use for over three months. They not only gave full voltage, but they sometimes got above it when the battery was extra charged and care was not taken to maintain constant electromotive force. It may be that the Edison company did not consider it wise for them to use that same lamp. I think it would have satisfied the test, with a reasonable life, with their own current.

Mr. Birdsall—As regards the life of a lamp when running above voltage I have found plants which have run the old Edison lamp—a 94-volt lamp—at 115 volts, and then they would give 900 hours light, and the men did not appear to think that there was very much lamp breakage even for that excess of voltage.

Mr. Upton—As to these curves which have been put on the board to-night, Mr. Howell asked me whether we should publish these results. We discussed it and concluded it was better to publish what we could about the relations between economies and lives of lamps. The time, we concluded, had come when the public should fully recognize that the mere claim of giving two watts, or two and-a-half watts, or three watts, or whatever it is per candle, means nothing, until these claims have been verified by long practice, and we know in the lamp business that no lamps can be put upon the market unless they have a large margin over the laboratory test, or otherwise your complaints and troubles

will more than counterbalance the gain, and these curves that Mr. Howell has presented here are based, I think, safely on commercial practice, and we have chosen in this case about three watts per candle as our normal rating, and we recommend it as embodying our experience and the recommendation of the Edison company for the best commercial practice.

Mr. F. L. Pope—Mr. President, there is a great deal of uncertainty in the photometric measures of lamps. Two or three years ago we heard a great deal about the remarkably efficient incandescent lamps that had been produced in England, and a gentleman of my acquaintance got some of them and undertook a photometric investigation of them, but he was not able to get so good results as had been obtained with them in England. As it happened, I was over there not long after that and made some inquiries, and found the trouble was in the system of measurement. My friend had measured them all around the horizontal circle, and the English photometers had only measured them at one angle, and that was the way they got the results which they advertised.

The President—We have reached the usual hour of adjournment. Should there be no further discussion on this very interesting and valuable paper adjournment will be in order.

I think we all feel greatly indebted to Mr. Howell for the trouble he has taken in preparing this paper and also to the Edison company that he has been enabled, and I may say permitted, to present to us information which has been accumulated at so great cost and expense, and which must be of the utmost benefit to all who are engaged in the business and profession of incandescent lighting in this country and abroad. I am sure that these results will be noted with interest not only in America, but throughout the world, wherever incandescent lamps are used.

The meeting was then adjourned.

ANOTHER IMPORTANT TELEPHONE DECISION.

Circuit Court of the United States,—District of Arkansas.

THE AMERICAN BELL TELEPHONE CO. *vs.* THE SOUTHERN TELEPHONE CO.

BREWER, J.—

When I came here I did not expect the burden of this case to fall on me, but thought I had only come to assist my brother Caldwell here and simply to advise with him. But the circumstances were such when I arrived that it seemed necessary that I should take the sole responsibility, and that he should look after other matter pending, aside from this case. I did not want to take the case. I avoid patent cases all that I can. And yet this happened to be one of those cases involving questions to which my attention has been directed as a matter of intellectual interest for the last two or three years, and from time to time as the opinions of the various courts have been announced I have examined each opinion and studied it with interest and curiosity as to the various questions presented and passed upon.

When this bill was filed no decision had been announced by the Supreme Court of the United States, although several opinions had been promulgated by several Circuit courts, and so a good deal of the testimony taken and presented in this cause was with reference to matters which it was apparently thought might be presented for examination here. But on the 19th of last month the Supreme Court decided the question, and that decision puts out of consideration many matters that would otherwise be fair subjects for discussion.

Of course the decision in that cause is not a final adjudication as between these parties. The proceeding there was *res inter alios acta* and not conclusive upon this litigation. Many questions of fact which, as between those parties, were settled by that decision—such as the question as to the priority of discovery—are not settled as between these parties by that decision. That question is still so far open that when that court has a new case before it, if brought between other parties and upon different testimony, it may declare that Mr. Bell was not the first discoverer and inventor. Thus the Supreme Court about two years ago, after a careful investigation, sustained what is known as the "Driven well" patent, but in the next year the court declared that patent void because the testimony showed the entirely new fact of two years public use which was not in the first case. Some years ago I sustained the Glidden patent for the barbed wire fence, and it is the only patent I ever sustained. Afterwards Judge Shiras held it bad because of a prior use and invention not shown in the case before me.

But it unquestionably appears from the decision of the Supreme Court that they upheld Mr. Bell's patent, and after carefully considering its construction they gave it a very broad scope.

In the present case the claim is not for the use of a current of electricity in its natural state as it comes from the battery, but for putting a continuous current in a closed circuit into a certain specified condition suited to the transmission of vocal and other sounds, and using it in that condition for that purpose. So far as at present known, without this peculiar change in its condition it will not serve as a medium for the transmission of speech, but with the change it will. Bell was the first to discover this fact, and how to put such a current in such a condition, and what he claims is its use in that condition for that purpose, just as Morse claimed his current in his condition for his purpose. We see nothing in Morse's case to defeat Bell's claim; on the contrary, it is in all respects sustained by that authority. It may be that electricity cannot be used at all for the transmission of speech except in the way Bell has discovered, and that therefore, practically his patent gives him its exclusive use for that purpose; but that does not make his claim one for the use of electricity distinct from the particular process with which it is connected in his patent. It will, if true, show more clearly the great importance of his discovery, but it will not invalidate his patent.

An effort was made in argument to confine the patent to the magneto instrument, and such modes of creating electrical undulations as could be produced by that form of apparatus, the position being that such an apparatus necessarily implied "a closed circuit incapable of being opened, and a continuous current incapable of being intermittent." But this argument ignores the fact that the claim is, first for the process, and, second, for the apparatus. It is to be read, 1, as a claim for "the method of transmitting vocal or other sounds telegraphically as herein described, by causing electrical undulations similar in form to the vibrations of the air accompanying the said vocal or other sounds, substantially as set forth;" and, 2, as for "the apparatus for transmitting vocal or other sounds telegraphically, as herein described, by causing electrical undulations, . . . substantially as set forth." The method, "as herein described," is to cause gradual changes in the intensity of the electric current used as the medium of transmission, which shall be exactly analogous to the changes in the density of the air, occasioned by the peculiarities in the shapes of the undulations produced in speech, in the manner "substantially as set forth;" that is to say, "by the vibration or motion of bodies capable of inductive action, or by the vibration of the conducting wire itself in the neighborhood of such bodies," which is the magneto method; or "by alternately increasing and diminishing the resistance of the circuit, or by alternately increasing and diminishing the power of the battery," which is the variable resistance method. This is the process which has been patented, and it may be operated in either of the ways set forth. The current must be kept closed to be used successfully, but this does not necessarily imply that it must be so produced, or so operated upon, as to be incapable of being opened. If opened it will fail to act for the time being, and the process will be interrupted; but there is nothing in the patent which requires it to be operated by instruments which are incapable of making the break.

If, for instance, in this case there was presented to this court something which was absolutely new in this litigation, something that was very clear and conclusive, clearly proved beyond question as a matter of fact and entirely conclusive in its effects, then this court might refuse an injunction, notwithstanding the decision of the Supreme Court or affirming the validity and determining the scope of that patent. But in all ordinary cases on an application for a preliminary injunction the decision of the Supreme Court must be accepted as conclusive, both as to the validity of the patent and as to the question of the scope or the extent to which the patent goes. That relieves me of much labor.

I understood the counsel in their argument to state that from previous decisions it must have been expected, and that it was expected by the profession generally that the Supreme Court, if it found against the validity and priority of Mr. Drawbaugh's claim, would sustain the Bell patents as broadly sustained as they have been sustained. This may have been the expectation and belief of the bar in the east, but I am inclined to think from the discussions by several members of the bar who have given this matter investigation, that was not the expectation here, and that the belief was that if the patent was sustained and Mr. Bell decided to be the first who made the invention, the patent would be so limited in law as to make it a patent for the particular apparatus described or for the particular and limited mode which was embraced and developed in the precise apparatus shown. But I think no man can read this opinion of the Supreme Court, and no man can compare that opinion with other deliverances of the courts upon patent cases without perceiving that, in language as clear and potent as it is possible for language to be, the court has affirmed the validity of the patent, and has decided its scope without limiting it to the mere apparatus, and have held that it extends to his whole method of reproducing vocal sounds. I believe that his method as he states it in his patent, and as the Supreme Court construes it, covers the whole matter of the telephonic transmission of speech, because the essential part of it consists in the transfer to the electric current, and the transfer by that current of the vibrating motions caused by the human voice in the utterance of speech.

Let me turn now to the opinion. The Chief-Justice says:

The important question which meets us at the outset in each of these cases is as to the scope of the fifth claim of the patent of March 7, 1876, which is as follows:

The method of and apparatus for transmitting vocal or other sounds telegraphically as herein described, by causing electric undulations, similar in form to the vibrations of the air accompanying the said vocal or other sounds substantially as set forth.

That is the idea of the transmission of these sounds by means of electrical undulations which are "similar in form" to the air vibrations that constitute the sounds to be transmitted. The court continued:

The question is not whether "vocal sounds" and "articulate speech" are used synonymously as scientific terms, but whether the sound of articulate speech is one of the "vocal or other sounds" referred to in this claim of the patent. We have no hesitation in saying that it is, and that if the patent can be sustained to the full extent of what is now contended for, it gives to Bell, and those who claim under him, the exclusive use of his art for that purpose, until the expiration of the statutory term of his patented rights.

In this art—or, what is the same thing under the patent law, this process, this way of transmitting speech—electricity, one of the forces of nature is employed; but electricity, left to itself, will not do what is wanted. The art consists in so controlling the force as to make it accomplish the purpose. It had long been believed that if the vibrations of air caused by the voice in speaking could be reproduced at a distance by means of electricity, the speech itself would be reproduced and understood. How to do it was the question.

Bell discovered that it could be done by gradually changing the intensity of a continuous electric current so as to make it correspond exactly to the changes in the density of the air caused by the sound of the voice. This was his art. He then devised a way in which these changes of intensity could be made and speech actually transmitted. Thus his art was put in a condition for practical use.

In doing this, both discovery and invention, in the popular sense of those terms, were involved; discovery in finding the art, and invention in devising the

means of making it useful. For such discoveries and such inventions the law has given the discoverer and inventor the right to a patent—as discoverer, for the useful art, process, method of doing a thing he has found; and as inventor, for the means he has devised to make his discovery one of actual value. Other inventors may compete with him for the ways of giving effect to the discovery, but the new art he has found will belong to him and those claiming under him during the life of his patent.

That is, the intensity of the current was changed in accordance with the form or character of each vibration. And then again the language of the court implies, what seems to me from my study of the telephone to be a necessary physical fact, that in no other way can electricity be actually made operative to convey those peculiar vibrations. That is the main idea of the patent. There must of course be something more than the bare idea; there must be some machine to make it practically useful, but the patent is not limited to the employment of it by that particular apparatus. The court said :

"It is again said that the claim, if given this broad construction, is virtually 'a claim for speech transmission by transmitting it; or, in other words, for all such doing of a thing as is provable by doing it.' It is true that Bell transmits speech by transmitting it, and that long before he did so it was believed by scientists that it could be done by means of electricity, if the requisite electrical effect could be produced. Precisely how that subtle force operates under Bell's treatment, or what form it takes, no one can tell. All we know is that he found out that by changing the intensity of a continuous current so as to make it correspond exactly with the changes in the density of air caused by sonorous vibrations, vocal and other sounds could be transmitted and heard at a distance. This was the thing to be done, and Bell discovered the way of doing it. He uses electricity as a medium for that purpose, just as air is used within speaking distance. In effect he prolongs the air vibrations by the use of electricity. No one before him had found out how to use electricity with the same effect. To use it with success it must be put in a certain condition. What that condition was he was the first to discover, and with his discovery he astonished the scientific world."

Then the court quotes from some of the scientific commendations, and adds : "Surely a patent for such a discovery is not to be confined to the mere means he improvised to prove the reality of his conception."

It follows, and this to my mind is supreme as to the scope of the patent, that by its terms and by the decision of the court it covers the idea of the transmission of the vibrations of articulate sounds by undulatory currents of electricity.

These undulations or vibrations are the means of reproducing human speech at a distant point, becase they repeat electrically the same vibrations. The sound vibrations are, so to speak, converted into corresponding and similar vibrations of electricity, as though these forces of nature, though different, were convertible, and what was done by the one would be, and in the telephone were copied by the other. The idea was that when the vibrations created by the organs of speech acted on the electrical current they set up in the electrical force the same variations or vibrations, transferred these vibrations to the electricity, which in turn transferred them to the distant point. That is the idea on which Mr. Bell's instrument is based.

The difference between putting into the current of electricity undulations which are copies of the vibrations caused by the human voice, and using a regular and uniform current of electricity merely broken up by intermissions, or what is called a make-and-break, as it is expressed, is very clear. Take the old Morse instrument. In that the currents of electricity are uniform; they are merely made and broken, and there is nothing like any change in strength. Suppose we load each barrel of a revolver with a bullet of the same size, density and shape, and shoot one after the other, they impact upon the object on which they strike with successive blows which are uniform, systematic and regular. Where a current of water flows through a pipe, if we suddenly turn a stop-cock we simply break the current; as soon as it is opened and the water gets going, it flows again with a uniform motion, and this makes only a similar impression upon a far-off object.

But Bell's idea of the transmission of sound is that the vibrations are irregular and different for each word, somewhat as if you put a paddle in the water and wave it backward and forward irregularly. Then the wave-like motion of the water is like that of the paddle. That is Mr. Bell's idea. The wave-like changes in his current are irregular, just like the irregular to-and-fro movement in the air which produces his electrical waves. That is what the Supreme Court says his patent is for. He takes a current of electricity, which is uniform and regular, and continuous in its flow, and changes that current by the vocal impulses, such as are made by articulate speech, so that the current, instead of being simply continuous and uniform, corresponds exactly with the variations of the vibrations in the air.

Looking at it from that standpoint, it seems to me impossible to transmit human speech by electrical currents otherwise than by giving to those currents variations harmonious with and corresponding to the various vibrations of the air. It would be impossible to do it by sending regular and uniform currents merely broken up. If you should merely break up a uniform current, preserving its uniformity, it would be a physical impossibility ever to transmit speech by means of it; for it is a physical impossibility ever to transfer human speech otherwise than by getting the current itself to correspond to the peculiarities of the vibrations which constitute that speech, and which the current must transfer.

That there is in all articulate speech something that may be called a pause between one vibration and another, and that that infinitesimal pause will cause a corresponding instant of no motion or no change in the electrical current which transmits that speech is obvious. When I speak there is not in one sense an unbroken and continuous flow of sound. In every vibration of the air there is an instant when, having moved in one direction it ceases to do that and begins to move in the other; and so in an electric current which copies that vibration, there would be the same corresponding infinitesimal break and flow again. And besides that, between each sound or between each word or each syllable there is a pause in the air vibrations, and so there would be in the electric undulations which copy them. But that is not a broken current like the current of the Morse telegraph. When we speak of a continuous current in the telephone we mean a current which has such continuity as the air vibrations and motions have in speech.

It was urged at the hearing that the defendant's instrument had breaks of current which accompanied the various changes in the motion of the instrument acted on by the voice. It was said that the use of the induction coil showed that there were breaks in the currents, and also that there were two separate circuits, the primary and the secondary, and that the current did not flow and was not continuous from one into the other. Neither of these considerations are new in this litigation. Both were presented to the Supreme Court. But suppose all that to be true, just as stated. If the Supreme Court had decided that there must be only one current, and that the current must be absolutely continuous, there might perhaps be force in that contention. But the idea which the Supreme Court rested on was that of a current continuous and undulating in the sense in which I have described it, like the vibrations of the air, corresponding to its motion, and not "merely" intermittent. It would not make any difference, in my opinion, if there were half-a-dozen currents co-operating with each other so that the transmitting current took up the undulations corresponding to the air vibrations and carried them to the distant point. The idea expressed by the Supreme Court is that stated by the language of the specification—causing and employing electrical undulations "similar in form" to the air vibrations accompanying the vocal or other sounds to be transmitted. That is the idea. That is the art or method which is patented; the same variations in the electricity as in the air—similar to the changes in the air vibrations, and co-extensive with them.

To one who has read this opinion of the Supreme Court, with that view of the operation by which speech is transmitted, there can be but one conclusion as to the fact that the various instruments which are used and are said to be used by these defendants infringe. Whatever else they do or do not produce, they produce electrical changes which correspond to the vibrations and sound waves caused by articulate speech, and those are the "undulations similar in form to the air vibrations," described in the patent.

Thus far I have very little trouble in reaching a view which disposes of this part of the case.

The other question is one that is more embarrassing, and that is whether a preliminary injunction under the circumstances of this case would be proper. These defendants engaged in this enterprise in the summer or fall of 1885. This suit was brought in the fall of 1887. For two years before this suit was instituted, the defendants had been in operation and had built up a business of some 400 telephones. The fact that it had established or was establishing its business was well known to the Bell company, and still no suit was instituted for a period of two years. Under these circumstances two questions arise.

Generally a doubtful question of fact ought not to be settled on ex-parte affidavits. In this application for an injunction the case is presented on both sides by affidavits, and affidavits are not very reliable testimony. The case, it is urged, ought to wait until the witnesses could be examined and cross-examined, and only after that full investigation, which is more certain of eliciting the truth, ought an injunction to be issued. At the hearing the important question which the counsel relied upon as doubtful, was whether the process by which their instruments transmitted speech consisted in the use of undulatory waves or of the absolute make-and-break of a current which was uniform between the breaks, and they urged that that question ought not to be settled on a preliminary investigation, or by any means short of a full hearing, upon the examination and cross-examination of witnesses.

Where there is a doubtful question of fact the court will generally wait until witnesses have been produced and been examined and cross-examined. And if this case was a case which turned upon the weight to be given to the testimony of witnesses on such a subject, the argument would be forcible.

Suppose that I entered possession of a tract of real estate, and having left it, came back twenty years after, and upon the question of an injunction the defendant claims a continuous occupation, and I produce affidavits and he produces affidavits as to

whether there was actual entry and possession by each twenty years ago. That presents a question that in the very nature of things may be doubtful, and affidavits on such a matter may control the courts very little. This is a question that particularly presents a subject for cross-examination of the witnesses. But I have had enough experience in patent cases to know there never was a patent of any intricacy in which experts could not be produced on either side—men of intelligence and scientific acquirements, ability and integrity who would file their affidavits on one side or the other. But no amount of that kind of evidence as a rule will overcome what the court can clearly learn from an intelligent examination of the instruments themselves. The examination of those instruments with the explanations given by Mr. Young and Mr. Storrow, on one side and the other, in regard to the respective apparatus, is testimony that is full and competent in this case. You see the instruments, and you examine them to ascertain the process with the explanations of these gentlemen, who are fully competent to understand it. This is not a case where the investigation is surrounded with doubtful questions of fact, which could be cleared up by cross-examination of the witnesses.

Another argument urged against this motion is that a man who claims land upon which he sees his neighbor trespassing, and on which he sees his neighbor expending money, believing that it is his own, and lets him go on without opposition, may lose his right to a preliminary injunction. A man who stands by and sees his neighbor go onto his land and dig a cellar and put in a foundation and build a house, and waits from day to day, and month to month, and year to year and says nothing to restrain him from the use and waste of his money, and afterwards wants to turn round and take his money and the products of his labor and time, does that which shocks any man's sense of right. If he knew this man was using his time, labor and money to improve his property, he should have tried to restrain him; then if the trespasser still persists, it is the trespasser's own fault.

The defendants claim that the plaintiffs did not bring their suit until two years after the defendants built their exchange, and that is the fact. But no definite length of time constitutes laches. This defense always depends upon the circumstances of the case. If these defendants had proceeded to make their investment, believing that they had a right to use their telephones and believing that no claim was made to the contrary; and had been led into this condition, by inaction and silence on the part of the plaintiffs with full knowledge of what the defendants were doing, of course it would be unfair to stop them now before the case is tried in the usual way.

But in this case the fact that Mr. Bell had these patents, and that he was insisting upon his claims in the broadest extent, and as broadly as he does now, and was carrying on the litigation in several courts of the United States, and that several courts in the various circuits had confirmed its validity and its scope as he contended for it, and that a number of these cases were pending in the Supreme Court of the United States, and that most earnest and vigorous proceedings were being carried on by the Bell company to enforce its claims, and that one department of the government was affirming frauds in the patents, and was about to institute proceedings for the purpose of canceling the patent—these matters were of common knowledge. But the defendants, in the face of those universally known facts, and it is proved with actual knowledge of the existence of the litigation and the decisions, and of the fact that litigation was pending in the Supreme Court of the United States which would sooner or later be determined, entered into this business. They say they believed that the patent would be decided to be void, and that they believed that the government suit would be a protection; and I have no doubt they believed this.

If the patent had been defeated in the Supreme Court there would be no injunction and they would be free. But this was one of the matters to be determined by the court of last resort. Under those circumstances can it be said, when these suits were finally determined in the Supreme Court and Mr. Bell was sustained to the fullest extent claimed by him here, that he should be answered here by the claim that as he had waited until his rights were determined, he was too late to enforce them; and because the defendants had infringed for two years during the litigation they were watching, they should not be interfered with six months or nine months or some other time afterwards. It is the case where, to use a common phrase, a man buys into a lawsuit and must take his chances of the result. For here the defendants knew all about the litigation and what the consequence of a decision by the Supreme Court must be, and based their expectations on the belief that the litigation would terminate adversely to Mr. Bell. But it has ended in his favor.

This case is of much importance, and I have heard several days' argument on the motion and given it all the consideration possible during the whole week. It is evident from what has been said that the plaintiffs are entitled to the preliminary injunction asked for, and it is granted.

.... To do a thing correctly, it is first necessary to understand what is to be done.—*Arthur M. Wellington.*

THE PATENT REFORM BILLS INTRODUCED TO CONGRESS BY THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

A BILL

To establish a Court of Patent Appeals of the United States, and to amend sections four thousand nine hundred and eleven, four thousand nine hundred and twelve, and four thousand nine hundred and fifteen, Revised Statutes, and section seven hundred and eighty, Revised Statutes, relating to the District of Columbia.

BE IT ENACTED, *by the Senate and House of Representatives in Congress assembled:*

SEC. 1. There shall be a Court of Patent Appeals of the United States, which shall consist of a Chief Justice and four Associate Justices, who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall hold office during good behavior. Any three of said Justices shall constitute a quorum.

SEC. 2. The Associate Justices shall take precedence according to the dates of their commission, or when the date of the commission of two or more of them is the same, according to their ages.

SEC. 3. In case of vacancy in the office of Chief Justice, or of his inability to perform the duties and powers of his office, they shall devolve upon the Associate Justice, who is first in precedence, until such disability is removed, or another Chief Justice is appointed and duly qualified. This provision shall apply to every Associate Justice who succeeds to the office of Chief Justice.

SEC. 4. The Justices of the Court of Patent Appeals shall receive the sum of eight thousand dollars each per annum, to be paid monthly.

SEC. 5. The Court of Patent Appeals shall have power to appoint a Clerk and a Marshal for said Court, and a Reporter of its decisions.

SEC. 6. One or more deputies to the Clerk of the Court of Patent Appeals may be appointed by the Court on application of the Clerk, and may be removed at the pleasure of the Court. In the case of the death of the Clerk, his deputy or deputies shall, unless removed, continue in office and perform the duties of the Clerk in his name until a Clerk is appointed and qualified; and for the default or misfeasance in office of any such deputy, whether in the life-time of the Clerk or after his death, the Clerk and his estate and the sureties on his official bonds shall be liable, and his executors and administrators shall have such remedy for such default or misfeasance committed after his death, as the Clerk would be entitled to if the same had occurred during his life-time.

SEC. 7. The Marshal shall be entitled to receive a salary at the rate of two thousand dollars a year. He shall attend the Court at its sessions, shall serve and execute all process and orders issuing from it, or made by the Chief Justice or an Associate Justice in pursuance of law, and shall take charge of all the property of the United States used by the Court or its members. With the approval of the Chief Justice he may appoint assistants and messengers to attend the Court, with the compensation allowed to officers of the House of Representatives of similar grade.

SEC. 8. The Reporter shall cause the decisions of the Court of Patent Appeals, made during his office to be printed and published within six months after they are made, and within the same time, shall deliver three hundred copies of the volumes of said report to the Secretary of the Interior. And he shall, in any year when he is so directed by the Court, cause to be printed and published a second volume of said decisions, of which he shall deliver in like manner and time, three hundred copies.

SEC. 9. The Reporter shall be entitled to receive from the treasury an annual salary of twenty-five hundred dollars, when his report of said decisions constitutes one volume, and an additional sum of fifteen hundred dollars when, by direction of the Court, he causes to be printed and published in any year a second volume. But said salary and compensation respectively shall be paid only when he causes such decisions to be printed, published and delivered within the time and in the manner prescribed by law, and upon the conditions that the volumes of said report shall be sold by him to the public for a price not exceeding four dollars a volume.

SEC. 10. The three hundred copies of the reports of the Court of Patent Appeals shall be distributed by the Secretary of the Interior as follows: To the Commissioner of Patents forty copies, and the balance as provided in section 683 of the Revised Statutes for the distribution of the Supreme Court reports.

SEC. 11. The Court of Patent Appeals shall hold at the seat of government one term annually, commencing on the second Monday in October, and such adjourned or special terms as it may find necessary for the despatch of business.

SEC. 12. If at any session of the Court of Patent Appeals a quorum does not attend on the day appointed for holding it, the Justices who do attend may adjourn the Court from day to day for twenty days after said appointed time, unless there be sooner a quorum. If a quorum does not attend within said twenty days, the business of the Court shall be continued over until the next appointed session; and if during a term, after a quorum has assembled, less than that number attend on any day, the Justices

attending may adjourn the Court from day to day until there is a quorum, or may adjourn without day.

SEC. 13. The Justices attending at any term when less than a quorum is present, may, within twenty days mentioned in the preceding section, make all necessary orders touching any suit, proceeding or process, depending in or returned to the Court, preparatory to the hearing, trial or decision thereof.

SEC. 14. The Court of Patent Appeals of the United States shall have appellate jurisdiction in the cases hereafter specifically provided for without regard to the sum in controversy:

1. From the Circuit Courts of the United States and from the Supreme Court of the District of Columbia in all cases touching patents, copyrights, trade-marks and labels.

2. From the Commissioner of Patents in all cases touching patentability of inventions, priority of invention among several claimants for patent upon the same invention and the judicial practice of the Patent Office, also all cases touching the registration of trade-marks or labels and the rights of conflicting claimants therefor.

SEC. 15. From and after the passage of this Act, there shall be no appeal from the Circuit Courts of the United States in cases touching patents, trade-marks, copyrights or labels, to the Supreme Court of the United States directly, but all such cases formerly appealable to the Supreme Court shall be heard on appeal by the Court of Patent Appeals.

SEC. 16. There shall be a right of appeal from the Court of Patent Appeals, to the Supreme Court of the United States in all cases which individually involves $100,000 or more, exclusive of costs; and an appeal may be taken by the defeated party, to the Sureme Court of the United States from any final judgment or decree of the Court of Patent Appeals, when the latter Court deems the questions involved to be sufficiently important and sufficiently doubtful, to justify such an appeal, and therefore consents that such an appeal be taken.

SEC. 17. All cases touching patents, trade-marks, copyrights or labels, now pending before the Supreme Court of the United States awaiting trial may, at the option of the parties interested, be transferred to and heard by the Court of Patent Appeals

SEC. 18. When any Judge of the Court of Patent Appeals, resigns his office after having held his commission as such, at least ten years, and having attained the age of seventy years, he shall, during the residue of his natural life, receive the same salary which was by law payable to him at the time of his resignation.

SEC. 19. Section four thousand nine hundred and eleven of the Revised Statutes shall be, and hereby is amended so as to read as follows: If such party is dissatisfied with the decision of the Commissioner he may appeal to the Court of Patent Appeals of the United States.

SEC. 20. Section four thousand nine hundred and twelve of the Revised Statutes shall be, and hereby is amended so as to read as follows: When an appeal is taken to the Court of Patent Appeals the appellant shall give notice thereof to the Commissioner, and file in the Patent Office, within such time as the Commissioner shall appoint, his reasons of appeal, specifically set forth in writing.

SEC. 21. That section forty-nine hundred and fifteen of the Revised Statutes of the United States is hereby repealed.

SEC. 22. That section seven hundred and eighty of the Revised Statutes, relating to the District of Columbia, is hereby repealed.

SEC. 23. All Acts or parts of Acts inconsistent with the provisions of this Act are hereby amended so as to be consistent therewith.

A BILL

To amend sections four hundred and seventy-six, four hundred and seventy-seven, of the Revised Statutes of the United States.

BE IT ENACTED, *by the Senate and House of Representatives in Congress assembled,*

That section four hundred and seventy-six, and four hundred and seventy-seven of the Revised Statutes of the United States, be hereby amended so as to read:

"SEC. 476. There shall be in the Patent Office a Commissioner of Patents, one Assistant Commissioner, and three Examiners in Chief, who shall be appointed by the President, by and with the advice and consent of the Senate. The Commissioner of Patents shall hold office for six years from the date of his appointment. All other officers, clerks and employés authorized by law for the office shall be appointed by the Secretary of the Interior, upon the nomination of the Commissioner of Patents."

SEC. 477. The salaries of the officers mentioned in the preceding section shall be as follows:

The Commissioner of Patents, eight thousand dollars a year.

The Assistant Commissioner of Patents three thousand dollars a year.

Three Examiners in Chief, three thousand dollars a year each.

.... IT has become an axiom among experienced electric station managers that the money is made or lost between the coal-shovel and the belt.—*William Lee Church.*

THE WESTERN ELECTRIC COMPANY'S NEW FACTORY.

The new factory of the Western Electric Co. in New York will occupy the south-east corner of Greenwich and Thames streets—the frontage being 119 feet on Thames street and 83 feet on Greenwich street. The building will be of light-colored brick and terra-cotta, having nine stories above the basements. The old structures on these lots are now being demolished and removed preparatory to the erection of the new factory. The Western Electric Co. will have their building ready for occupancy on the expiration of the lease of their present factory building, 70–76 Trinity Place, April 1, 1889.

Among the buildings now being torn down is one of some historic interest. It was built and occupied as a residence by Mayor Arcularius in the early part of this century. The site is well chosen, being in close proximity to the location where the company's large business has been conducted for 10 years. The new building will be fire-proof throughout, and will be constructed under the supervision of Mr. Cyrus L. W. Eidlitz, architect, who has made plans and designs combining admirable provision for factory requirements with a very imposing and tasteful exterior. The offices will, with much good sense, be located on the top floor. The building is estimated to cost about $200,000.

PERSONAL MENTION.

MR. D. H. BATES has connected himself with the Electrical Accumulator Co. as general manager of their business. Mr. Bates has won distinction as an executive officer in the telegraph service for some 20 years past, and will doubtless make as gallant and vigorous a leader in the Accumulator company's business, as he did in that of the Baltimore and Ohio Telegraph Co.

MR. GEORGE B. PRESCOTT, JR., has accepted an appointment as electrician to the Electrical Accumulator Co., and will have his office at the headquarters of that company, No. 44 Broadway, New York. His technical acquirements and extensive laboratory practice qualify Mr. Prescott admirably for the duties assumed by him in the commercial development of storage batteries.

MR. ANTHONY RECKENZAUN, after spending nearly a year in America, has returned to England. His departure will be much regretted by his American acquaintances and friends. His large experience in Europe with storage batteries and with electric traction, has been called into profitable service here in the work of Mr. Wm. Wharton, Jr., at Philadelphia, and of the Electrical Accumulator Co., of New York. His presence at meetings of electrical associations has always been welcome, while his contributions and remarks in discussion have been very useful and suggestive. It is to be hoped that Mr. Reckenzaun will return to the United States at no distant day.

THE DAFT COMPANY NOT SELLING OUT.

We are informed that there is no truth whatever in the rumor that the Daft company is about to be sold out to the Thomson-Houston company, recently published in another journal. Mr. Hawksworth, of the Daft company, authorizes us to say that there has been no offer, no negotiation, not even a thought of selling out. The Daft company proposes to take care of its own business and to hold its own among competitors.

REMOVALS.

JARVIS B. EDSON has removed from 91 Liberty street—where for 14 years he has conducted business in supplying his recording steam gauges—to No. 145 Broadway and 86 Liberty street (the old telegraph corner).

HENRY CONNETT, patent solicitor and expert, removes from Temple Court, to offices in the new Vanderbilt building, No. 132 Nassau street.

WELDING RAILS BY ELECTRICITY.

An exchange states that a Baltimore electrician has invented a method of welding steel rails by means of electricity. The ends of the rails after they are placed in the track are welded together through the application of a transformed electric current, and are afterward tempered so as to make the joint as hard as the rest of the rail. The welding apparatus is carried on the pilot of an engine or on a construction car, and it is claimed that a joint can be made in less than half a minute. The inventor proposes to thus make continuous rails a quarter of a mile in length, having expansion joints only at intervals of that distance, the rails being fastened at the centre so as to expand in both directions. This plan, if successful, would settle the great Fisher rail joint question, but the accumulated expansion and contraction in such long lengths of solid rail would be formidable.

ELECTRIC LIGHT AND POWER.

THE NASHVILLE JENNEY ELECTRIC LIGHT AND POWER CO. has been fully organized with A. L. Landis, Sr., president, and A. L. Landis, Jr., secretary and treasurer. The right of way has been granted through the streets of Nashville, and the company will be prepared to receive bids on machinery, etc., within 50 days.

THE LARAMIE ELECTRIC GAS LIGHT AND FUEL CO. is now running two 25 h. p. and one 20 h. p. and several smaller motors, all of Sprague make. They are on the 220-volt Edison circuits. The two 25 h. p. motors are driving a flour mill of 100 barrels capacity, and the 20 h. p. runs spike machines, nut pressers, bolt headers, lapping and threading machiney in a rolling mill. The three large motors earn together about $425 a month, while the rate for the smaller ones is about $15 per h. p. per month. The secretary and manager of the company is Mr. R. M. Jones.—*Electrical World.*

THE PACIFIC MOTOR COMPANY, of San Francisco, Cal., has 700 motors now in use, and is employing five circuits.

W. W. SLATTER, electrician and superintendent of the Central Pacific electric block system at Oakland, Cal., is replacing all oil lamp signals by Swan incandescent lamps on an arc circuit. There are forty trains daily running over this block after dark, and the greatest care is taken to keep all the colored lamps lighted to prevent accidents. It was very difficult to accomplish this when a strong wind was blowing. The change to the electric lights dispenses with two men to clean lamps.

THE reported negotiations for the sale of the Van Depoele company's business to the Thomson-Houston Electric Co. have been consummated.

AT Wheeling, W. Va., the board of gas trustees are about to install an electric light plant at a cost of some $20,000.

THE SCHUYLER ELECTRIC CO. has nearly completed the 200 arc light plant for the Mt. Morris Electric Light Co., of New York.

MANUFACTURING AND TRADE NOTES.

THE WESTINGHOUSE ELECTRIC CO. has declared a dividend of one and one-fourth per cent. for the quarter ending May 1st. The net earnings for the quarter are said to be between $90,000 and $100,000.

THE EDSON PRESSURE RECORDING GAUGE has been in use for some time at the Edison Machine Works, Schenectady, where a second instrument has just been ordered.

MR. WM. LEE CHURCH, of the Westinghouse Electric Co., says: "Texas is advancing in the use of electric light very rapidly. We have more central stations there than in any other state of the Union. We have only lately established stations at Houston and Marshall. The chief reason for this appears to be that the cost of coal there is considerable, which makes artificial gas accordingly expensive.

MESSRS. J. H. BUNNELL & CO. promptly recovered from the interruption attendant upon their recent disastrous fire, and are again about as busy as ever in filling orders.

THE WESTINGHOUSE ENGINE.—Very long continuous runs made by steam engines are considered rare, over a week, or several weeks being regarded as long runs. The Westinghouse engine, has, we are informed, increased such runs, in many instances to a number of months. The last public notice of a long run made by a Westinghouse engine was an instance where a certain engine ran 11 months without stopping, at a speed of 300 revolutions. The most remarkable record, however, has recently developed in the works of the Pittsburgh Gas Light Co., where a 10 h. p. Westinghouse engine ran continuously for 13 months, running at about 500 revolutions per minute, and in that time making 288,000,000 revolutions without the throttle valve being once closed, and it is still running.

POINTERS.

.... PEOPLE do not seem to realize that lamps do not behave like resistance; they flicker to some extent, especially if the carbons are thin. This makes them apparently run at a higher efficiency and break sooner.—*J. Swinburne.*

.... THE electrical support of the bird in the air is maintained on the effort of nature to form an equilibrium between the bird and the electricity of the air. Hence the utility of the electro non-conductibility of feathers. The fluid is expelled from the bird by muscular action, the elimination taking place at the multiple points of the wings and tail. The return of the electricity is prevented by the non-conductibility of the feathers. The loci of the force, that serves as a support of the bird, lie in the struggle of the electrical fluid to overcome the electrical vacuum in the bird. —*G. P. Hachenberg, M. D.*, of Texas, on "The Electro-Operations in the Flight of Birds" (written for the *Electrical Review*).—*Electrical Review*, New York, April 28.

ELECTRIC STREET RAILWAYS IN AMERICA

Now in Operation.

Notes.

THE DAFT COMPANY have taken a contract for the equipment of the Meriden Horse Railroad Co. The road is five miles long, and will run 12 cars. It is expected to have the road running in the early summer. This company also have a contract for 10 additional cars for the Asbury Park road for the coming season.

TESTS with the storage battery cars of the Electrical Accumulator Company are being made by the North Baltimore Passenger Railway Co.

THE ELIESON motor is being tried on the Buffalo Street Railroad Co.

THE MCGAVOCK AND MOUNT VERNON, an important road at Nashville, Tenn., has decided to adopt electric traction.

ELECTRICAL traction is soon to be introduced at Columbia, S.C.

THE DAFT electric road at Easton, Pa., is likely to be extended.

CONTRACTS for an electric road at Flushing, N. Y., have been given out.

THE new storage battery car of the Philadelphia Traction Company, which they claim will revolutionize the street railway service of the country, is kept under lock and key.

THE elevated lines in New York carried 158,963,232 passengers in 1887, an increase of 43,853,641, or over 35 per cent. over the figures of 1886.

THE surface roads running north and south carried in 1887, 175,204,439 passengers, a loss over the preceding year of about 5.75 per cent. Mechanical or electric traction is the only salvation for the surface lines.

The Street Railway Journal reports 1,198 miles of street railway built in the United States in 1887, and $3,601,000 expended in improvements. As much more is already under contract for 1888.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From March 20 to April 17, 1888 (inclusive).

Alarms and Signals:—*Electric Annunciator*, B. N. Botts, 379,758; *Tele-Thermometer*, F. J. Dibble, 379,766, March 20. *Electric Annunciator*, C. S. Young & G. E. Painter, 380,010. *Non-Interfering Signal Box*, F. W. Cole, 380,022. *Fire-Signal and Burglar-Alarm.* J. E. Church, 380,186. *Fire and Burglar Alarm System*, W. A. Barnes, 380,241, March 27. *Electro-Magnetic Signaling Device for Mines*, L. McK. Bullitt & O. C. Greene, 380,382. *Dust-Proof Thermostat*, A. S. Kissell, 380,394. *Semaphore Signal Apparatus*, F. Stitzel & C. Weinedel, 380,409. *Municipal Signaling*, M. Morris, 380,655, April 3. *Municipal Telegraph Apparatus*, J. C. Wilson, 380.778. *Municipal Telegraph*, same, 380,779. *Electrical Speed Indicator*, F. W. Schlepegrell, 380,824, April, 10. *Electric Bell*, F. B. Wood, 381,314, April 17.

Conductors, Insulators, Supports and Systems:—*Elevated Railroad and Conduit for Electric Wires, etc.*, A. C. Oehrle, 378,904, March 20. *Machine for Dressing Covered Electrical Conductors*, W. H. Sawyer, 380,053. *Apparatus for Threading Wires or Cords Through Flexible Tubes*, same, 380,054. *Conduit for Electric Railways*, S. D. Field, 380,103. *Electric Conductor*, E. G. Acheson, 380,157. *Manufacture of Electric Conductors*, E. G. Acheson & B. F. Anderson, 380,158. *Insulated Electrical Conductor*, W. A. Phillips, 380,295, March 27. *Machine for Covering Wire with Layers of Different Materials*, J. T. Van Gester, 380,610, April 3.

Distribution:—*System of Electrical Distribution.* T. A. Edison, 379,772, March 20; 380,101 and 380,102, March 27. *System of Electrical Distribution*, W. H. Hart & J. T. Goodfellow, 380,757. *System of Electrical Translation*, R. Belfield, 380,845 and 380,846. *Central Station for Alternate Current System of Electrical Distribution*, O. B. Shallenberger & H. M. THE
ELECTRICAL ENGINEER.

Conducted by F. L. POPE AND G. M. PHELPS, JR.

PUBLISHED MONTHLY AT

11 Wall Street, New York City.

TERMS OF SUBSCRIPTION.

United States and Canada,	per annum,	$3.00
Four or more Copies, in Clubs (each)	"	2.50
Great Britain and other Foreign Countries within the Postal Union	"	4.00
Single Copies, -		.30

[*Entered as second class matter at the New York, N. Y., Post Office, April* 9, 1888.]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. VII. NEW YORK, JUNE, 1888. No. 78.

NOTICE OF REMOVAL.

The offices of THE ELECTRICAL ENGINEER were removed May 1, from 115 Nassau street to 11 WALL STREET, New York.

By arrangement with the ELECTRICAL WORLD *of New York and with* THE WESTERN ELECTRICIAN *of Chicago, the publishers are enabled to offer either of those weekly journals, together with* THE ELECTRICAL ENGINEER, *for one year to new subscribers for* $5.00, *or the three journals for* $7.50.

NOTICE.

The proprietors and publishers of the ELECTRICAL ENGINEER *discontinue the title,* THE ELECTRICAL PUBLISHING CO., *from June* 1. *The business will be conducted, from that date, under the name of* THE ELECTRICAL ENGINEER. *All communications and remittances should be addressed accordingly.*

THE EDISON ELECTRIC LIGHT PATENTS.

A DECISION has been rendered by Judge Wallace of the United States Circuit Court in favor of the defendants, in the suit of the Edison Electric Light Co., against the United States Electric Lighting Co., for an injunction to restrain an alleged infringement of Edison's patent for an improvement in dynamo-electric machines. This was one of 26 suits instituted by the Edison company some three years ago against the same defendant. The importance of the decision lies in the fact that this was selected as a test case, and the result virtually determines the fate of at least a dozen more of Edison's patents, including three which relate to the incandescent lamp, and are regarded as fundamental. Instead of making answer to the bill of complaint in the case referred to, the defendants interposed a plea, contending that the patent had expired by reason of the expiration of a prior Austrian patent for the same invention. Judge Wallace sustained the plea and refused, on this ground, to grant an injunction, leaving the Edison company to take testimony, and show, if they can, that the invention of the Austrian patent is not the same as that of the United States patent, or that the Austrian patent did not expire, within the meaning of our statute, at the termination of its first year. This last point has already been twice decided in other cases, in which a similar state of facts existed, and the patents involved were adjudged to have expired. Hence it will be seen that the prospect of the Edison patents being ultimately sustained, is, to say the least, not a very encouraging one. A number of suits have been instituted against the Westinghouse Electric Co. and other defendants in which precisely the same issues are involved, and the results of which will necessarily be determined by the result in the test cases.

The attorneys who had charge of Mr. Edison's patent interests in the early stages of the development of his electric light inventions, unfortunately exhibited far more zeal than discretion in attempting to secure to their client a monopoly of electric lighting throughout the civilized world. The value of the rights and franchises which have, in all probability, been made nugatory by their ill-advised and hazardous procedure with reference to foreign patents is almost beyond calculation. It practically, at least as far as the Edison patents are concerned, throws the incandescent lamp manufacture open to the public in this country. It is certainly singular in view of the early day at which Mr. Edison entered this field of invention, and the enormous number of patents which he has taken out, that the essential features of the system should have received such inadequate protection.

THE subjoined extract from a letter written by an electric lineman to the coroner who is endeavoring to fix the responsibility for the death of lineman Murray, who was instantly killed a few days since while in the discharge of his duties, contains the unvarnished truth.

> All electric companies, since the passage of the subway law, have been doing slipshod, temporary work. There are no pains taken with any of the work in either telephone, telegraph or electric light, and the number of dead, crossed and broken wires is consequently on the increase.

Before proceeding to heap unsparing condemnation upon the heads of the electric companies, it may, however, be well to consider that their structures were erected in the streets of New York by permission of the public authorities, and to fulfill the public requirements; that by subsequent legislation this property has been practically confiscated, and outlawed. It would be singular, if, under these circumstances, the electric companies should feel disposed to spend any more money than they can help in repairing and improving property which may be rendered worthless to them at a day's notice.

This is but one of the results of hasty and ill-considered legislation in response to so-called "public opinion," manufactured by interested parties having private axes to

grind, and expounded by an untrammeled press, the conservator of our liberties, at the reasonable rate of one dollar per line. But the audience may as well keep their seats; the farce is not nearly over yet.

MAYOR HEWITT has, so to speak, shaken the dust of the subway commission off his feet. No one can blame him very much. The Mayor is not devoid of a sense of humor and has perhaps had some real enjoyment of the grotesque out of the meetings of the queer collection of persons who, by act of legislature and appointment of the Governor, masquerade as an engineering commission, and are called the Board of Electrical Control. But the fun of the thing probably proved insufficient compensation for the outrage to the sense of fitness and of the intelligent adaptation of means to ends, involved in the formation and career of the commission. Just why, toward the end of the nineteenth century, a political hack, a theatre agent and a presumptuous young attorney, should have been given charge of providing a great city—far exceeding all other cities in the scope and magnitude of its electric service—with a proper system of electric conductors underground, may become a question of some interest to the antiquarian curiosity of a distant future. However difficult the riddle may prove to the completely civilized denizens of the well governed city of two or three hundred years hence, the answer is not far to seek to-day.

CONSIDERABLE unnecessary surprise has been manifested by the unthinking, respecting the action of the New York board of aldermen in refusing permission to the Fourth avenue railway company to equip their line with electric motor cars propelled by storage batteries, owing, as the city fathers are careful to explain, to the danger arising from accumulations of electricity. But it must not be forgotten that many of the members of this body of scientists are chemists of no ordinary ability; as a matter of fact, most of them owe their positions to this very circumstance. Hence they may claim to speak with a certain authority.

The recollection of certain occurrences, not wholly unconnected with the annals of another street railway project in this city, prompts the suggestion that every vestige of danger from these batteries might possibly be removed by the judicious application, not to the batteries, but to the scientists, of a powerful solvent, vulgarly known as "boodle."

THE Institute of Electrical Engineers is to be congratulated upon its choice of Mr. Edward Weston as president for the year just begun. The honor of the election is not less to the Institute than to Mr. Weston, whose fitness to preside over a society so representative of theoretical and industrial electricity as the Institute has become will be everywhere recognized. To the retiring president, Mr. T. Commerford Martin, a heavy debt of gratitude is due for his untiring and judicious labors of the past year in furthering every interest of the organization. The published transactions and the annual report of the secretary at the recent meeting attest the work and progress of the Institute for the year just closed.

The attendance at the general meeting was very gratifying, the audience room of the Civil Engineers' Society being well filled by members and friends; many having come from distant points. All were amply repaid for their attention in the timely and instructive character of the papers and discussions, and in the opportunity for social intercourse afforded by the recess and luncheon.

For the purpose of giving the entire proceedings of the annual meeting, including all the papers read and their discussion, we increase the size of our present number.

MR. GEO. H. STOCKBRIDGE's paper on the proposed patent conrt was both timely and apt. He wisely confined himself to a single feature of the administration of the Patent Office, and by exhibiting a series of conflicting rulings and consequent changes of practice, see-sawing back and forth for some years, offered a cogent argument in support of the bill creating a court of patent appeals now before Congress, at the instance of the legal committee of the National Electric Light Association.

IF there be any prospective investors in primary battery companies on this side of the Atlantic, it will not be amiss for them to read Mr. F. B. Crocker's paper on the "Possibilities and Limitations of Chemical Generators of Electricity," read before the Institute of Electrical Engineers, and printed in our present issue. Its perusal should incline them to keep their dollars in their pockets for a while yet.

"DEAD" wires are too fast becoming *deadly*. We are glad to be able to note two instances of a systematic and thorough overhauling of circuits and removal or proper securing of all unused conductors. The Boston and Albany Railroad Co. has undertaken to clear up all wires throughout its road; and at Troy, N. Y. the electric light, the telegraph and telephone companies have united in an inspection and overhauling of all their wires, removing all superfluous and dangerous conductors. Let this good work spread. It seems not unlikely, that in some localities the expense of such work might easily be recovered in the value of unused wires taken down, to say nothing of any higher motive than economy.

OWING to the discovery of some inaccuracies in the text and illustrations of Mr. Tesla's very important paper, read before the Institute of Electrical Engineers, May 16, as given to the press and published already in several journals, we have delayed the issue of the ELECTRICAL ENGINEER for June, awaiting a revision of both text and illustrations under the direction of the author.

THE Supreme Court of the United States, before adjourning for the term, refused a motion for a rehearing in the telephone case, made by counsel for the People's (Drawbaugh) company, on the ground that no one of the judges who concurred in the majority opinion joined in the request. This may be looked upon as the final settlement of this most extraordinary controversy.

OUR very interesting contemporary, the *Progressive Age and Water Gas Journal*, now a semi-monthly, has removed its offices from Philadelphia to New York. The number for May 15th comes to us in a new and handsomer cover. No journal treating of illumination can ignore electricity. The *Progressive Age* always contains a page or two of electrical notes.

A STATEMENT which has recently been published in the newspapers, that overtures had been made by the Edison Electric Light Co. to the Westinghouse Electric Co., looking to a consolidation of interests, was at once officially contradicted in the Pittsburgh papers by the last named company. We have the best authority for saying that the story is entirely without foundation.

OWING to the pressure on our columns this month, notwithstanding an addition of 8 pages, we are compelled to omit some and defer other matter which we would be glad to print. We have to lay over till July the papers of Mr. Badt and Mr. Cutter, continuing the discussion of "Alternate *vs.* Continuous Currents" before the Chicago Electric Club.

OBITUARY.

GEORGE M. PHELPS.

"Whatever he touches he beautifies." These words were once fitly spoken by the lamented President Orton, of the Western Union Telegraph Co., of the artist-mechanician, George May Phelps, who died at his home in Brooklyn, on the 18th of May, 1888.

The memory of one who for so many years has been conspicuously identified with the progress of electro-mechanics, should receive a more fitting tribute than can be given in the necessarily brief space at our disposal.

In his personal characteristics, Mr. Phelps evinced many sterling traits of the sturdy New England ancestry from which he sprung. He was deliberate, thoughtful and reflective; but having determined upon a course of action, was persevering and persistent to the verge of obstinacy. To him difficulty presented itself merely as a thing to be attacked and overcome. To yield to it was apparently the last thing to enter his mind. With mental traits such as these, allied, as they were in the case of Mr. Phelps, with an inborn skill and delight in handicraft, the character of the man and his work could hardly have been other than it was.

Born in Watervliet, N. Y., March 19th, 1820, he early found congenial employment at Troy, N. Y., in the shop of his uncle, Jonas H. Phelps, a skillful maker of surveying and astronomical instruments. He learned the trade and acquired an unusual deftness and accuracy of eye and hand as a workman; this never left him till his physical strength broke down a few years ago—and enabled him when he found himself in charge of large shops, to take the tools from the hand of any workman—from the smith to the finisher of small pivots—and instruct him by example. At the age of 30, we find him carrying on a modest business, making models and light machinery, on his own account, in the same city. In 1852, the era of vigorous competition between the rival telegraphic systems of Morse, Bain and House, was at its height, and the difficulty of getting instruments manufactured as fast as they were needed, was becoming, by reason of the limited number of skilled workmen then in the country, a very serious one. The type-printing telegraph of Royal E. House a marvel of ingenuity and efficiency, for that day, but complicated and costly in its construction, could only be made in New York, and at one establishment, the limited output of which was quite inadequate to meet the requirements of the service. Struck with the unusual skill exhibited in some specimens of the handiwork of Mr. Phelps, the managers of the "House line" urged him to undertake the difficult task of manufacturing their apparatus. Accordingly the firm of Phelps & Dickerman was formed, the new partner supplying the additional capital needed, and the work was successfully prosecuted for some years. In 1856 the House lines fell into the hands of the New York, Albany and Buffalo (Morse) Co., and the use of the printing instruments was discontinued. But as it turned out, the last word in printers had not been said. A new apparatus, based upon a principle wholly unlike that of House, had been conceived and partly worked out by David E. Hughes, then a teacher of music in Kentucky. While yet in an inchoate condition, but obviously possessing great potential merits, the invention was taken up by that restless and energetic promoter of telegraphic schemes, D. H. Craig, who succeeded in selling it at a round price to a group of New York capitalists, among whom was the late Peter Cooper. These men at once organized a telegraph company, principally, as it would seem, in order to utilize their purchase. This was the inception of that vigorous and successful enterprise, the American Telegraph Co., which in 1856, purchased the Phelps & Dickerman factory, and installed Mr. Phelps as its superintendent, having already placed Hughes's invention in his hands, to be adapted by him to the exacting requirements of the commercial telegraphic service.

In 1857 the new instrument made its advent, and at once met with deserved favor. In reorganizing the original machine, Mr. Phelps had retained the fundamental conception of Hughes, the unintermittent and synchronous rotation of the transmitter of the sending, and the printing wheel of the receiving station, and as a necessary consequence, printing from the wheel while in rapid motion; but to this he had added two improvements of his own. One of these was a "corrector" by which the angular position of the type-wheel was automatically readjusted to correspond with the transmitter, at the printing of each letter, a feature essential to the completeness of the original conception; the other was an electro-magnetic speed-governor, of extraordinary simplicity and effectiveness. By a process of gradual evolution and adaptation, this instrument became the celebrated "Combination printer," an apparatus which from the threefold point of view of simplicity of construction, elegance of design, and effectiveness of performance, stands unrivaled in the annals of telegraphy. Even Mr. Phelps's subsequent invention—the motor printer—while perhaps justly regarded as one embodying a still higher degree of ingenuity, and even of distinct originality of conception, fails to impress one, in the same degree, with that indefinable something which characterizes the masterpiece, alike in art, literature or mechanism; the attainment of the most marvellous results by the simplest and apparently the most obvious expedients. As an example of consummate skill in mechanical design, this apparatus, in the opinion of the writer, stands unapproached in its department of technology.

In 1860, the American company removed the factory to Brooklyn, N. Y. In 1866, it passed into the hands of the Western Union Telegraph Co., and was subsequently removed to New York. Under the fostering care of president Orton, who was ever solicitous to effect improvements in the apparatus and methods of telegraphy, it grew into an extensive establishment. After the death of Mr. Orton, in 1878, a change of policy was inaugurated, which ultimately resulted in the sale of the factory to the Western Electric Manufacturing Co. During all these years, and it need scarcely be said, they were busy and fruitful ones, Mr. Phelps remained at his post as the superintendent and chief mechanician. Not one of all the diversified products demanded by the rapid progress and extension of the telegraph into new and varied fields of useness went forth which did not bear the unmistakable impress of his individuality. For however high Mr. Phelps may take rank

as an inventor, or as a skilful artisan, it was nevertheless as a designer that the intellectual side of his character found its freest scope and its most complete expression. While we think the Combination printer must be conceded to be his masterpiece, yet the stock-printer or "ticker" is a scarcely less striking example of his constructive genius. Originally planned for effective and hard service, its slowness of operation and barbaric clumsiness of design had been somewhat ameliorated by Edison, but it remained for Phelps to transform it into the thing of grace and beauty it is to-day, and at the same time to augment its working capacity many fold. The standard American Morse relay of the present day, is another simple but eminently characteristic example of his skill in the adaptation of novel, convenient and tasteful designs to old devices, which will be best appreciated by veteran telegraphers familiar with the "Clark" and "Cleveland" relays of a former day.

Mr. Phelps was somewhat reserved in manner and sparing of speech. Beneath his reticence there lay, nevertheless, a quiet kindliness and geniality, which will long be remembered by his associates and friends. A strong sense of humor, that unfailing friend of serious thinkers and workers, abode with him always.

Since Mr. Phelps retired from active business some four years since, it has been a source of regret to his many friends that impaired health has incapacitated him from enjoying fully the competence and leisure which he had so well earned, and which his passionate fondness for music and for the natural sciences, so eminently fitted him to appreciate. But although feeble in body, his mental faculties remained unclouded and his spirits buoyant to the last. He passed peacefully away, after a short illness, leaving to his family the precious inheritance of a good name, and the memory of a useful and high-minded life.

Mr. Phelps leaves a wife, a son, one of the editors of this journal, and a daughter. F. L. P.

OBSERVATIONS.

THE observer was asked a few days ago, "in what book could information be found regarding the *occultation* of hydrogen by palladium?"

. . .

THE Boston traveler has unearthed a saying of Emerson which is worth reproducing; here it is :—"Many years ago, before the civil war, Emerson fairly predicted the telephone. 'By new arts,' he wrote, 'the earth is subdued and we are on the brink of new wonders. The sun paints; *presently we shall organize the echo,* as we do now the shadow.'"

. . .

It is rather curious as one takes his walks abroad, to note the very wide-spread impression that the phonograph is an electrical device.

Its relationship to Mr. Edison, coupled with the identity of one of its functions with that of a telephone receiver seems to have given it a kind of brevet rank among electric appliances, which without doubt, will now be confirmed, since Mr. Edison has added an electromotor to make the wheels go round.

. . .

As to primary batteries, it appears that Great Britain is not to bear away all the honors. One need not go outside of New York to hear of a new primary battery—recently devised by Mr. Hussey. The published description which I have seen of this new battery is a meagre one, but coupled with the report of results, it reminds one of the famous request made every morning by the sister of the narrator of the Thousand and One Nights, the doomed sultana Scheherazade, "*Tell me sister, one of those tales you tell so well.*" The reader of the said published description and report of results is told ;—*Imprimis;* that the battery is open or closed.—

Item: that it is of the porous cup style, using *plain water,* which avoids the bother of placing salts in the jar.

Item: that there is no local action.

Item: that one cell placed on short circuit for 158 hours showed at the beginning of the test two and one-half amperes of current, and at the end three amperes.

Item: that it never polarizes, but uses up all the elements without waste.

Item: that it will maintain over one volt E. M. F. when on either open or closed circuit.

But the reader is not told what the original internal resistance of a battery set up with a porous cup, and "plain water" is; nor is it quite made clear how an E. M. F. of one volt can, with the same mild liquid, develop a current at the start, of two and one-half amperes, unlessthe rule $C \times R = E$ no longer holds good; since by a simple calculation we find the internal resistance under these conditions should be but .4 of an ohm; which of course is, under the circumstances, out of the question.

It is quite conceivable whatever the value of the current may be, that it should be greater at the close of the 158 hours of short circuiting than at the beginning, for supposing the positive element to be zinc, some soluble salt of that element will doubtless have formed *ad interim,* which will materially have lowered the internal resistance.

In the meantime, electricians may be excused for doubting the stated value of the original current; and most of us will continue to hold to the old fogy belief, that while zinc is employed for the positive element, economical considerations if no other, will preclude the successful competition of primary batteries with dynamos or secondary batteries in the fields which the latter now occupy; and it is hard to see a much brighter outlook if we substitute potassium, sodium, or magnesium. *Festina lente,* is a good motto for intending investors in primary battery stocks.

. . .

VOLUME xxii of the Encyclopædia Britannica has just been delivered to subscribers in the United States. One may venture the belief that it is to persons interested in the application of electricity to the useful arts, the most interesting volume yet issued; since it contains not only excellent articles upon the telegraph and the telephone, both written by Thomas Gray, B. Sc., F. R. S. E., but also a carefully written and valuable article on electrical traction by J. R. Ewing, Professor of Engineering, University College, Dundee.

The article on telegraphy gives a brief historical sketch of the art, a rapid resume of the principal methods, and devotes considerable space (as befits an author in a sea-girt isle) to submarine telegraphy. The space devoted to the telephone is exceptionally well filled, and it is hard to believe that it could have been done better, or more correctly. The principal credit is, in accordance with history and established fact, awarded to Professor A. Graham Bell; while Edison, Berliner, Gray and others are equitably and fairly dealt with. The author considers also the principal forms of carbon transmitters, the photophone and phonograph, and handles with great ability that utilization of the telephone which has proved to be the most important, viz.: the telephone exchange.

It is interesting to note that in the traction article, much dependence is placed by the author, in the American electrical journals, an involuntary tribute to their general reputation for giving exact and full information. Almost the only authorities referred to are the *Electrical Review*, ELECTRICAL ENGINEER and *Electrical World* of New York, and the "Electro-motor and its Applications," by Martin and Wetzler.

. . .

AT a recent meeting, at New York, of the executive committee of the National Electric Light Association, so it is recorded, the opinion was expressed by Dr. Moses, and others, that the "dead wires with which the air in our cities is filled" were responsible for the major part of the accidents to human life which have occurred. This opinion seems to have been concurred in by all hands, evidently being regarded as an inspiration. One does not wish to say that there are no dead wires, or that dead wires are not to be held partly responsible for some of the casualties. Yet it is painfully evident that many accidents have occurred, simply because the covering which has been chiefly employed for electric light wires is totally inadequate for its work, namely, the insulation of the wire. While it may be a correct statement that no durable first-class insulating covering

has as yet been devised, it would seem to be at least equally true, that much better coverings than those usually provided, are fully as durable, and that a dread of increased expense has made light supplying corporations woefully lax in this matter. Another and very obvious reply is that currents are not dangerous unless they are produced by a high E. M. F, and that if the number of arcs on a circuit are reduced materially the E. M. F. could also be reduced. Is it not, therefore, a duty, *if it be true that sufficient insulation cannot be provided*, to reduce the work per circuit, and consequently the E. M. F., and as a further consequence, the danger?

. . .

SOME time ago, we read a great deal, or at all events we had a great deal to read, about an electro-magnet of enormous size, made out of the muzzles of two cannon, and energized by the operation of a dynamo. The chronicled achievements of this magnet reminded one of the fabled loadstone mountains of Sinbad the sailor, which drew all the nails out of any unlucky vessel approaching within a league of its dreadful shore. It may be confessed that the writer of these lines said to himself "*cui bono?*" as he read of this wonderful magnet. It appears, however, that the idea has been adopted by the managers of rolling mills, and that by applying electro-magnets of moderate size to hydraulic cranes, ingots and other large masses of iron weighing as much as 800 pounds, are lifted with ease, and controlled simply by letting the current on and off. The observer has in former times worked in a rolling mill, and gladly welcomes this idea as being both feasible and useful.

. . .

ALL have heard of, and some of us have seen electric hair and flesh brushes, which are proved to be electric, by their ability to deflect a little compass needle, sold with them for the purpose. The unbeliever it is true, avers that there is nothing electric about these brushes, and that the deflection of the needle is caused by a magnet concealed in the back of the brush. Such is the incredulous nature of the unregenerate.

To these electrical marvels must now be added—"Electro-Magnetic Spectacles"—and as additional evidence of their surpassing value to the human race, they are patented (see U. S. Patent 381,260, April 17, 1888, to John Taylor Leighton, of Edinburgh). A pair of metal plates, one of which must be electro-positive to the other, are united by a coiled insulated wire twisted round the connecting piece and press upon the two sides of the bridge of the nose. The moisture of the flesh acts chemically upon these plates, thus forming a voltaic battery, the internal resistance of which is composed chiefly of the flesh and cartilage of the nose. The current so generated exercises a curative and strengthening influence on the eyes, temples, nerves, and muscles in connection therewith.

. . .

AKIN to the above, is the following, to which the "*Telegraphic Journal and Electrical Review*, London, kindly accords a free advertisement. One Mr. Pottage, of Edinburgh, sells to persons having more money and faith, than common sense, bottles of something which he calls "vegetable electricity" of various colors. The inventor of this remarkable article is a count—Count Mattei—and Pottage, who is a homeopathic chemist, is his agent. These colored electricities are warranted to be a cure for all diseases, totally eclipsing Holloway's Pills or Edison's Polyform.

Truly, as the only Barnum once said, "people love to be humbugged."

It may indeed be that Mr. Pottage is something of a Jacob, but where, in this electrical age, in America at least, shall Esaus be found simple enough to barter their birthright for such a mess of pottage.

POINTERS.

.... AN electric system is far less dependent upon its conductors than a cable railway is upon its rope.—*R. W. Blackwell.*

.... INACCURATE calibration is a much more common fault in the various instruments in market than bad design.—*J. Swinburne.*

.... IF you can calculate that you are selling your power at the same rates you are selling light, then if you can make 10 per cent. by selling current four hours per day, you can make 2½ times as much by selling current 10 hours per day.—*H. Mc I. Harding.*

.... WE have a patent system which is by far the best in the world. . . . The result of the patent law of this country has been the development of industries of such great magnitude that it has been copied in the laws of all nations.—*Wells W. Leggett.*

.... WE have proved beyond question that the alternating current can be put underground and can be put in lead covered cables without any danger of loss of current. If the direct wires cannot go underground, the alternating can.—*T. Carpenter Smith.*

.... IT is clear that high pressure, particularly if accompanied by rapid alternations, is not destined to assume any permanent position. It would be legislated out of existence in a very brief period even if it did not previously die a natural death. —*Edward H. Johnson.*

.... YOU must not try to get at the work which is being done on an alternating current circuit simply by multiplying the volts by the current; because there is a difference between the available current and that implied by the expressed electromotive force.—*Prof. George Forbes.*

.... I THINK if the gentlemen who are trying underground wires will simply shut their dynamos down regularly, by either short-circuiting the armature or shunting the field circuit, they will do away with a great deal of this punching holes in cables.—*T. Carpenter Smith.*

.... THE faults that occur in properly wired houses are few and far between. Out of those that do occur, 99 out of every 100 are due to switches, cut-outs, flexible cords and fittings, and therefore it is in simplifying and perfecting these that care should be taken.—*G. L. Addenbrooke.*

.... AS soon as the Americans get hold of anything that will work, they apply it. All the improvements in dynamos and in motors have practically been rejected on this side of the Atlantic. We seem to make the improvements for the Americans to make money out of.—*W. M. Mordey.*

.... THE most valuable men are the men of ideas; men who bring to light new facts in the material world; men who enlarge the boundaries of human knowledge, increase the resources of man and the means of enjoyment, and reduce the labor required to satisfy his wants.—*Chauncey Smith.*

.... I WELL remember when Faraday—who, I am sure, would be delighted, if he were living now, to witness the perfection which has been attained—saw the first dynamo at the premises of the Trinity House in 1856, he exclaimed "This was my child, but you have made a man of it.—*Sir James Douglas.*

.... ANYBODY who has been to America, and knows anything about American installations, will corroborate me in saying that the electric light machinery as made in the shop is perfection, but the putting up of it is such as would not pass muster in the worst of our English installations.—*R. E. Crompton.*

.... THE alternating current, while it is in mild doses of from 100 to 300 volts intensely more disagreeable than the direct current of the same voltage, when it comes to 1,000 volts or more, is very much less dangerous to life. I make this statement with the more confidence that I have tried them both.—*T. Carpenter Smith.*

.... IN an arc station you know about what your light is going to be. If you know your load is going to be 500 h. p., you can start your engine at pretty nearly its full load. There the big engine is undoubtedly the most economical. But in an incandescent station there is no regulation as to the amount of load.—*T. Carpenter Smith.*

.... AN immense amount of nonsense has been said and written on the subject of fire risks from electricity. These risks are so infinitesimal when installations are carried out by men who know their business, that it makes us electrical engineers lose patience when we hear the interminable discussions arising out of them.—*R. E. Crompton.*

.... MECHANICAL engineers are hardly aware of the enormous future before this new industry of electrical engineering. They hardly appreciate that it has got out of the region of small telegraphic instruments. The plant my firm are using for turning out modern electrical appliances is more like that used for planing armor plates.—*R. E. Crompton.*

.... THE best proof of economy in the use of converters is, that a test of the power expended in running a dynamo at its normal E. M. F., with its circuit closed through the primary coils of its full complement of converters, is the same as when the primary circuit is entirely open, within the ordinary limits of error of measurement.—*O. B. Shallenberger.*

ARTICLES.

WHAT IS THE SPECIFIC RESISTANCE OF COPPER?

BY GEORGE B. PRESCOTT, JR.

It is sometimes important to know the true resistance of pure copper, and every one who has had recourse to the text books for the purpose of ascertaining the specific value is aware that not only are the figures given in various arbitrary and inconvenient units, but has discovered, moreover, that if reduced to a common standard the values are discordant. In many cases no authority for the value used is mentioned, and in every instance where one is given, so far as my knowledge goes, it is attributed either to Matthiessen, or to Jenkin, who merely tabulated the results of Matthiessen's experiments.

Now, as Dr. Matthiessen conducted his experiments while a member of the committee of the British Association, which was appointed to determine upon a practical standard unit of resistance, the report of that committee[1] ought to give, authoritatively, the value of Matthiessen's determination. It seems, however, that Dr. Matthiessen devoted himself more particularly to ascertaining the permanency and relative resistances of the metals and alloys than to determining their specific resistance; so that, oddly enough, throughout the six reports made by the committee the only reference made to the absolute resistance of any of the metals or alloys is found in the third report, in a table showing the relative values of the proposed units of resistance. In this table the unit proposed by Matthiessen is *one English standard mile of pure annealed copper wire $\frac{1}{16}$ inch in diameter at* 15.5° *C., and having a resistance equal to* 13.59 B. A. *ohms.* This specific value for the resistance of copper has been extensively adopted, and is the basis of a table of the properties of copper wire by the writer, published in THE ELECTRICIAN AND ELECTRICAL ENGINEER four years ago, and also of the tables of the British Board of Trade and American standard gauges, which have since been promulgated.

In later tables more precise and scientific definitions of units and specific values have been employed, and specific resistance is now usually expressed in legal microhms between opposite faces of a centimeter cube or cubic inch of the material at 0° *C.* Happening to compare the tables of specific resistances which are published in the two recent and excellent text books by Professor Ayrton and by Professors Stewart and Gee, respectively, I observed that even they did not agree in their value for copper. Ayrton gives the specific resistance of pure annealed copper at 0° *C.* as

1.599 legal microhms per cubic centimeter =
.6292 " " " " inch.

While Stewart and Gee give the values as

1.616 legal microhms per cubic centimeter =
.6357 " " " " inch.

On looking further through a large number of electrical text books and pocket-books I found in the majority of cases that the specific resistance of pure copper was given as 9.718 B. A. ohms for a wire one foot long and one one-thousandth of an inch in diameter at 0° *C.*

In the report of the British Association Committee there is published, as an appendix, a series of "Cantor Lectures" on the subject of "Submarine Telegraphy," by Fleeming Jenkin. In the fourth lecture is a table of the specific resistances of metals and alloys calculated from Matthiessen's experiments, giving the values in foot-mils, foot-grains, etc., and this is the table which has been so extensively copied in most of the text books. Correcting Matthiessen's standard mile unit to the foot-mil dimensions as given by Jenkin gives

$$1 \text{ foot mil at } 15.5° \, C. = \frac{13.59 \times 62.5^2}{5280} = 10.054 \text{ B. A. ohms.}$$

1. Edited by Fleeming Jenkin, and published in 1873.

Using Dr. Matthiessen's formula to correct for the difference in temperature, viz.:

$$R = r\,(1 + at + bt^2).$$

In which R = the resistance at required temperature.
r = " " " given "
a = a constant number = + .003824.
b = a " " = + .00000126.
t = the number of degrees difference between the two temperatures, then

$$R = \frac{10.054}{1 + (.003824 \times 15.5) + (.00000126 \times 15.5^2)}$$
= 9.49 B. A. ohms at 0° *C.*

From which it follows that Jenkin's value is about 2.3 per cent. higher than Matthiessen's standard.

In order to fully understand the differences which exist in the published values of the specific resistance of pure annealed copper wire, it will be convenient to reduce the figures given above to the legal ohm and cubic inch units, assuming that one B. A unit = .9889 legal ohms. Then

$$\text{Jenkin's standard} = \frac{9.718 \times .9889 \times .7854}{12 \times 1000^2} = .629 \text{ legal mi-}$$

crohms per cubic inch, and Matthiessen's standard

$$= \frac{9.49 \times .9889 \times .7854}{12 \times 1000^2} = .6142 \text{ legal microhms per cubic}$$

inch.

It will thus be seen that Professor Ayrton and the majority of authors have accepted Jenkin's calculations, and that in standard wire tables Matthiessen's own unit has been taken as a basis; while Stewart and Gee, who state no authority, have a figure even higher than Jenkin's. Kohlrausch, I believe, quotes Matthiessen with even a lower figure than that given here, while intermediate values are to be found here and there.

The difference between the two references in the B. A. report will, probably, account for much of the confusion as to Matthiessen's value for the specific resistance of copper, particularly as both are attributed to him. I am inclined to think the lower figure nearer the true one, as it agrees more closely with the results of my own measurements.

SOME EXPERIMENTS ON A SPRAGUE TWO HORSE-POWER MOTOR.

BY FRANK P. COX, B. S.

(Johns Hopkins University.)

Leakage.—A single turn of wire was taken around one of the magnet limbs and a similar turn around the armature, which was turned until the plane of this coil was horizontal. A ballistic galvanometer was then connected with the turn around the field. Upon making the current around the field a throw of the needle is obtained which is proportional to the number of lines of force passing through this limb of the field. Twice this throw will, therefore, be proportional to the total intensity of the field. In a similar manner the number of lines of force passing through the armature is obtained. The ratio between these give the per cent. of the lines through the armature. The remaining lines representing the leakage. The throw of the galvanometer was noted upon making and also upon breaking the current through the field. Six such pairs of observations were taken and the mean used. The results follow:

Galvanometer connected to coil around the field.

Current made.	Current broken.	Mean.
304	314	309
302	312	307
303	340	321.5
332	339	335.5
333	336	334.5
331	336	333.5

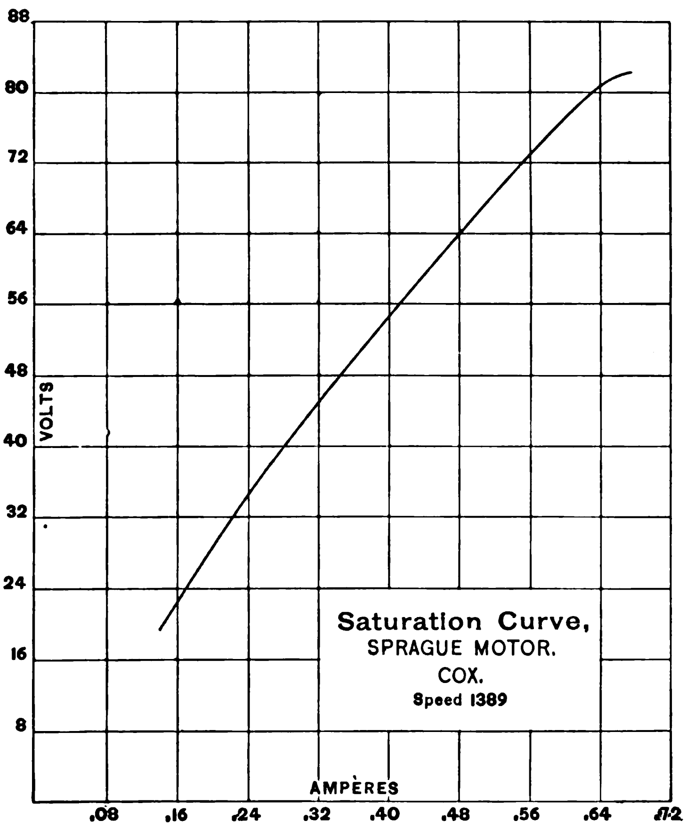
Mean for one magnet limb........................ 323.5
Mean for both magnet limbs.................... 647

Galvanometer connected to coil around armature.

Current made.	Current broken.	Mean.
366	376	371
364	374	369
363	373	368
362	370	366
359	369	364
360	370	365

Mean for armature.............................. 367
Per cent. of useful lines........................ 57%
Per cent. leakage.............................. 43%

Distribution of leak.—A coil of four turns was placed under a pole-piece. One-fourth the deflection obtained gives us the leak off the back of that pole-piece, and twice that the leak due to backs of pole-pieces. A turn of wire was taken around the bed plate and near the pole-pieces. Twice the



deflection obtained represents the leak due to the bed-plate. It should be remembered that the bed-plate and lower pole-piece are one casting.

Leakage from backs of pole-pieces.

Current Made.	Current broken.	One-fourth mean.
214	223	54.6
212	218	53.8
206	212	52.3
204	211	51.9
208	212	52.5

Mean for one pole-piece........................ 53
Mean for two pole-pieces........................ 106
Per cent. of leak................................ 16.4%

Leakage from bed-plate.

Current made.	Current broken.	Mean.
76	79	77.5
76	77	76.5
76	76	76
75	76	75.5
74	76	75
75	77	76

Mean for one end................................ 76.1
Mean for two ends.............................. 152.2
Per cent. of leak................................ 23.5%

Thus 39.9% leakage is accounted for from an observed leakage of 43%. The remainder may be accounted for by lines of force from one pole-piece to the other, external to the armature; from sides of pole-pieces, etc., etc.

Saturation of field.—The armature of the motor was disconnected and the current through the field changed after each of the readings following. The armature was rotated at a constant speed and the volts developed with different currents through the field were measured.

The potential of the exciting current was measured in place of the current itself, because a considerable change of potential corresponds to a slight change in the current. The resistance of the field was measured and found to be 167.5 ohms, from which was calculated the current.

Revolutions of armature 1389.

Volts of exciting current.	Amperes of exciting current.	Volts developed.
23.70	14	19.83
38.79	23	32.76
56.89	34	46.52
62.06	37	50.10
64.65	38	52.58
71.98	43	57.75
77.58	46	62.06
81.89	49	64.65
87.49	52	68.00
94.82	57	73.70
102.15	61	77.70
107.75	64	80.17
112.06	67	81.89
114.22	68	83.61

Saturation begins at 112.06 volts, or .67 amperes, so that in actual working the field is just below saturation.

A constant current of 15.92 amperes was then passed through the armature, the field being separately excited at 110 volts. The pulley on the armature shaft was bolted to the table on which the motor rested, and the leakage determined for different positions of the brushes which were shifted one commutator bar for each reading. A different ballistic galvanometer being used, it was necessary to repeat the readings for the field.

Field.

Made.	Broken.	Mean.
72	75	73.5
71	75	73
72	75	73.5
74	75	74.5
70	78	74
73	73	73

Mean for one limb............................ 73.6
Mean for two limbs............................ 147.2

Armature.

	Made.	Broken.	Mean.	Leak.
1st position	127	126	126.5	141
2d "	114	116	115	219
3d "	98	99	98.5	331
*4th "	80	83	81.5	446
5th "	64	66	65	558
6th "	52	53	52.5	644

Different currents were then passed through the armature with brushes in 4th position, and the leakage determined. The field was separately excited at 110 volts.

Armature.

Made.	Broken.	Mean.	Current.	Leak.
80	81	80.5	14.85	453
79	81	80	9.38	456
80	81	80.5	5.48	453
81	82	81.5	2.66	446
79	79	79	1.39	463

Efficiency.—Two efficiency tests were made; the first with practically the current and potential called for by the Co; the second with approximately 1 h. p. work being done.

* The 4th position is the one where the brushes rest when the motor is working.

Full load—Revolutions of motor, 1548.

EFFECT OF CHLORINE ON THE ELECTROMOTIVE FORCE OF A VOLTAIC COUPLE.[1]

BY DR. G. GORE, F. R. S.

IF the electromotive force of a small voltaic couple of unamalgamated magnesium and platinum in distilled water, is balanced through the coil of a moderately sensitive galvanometer of about 100 ohms resistance, by means of that of a small Daniell's cell plus that of a sufficient number of couples of iron and german silver of a suitable thermo-electric pile (see Proc. Birm. Philos. Soc. vol. iv. p. 130), the degree of potential being noted, and sufficiently minute quantities of very dilute chlorine water are then added in succession to the distilled water, the degree of electromotive force of the couple is not affected until a certain definite proportion of chlorine has been added; the potential then suddenly commences to increase, and continues to do so with each further addition within a certain limit. Instead of making the experiment by adding chlorine water, it may be made by gradually diluting a very weak aqueous solution of chlorine.

The minimum proportion of chlorine necessary to cause this sudden change of electromotive force is extremely small; in my experiments it has been one part in 17,000 million parts of water;[2] or less than one 7,000th part of that required to yield a barely perceptible opacity in 10 times the bulk of a solution of sal-ammoniac by means of nitrate of silver. The quantity of liquid required for acting upon the couple is small, and it would be easy to detect the effect of the above proportion or of less than one 10,000 millionth part of a grain of chlorine in one-tenth of a cubic centimeter of distilled water by this process. The same kind of action occurs with other electrolytes, but requires larger proportions of dissolved substance.

As the degree of sensitiveness of the method appears extreme, I add the following remarks. The original solution of washed chlorine in distilled water was prepared in a dark place by the usual method from hydrochloric acid and manganic oxide, and was kept in an opaque well-stoppered bottle in the dark. The strength of this liquid was found by means of volumetric analysis with a standard solution of argentic nitrate in the usual manner, the accuracy of the silver solution being proved by means of a known weight of pure chloride of sodium. The chlorine liquid contained 2.3 milligrammes or .03565 grain of chlorine per cubic centimeter, and was just about three-fourths saturated.

One-tenth of a cubic centimeter of this solution (No. 1) or .003565 grain of chlorine was added to 9.9 cc. of distilled water and mixed. One cubic centim. of this second liquid (No. 2) or .0003565 grain of chlorine was added to 99. cc. of water and mixed; the resulting liquid (No. 3) contained .000003565 grain of chlorine per cubic centim. To make the solutions (No. 4) for exciting the voltaic couple, successive portions of one-tenth or one-twentieth cc. of No. 3 liquid were added to 900 cubic centimeters of distilled water and mixed.

I have employed the foregoing method for examining the states and degrees of combination of dissolved substances in electrolytes, and am also investigating its various relations.

1. Read before the Royal Society, May 3, 1888.

2. As one part of chlorine in 17,612 million parts of water had no visible effect, and one in 17,000 million had a distinct effect, the influence of the difference, or of one part in 500,000 millions, has been detected.

PROTECTION OF THE HUMAN BODY FROM DANGEROUS CURRENTS.[1]

BY PATRICK B. DELANY.

SINCE the object of reading a paper before this society should be the enlightenment of members on the subject under consideration by the presentation of facts developed by experimentation or of theories supported by a reasonable amount of investigation, I must apologize for my delinquency in both respects, and trust to the kind indulgence of the society in making a few suggestions with a view of eliciting information and opinions from those whose experience and familiarity with the subject enables them to speak with authority.

I allude to what are considered dangerous currents and their effect on the human body. That there is danger in handling conductors conveying high tension currents must be generally admitted. The question, therefore, is, can fatal results from such currents be wholly or partially averted? All will agree that with proper care on the part of the companies and intelligent co-operation on the part of employés, but little would be heard of the danger of electric currents. But companies are economical and employés are careless. Familiarity with danger breeds contempt for it. This is exemplified almost daily in every department of industry. A new man in a powder mill will exercise the greatest care and observe all the rules of the establishment faithfully. In a few months the same man will smoke a pipe over an open powder keg.

Protection is necessary principally for those who through carelessness or ignorance fail to protect themselves. It has been claimed that there can be no such thing as an accident —that nature has none, and that all so-called accidents are simply the results of miscalculation, bad judgment or carelessness. But it must be remembered that the vigilance of the most alert will sometimes relax, and this to them is the moment of danger.

Realizing that something should be done to protect dynamo men and wire handlers from injury from powerful currents, I, a few years since, invented a device for shunting the vital parts of the body. Partly on account of a pressure of business in other branches of electricity, but principally owing to a hesitancy in bringing out a device about the efficacy of which there seemed to be some doubt, its introduction to scientific criticism was delayed until a few weeks ago. As the references made to the question in the electrical papers have failed to elicit an expression of opinion satisfactory to any degree, it has been deemed advisable to bring the subject before this meeting.

The question to be determined is, to what extent a wire of practically no resistance, extending from one wrist to the other and bound around the wrists in numerous convolutions, so as to make good but not uncomfortable contact, will protect the vital parts of the body from fatal injury when it is placed in the path of a dangerous current through contact at the hands. It is claimed by some that the current having once entered the muscles, veins and tissue at the hands, will not leave the arms at the wrists and follow the shorter path of the wire, but will confine its course to the arms and body alone. The other opinion is that the greater portion of the current received at the hands will leave the arms at the wrists and follow the wire. The problem seems a difficult one to solve. So much depends on the condition of the person at the time of receiving a shock, a

1. Read before the American Institute of Electrical Engineers, May 16, 1888.

large number of tests would be necessary to arrive at results which would afford a safe basis for calculation. A few years ago Dr. Stone, connected with one of the London hospitals, made a series of interesting experiments upon patients afflicted with various ailments, with a view of determining whether or not fluctuation in their physical condition affected the electrical conductivity or resistance of their bodies. The results proved, according to my recollection, that great changes took place in the electrical resistance of the patients experimented upon from day to day, and that there was a direct influence manifested by the rise and fall of different diseases upon the electrical conductivity of the body as a whole or in part. An account of Dr. Stone's experiments was published in *Nature* at the time. But while the experiments were most valuable for the purpose for which they were intended, they throw but little light on the subject of dangerous currents and protection from fatal injury.

Last September, there was published in the *Electrical Review*, of London, a paper on "Shocks from Alternating Currents," by Mr. G. L. Addenbrooke, who for some time previous had charge of the Grosvenor Gallery installation, where a primary current of 2,500 volts was constantly employed. While no one had ever come in contact with both mains at once, the writer stated that even if such an accident had happened he was "by no means prepared to assert that the result would undoubtedly be fatal." "Indeed," says he, "I rather incline to the opinion that if the subject of the shock were healthy, and the circumstances under which he received it were favorable, the chances are he would survive."

I cannot make out what Mr. Addenbrooke means by receiving 2,500 volts under favorable circumstances. It seems to me, if they are received at all, the circumstance could not be other than unfavorable. Mr. Addenbrooke himself received a severe shock, and as he speaks from experience, I quote his account of how it affected him: "The primary effect of the passage of the current through the body is, of course, to contract the muscles. The amount and persistence of this contraction depend on the quantity of the current flowing, or, as it is usually designated, *the intensity* of the shock, and varies from a simple twitching of the limbs to complete and intense contraction or rigor of apparently every muscle in the body. In this latter case, the current completely supersedes the action of the mind over everything capable of contraction or movement. Consciousness, however, is apparently rarely, if ever, lost, though the subject may be entirely unable to make any motion, cry out, or do anything to help himself. If aid is not near, such a state may be maintained for some time. On release from such a position by extraneous or natural causes, the subject is usually dazed, but if at all unconscious, soon recovers completely and experiences no further functional disturbance than the debility and nervousness naturally following such a severe strain on the system." While admitting that fatal shocks are possible, this gentleman gives it as his opinion that "if the shock is not sufficient to cause instantaneous collapse, apparently the body can bear the strain of the continued passage of the current for some time, and that death is caused by paralysis of the involuntary muscles controlling the heart and lungs, and that the preliminary stages of total collapse are analogous to what occurs when drowning." Referring to the local action of the current on the body where it enters and leaves, this writer also says: "If the contact is good, that is, if it consists of a good area, say of over a couple of square inches of a fairly moist skin pressed with moderate firmness against a metallic body or other good conductor, no visible injury may result. For instance, a man will often get burnt about the hands, but his feet, by which the current leaves, will be unaffected, or only slightly reddened or inflamed. Burning of the hands or other parts of the body will occur when there is imperfect contact of the body with the conductor, coming in contact with a bad or semi-conductor, such as a dirty or carbonized surface. The burning is caused by the absolute setting up of an arc."

It seems to me this gentleman's views, based, as we are led to believe, on actual experience, are somewhat paradoxical. And surely numerous cases of deaths from currents recently, disprove many of Mr. Addenbrooke's deductions. True, nothing short of death is made public, so that there is but little information to go upon relating to the instances which must be of frequent occurrence where men are *almost* killed by electric shocks. In all cases that have come to light, whether simply injuries or cases of death, the parts of the body coming in contact with the current have been badly burned. The unfortunate "trouble hunter," who lost his life a few days since, was not only burned at the hands but at the knees. In cases where the shock is not instantly fatal, may it not be that the burning of the flesh at the points of contact is so great as to destroy to a considerable extent the conducting substance in contact with the wire, and thereby cause a fall in the current passing through the body? It is certainly owing to the fact of the body being a very poor conductor that harm is done. If it offered no resistance there would be no realization that a current was passing through it. An arc would be created at the point of contact, provided the contact was *imperfect*, but the body itself would be uninjured. It seems to me that the human body must be viewed as any other semi-conductor, with the exception perhaps of susceptibility to greater change under the continued action of a current owing to the fluids which it contains. It is owing to its resistance that a carbon filament becomes incandescent.

The carbon rod of an electric lamp is not consumed except at the point where the arc is formed by the resistance of attenuated particles under combustion. Any conducting substance placed in the path of more current than it is capable of conveying must be heated, consumed or decomposed, according to its nature and in proportion to the discrepancy between the conducting capacity of the conductor and the sum of the current.

Now if we liken the human body from hand to hand to a canvas hose or tube filled with water and which allows a certain quantity of moisture to ooze through the surface, corresponding to the moisture of the skin, and if this be inserted in a circuit, connection being made at the extreme ends, corresponding to the hands, and a shunt wire of minimum resistance be wound around the tube two or three inches from the ends, corresponding say to the wrists, we can, perhaps, more understandingly speculate on the action of a dangerous current on the human body, contact being made at the hands and the shunt wire encircling the wrists. It should be borne in mind that the contact between the shunt wire and wrists is much better than the contact at the hands, since the wrists are more tender than the hands. Now referring to the tube and assuming that the contacts at the ends have improved by reason of the current eating its way into the water, does it not follow that the current instead of following the entire length of the tube of water, offering, say 30 times the resistance of the two or three inches of water from the end of the tube to the shunt wire, and several thousand times the resistance of the shunt wire itself, will, to a great extent, pass from the tube to the shunt wire and in its passage *improve* the contact at that point as it did at the ends in entering the tube? I have often noticed that upon receiving a shock of 150 to 250 volts profuse perspiration instantly followed. This would greatly improve the contact at the wrists above the normal, so that it would seem impossible that the current should confine itself to the fluids and muscles of the body in preference to the wire when separated from the wire only by thin tender skin filled with moisture.

In considering the danger point of currents it seems reasonable to recognize the same law, or rather recognize the absence of any law, governing other destructive agencies. Let it be concussion, strain, asphyxia, poison, or other enemy of endurance, there are hardly two cases alike. One man may emerge with but slight injury from a cause which to another man would be death. Why should it not be so in the matter of electric shock? Death, of course, must be

the consequence of a certain degree of cause. If 2,000 volts are necessary to kill in any instance, one volt less would avert death, while shunting 100 or 500 volts would leave a proportionate margin of safety. Fatal results through the medium of electricity do not come by jumps any more than by any other force or element of destruction. There is in this subtle agency, as in all others, a last straw which breaks the camel's back—a last volt which does the final harm. Hence the importance of protecting, as far as possible, those exposed to this danger.

Regarding the immediate cause of death or the effect of currents on the substances of the body, we must look to the medical men for light. Probably all subjected to shock might not be similarly affected. In one case it might be the heart, in another the brain, and in others the lungs that might be injured. Why not have a thorough investigation of this subject, and then perhaps wire handlers may be subjected to an examination before they are allowed to engage in such work, just as men are examined for various other duties.

There seems to be so little known about these matters, I shall feel gratified if this paper serves as even a feeble incitement to discussion and investigation, as I can conceive of no subject offering a more humane incentive.

ON COMPENSATED RESISTANCE STANDARDS.[1]

BY EDWARD L. NICHOLS.

The electrician has few more troublesome corrections to make in the course of his measurements than those arising from the influence of temperature upon resistance. Were the heating of wires due solely to changes in the surrounding air, the matter would not be a serious one. Such changes could be reduced to a minimum by devices well known in the art of physical measurements, unavoidable changes could be determined by the aid of the thermometer, the temperature coefficient for the various elements of the circuit could be ascertained and proper corrections applied.

Since, however, heat is developed in every circuit in amount measured by the product of the current and the E. M. F. between the terminals, the temperature of a wire through which a current flows is always higher than the surrounding atmosphere. In the case of heavy currents, the temperature of the wire may be very high indeed. The difficulty of applying corrections for temperature is such as to lead to frequent rejection of methods which would otherwise be of great convenience, and might lead to results of the highest accuracy.

The discovery of a substance, the resistance of which would not change perceptibly under the influence of heat, would, it goes without saying, be of great value. Unfortunately all known metals are influenced in the same sense, nor has any alloy been found which is devoid of a temperature coefficient. The exhaustive investigations of the British Association Committee in this field are too well known to need recapitulation, and while some alloys have been recently produced which are much better than anything that committee was able to discover, even these forfeit much of their usefulness on account of their low conductivity.

One substance only, among the solid conductors of electricity, seems to offer a solution of the difficulty. Carbon, as has been shown by Matthiessen,[2] Siemens, and many later observers, differs from the metals in showing a decrease of resistance with rise of temperature. The amount of this change, which differs widely in the case of the various artificial carbons, is given in the following table :

TABLE I.

INFLUENCE OF TEMPERATURE UPON THE RESISTANCE OF VARIOUS VARIETIES OF CARBON.

Observer.	Variety of carbon.	Temperature interval.	Mean coefficient per deg.
Werner Siemens (*Wiedemann's Annalen*, 10, p. 560).	Gas carbon.........	0 to 200°	.000345

The temperature coefficient, while varying widely for different carbons, is very nearly constant for a range of more than 100 degrees, in the case of any given specimen. It seemed probable, in view of this fact, that a conductor might be constructed by combining carbon with a metal in proper proportions, in which the influence of temperature upon the carbon and the metal respectively would precisely counterbalance each other, thus securing to the combination a constant resistance throughout a considerable range of temperature.

The calculation of the proportions necessary to this result, in the case of carbon, the coefficient of which has been determined, and a given metal, copper for example, is very simple.

Assuming that the combination would be subject to the law of parallel circuits, no alloy being formed, and no chemical combination between the parts taking place, we have for the total resistance R:

$$R = \frac{R_m R_c}{R_m + R_c},$$

where R_m is the resistance of the metal and R_c the resistance of the carbon.

The equation of condition, for complete compensation will be

$$\frac{R_m' R_c'}{R_m' + R_c'} = \frac{R_m'' R_c''}{R_m'' + R_c''}$$

where R_m' R_c' are the resistances of the components and R_m'' R_c'', the corresponding resistances at any other temperature within the limits of temperature for which compensation exists.

Now the variation of the resistance of a metal with the temperature may be expressed by an equation of the form :

$$R_m'' = R_m' (1 + at \pm bt^2),$$

where a and b are coefficients to be determined by experiment.

In the case of carbon, the coefficient a will have a negative value, and the equation will take the following form :

$$R_c'' = R_c' (1 - at \pm bt^2).$$

Between 0° and 100° the value of b in the case both of

1. Read before the American Institute of Electrical Engineers, May 16, 1888
2. Matthiessen, *Poggendorff's Annalen*, 115, p. 353.

copper and carbon is very small. A recent determination of the coefficients for copper, made in the Physical Laboratory of Cornell University, yielded the equation :

$$R_m'' = R_m' (1 + .00380\, t + .00000047\, t^2).$$

The experiments, which covered a range of 100°, are in close agreement with the results published by Matthiessen.

In the above equation, for $t = 100°$, we have $bt^2 = .0047$. If we neglect the coefficient b and adopt for a the mean coefficient between 0° and 100°, we may write the equation in the simpler form,

$$R_m'' = R_m' (1 + .003847\, t),$$

which will give results agreeing with the complete form at 0° and 100°, and will have a maximum error, at 50°, of .0008.

In the case of carbon the coefficient b may also be neglected without appreciable error.

A Carré pencil, measured by another member of the same laboratory, gave as mean coefficient between 0° and 100°, the value .000235.

We may, therefore, write the equation for this variety of carbon, as follows :

$$R_c'' = R_c' (1 - .000235\, t).$$

The relative influence of heat upon the resistance of copper and carbon is shown graphically in figure 1, which

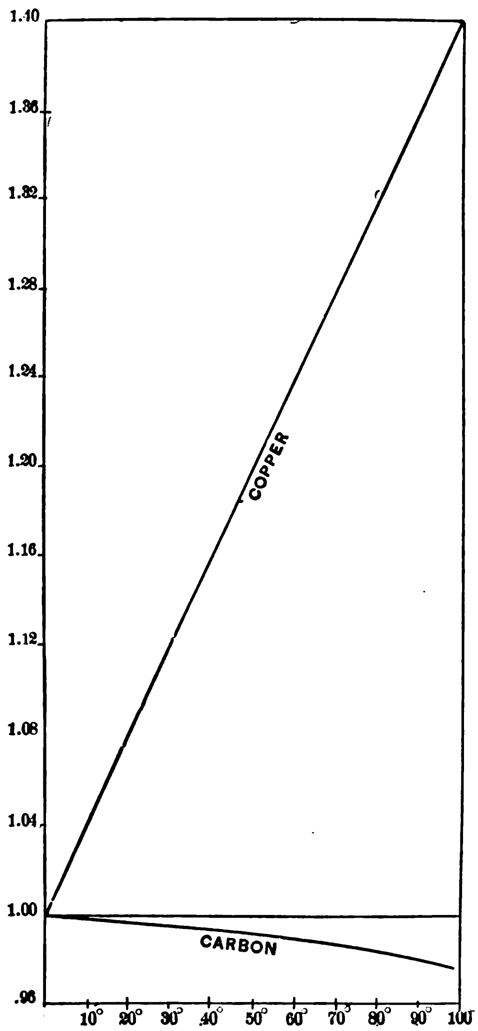

Fig. 1.

diagram will also serve to indicate the nearly constant value of the temperature coefficient of those substances.

In combining copper and carbon in such proportions that the resulting resistance shall be independent of the temperature, the following equation of condition must be satisfied.

$$\frac{R_m'\, R_c'}{R_m' + R_c'} = \frac{R_m''\, R_c''}{R_m'' + R_c''}.$$

This equation will be satisfied only for a range of temperatures throughout, which $b^2\, t$ is negligible, in the case of both substances.

For such a range of temperatures we have, however, as already indicated,

$$R_m'' = R_m' (1 + a_m\, t)$$
$$R_c'' = R_c' (1 - a_c\, t);$$

where a_c and a_m are the coefficients for carbon and copper respectively.

Within such limits

$$\frac{R_m'\, R_c'}{R_m' + R_c'} = \frac{R_m' (1 + a_m\, t)\, R_c' (1 - a_c t)}{R_m' (1 + a_m\, t) + R_c' (1 - a_c\, t)};$$

which is readily reducible to the form,

$$R_m' \left(\frac{a_c\, t}{1 - a_c\, t} \right) = R_c' \left(\frac{a_m\, t}{1 + a_m\, t} \right)$$

Using the coefficients already determined for copper and the variety of carbon in question, namely :

$$a_m = .003847.$$
$$a_c = .000235.$$

We find,

$$R_m = 11.544\, R_c.$$

In a word, we must use, for every ohm of carbon, 11.544 ohms of copper in order to secure complete compensation for temperature.

Three methods of combining the copper and carbon in such a compensated resistance have occurred to me as likely to give a good result. The first method consists in wrapping an insulated wire, of the necessary resistance, around the carbon and soldering the ends to the terminals of the bar, previously copper-plated for that purpose. The second method consists in mixing the proper amount of copper in a finely divided state with the paste of which the rod is to be made, and then molding and baking the carbon in the usual manner.

In the third method, which is the only one which I have as yet put to actual trial, the carbon, having been tested and its temperature coefficient determined, is electro-plated with copper. Experience showed that the film of copper necessary to compensation was so thin as to be scarcely adherent. The following process was therefore submitted for that of coating the entire surface. A Carré carbon 2.95 mm. in diameter was copper-plated for about 5 mm. at each end. The ends were then amalgamated and placed in mercury cups, which formed the terminals of a Wheatstone bridge. The resistance of the rod having been measured, and its mean coefficient between 20° and 100° having been determined, the length necessary for a compensated resistance of one legal ohm was calculated. The rod was then cut to the proper length, allowing 5 mm. at each end for terminals. The ends were heavily plated, and were inserted into the ends of copper rods, which were carefully soldered to the carbon. The rod was then given a coat of shellac, and, when dry, a strip of the varnish was removed with a sharp knife. The strip laid bare was parallel to the axis of the rod, and extended from terminal to terminal. Its width was about 1 mm. The rod was then submerged in a plating bath of sulphate of copper.

In this way a film of copper was deposited upon the exposed portion, which combined the required electrical resistance, 11.544 ohms, with sufficient thickness to render it tough and adherent. It was found that one gravity cell, acting through 50 ohms, would deposit the requisite amount of copper for a one ohm bar, in about 10 minutes. When the above process had been carefully carried out, the rod was found to have very nearly the proper total resistance and to be nearly perfect in the matter of compensation. If the rod was over-compensated, copper was removed by careful scraping. If it was under-compensated, carbon was

removed by the same process. These final adjustments were continued until the rod showed no perceptible change of resistance when heated to 100°. When the compensation was regarded as satisfactory, the adjustment of total resistance was made by removing the copper-plating of the terminals, or extending the same by renewed plating. This, if carefully done, would bring the rod to the proper resistance without impairing the compensation. The rod, after adjustment, was well varnished, and was inserted in a glass tube of about 7 mm. internal diameter. This tube was provided with brass caps, through which the copper terminals projected to a distance of about 5 cm. These, after being securely riveted to the brass caps, were bent through an angle of 90°. When thus mounted the resistance-rod presented the appearance indicated in figure 2.

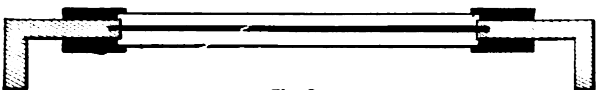

Fig. 2.

In the manner just described, I succeeded after a few trials in producing a resistance rod upon which the influence of the temperature between 18° and 100° was entirely imperceptible. The object being to test the method of compensation, and not to produce a standard ohm, the adjustment for final resistance was not carried out.

The resistance of the compensated rod, after being mounted, is shown in the following table :

TABLE II.

RESISTANCE OF A COMPENSATED RESISTANCE ROD AT VARIOUS TEMPERATURES ; MEASUREMENTS BY MR. GEO. D. SHEPARDSON.

Temperatures.	Resistance in B. A. ohms.
105° C.	1.0300
98°	1.0300
87°	1.0305
35°	1.0305
22.5°	1.0295
19°	1.0300

For the purpose of this measurement, the rod was immersed in an oil bath and heated to more than 100°. The readings were taken while the bath was cooling. They indicate a practically perfect compensation throughout the range of temperature given in the table.

If such a compensated resistance-rod be quickly heated or cooled, the copper will change more promptly than the carbon and the balance will be temporarily destroyed. While in process of heating from without, the resistance will increase somewhat, and while cooling by radiation the reversed effect will be noticeable.

In rods not mounted in glass and unprotected by a coating of varnish these variations are very marked. Table iii. contains a set of readings made upon such a rod. The rod was rapidly heated and cooled, and was measured several times during the rise and fall of temperature. The compensation was nearly complete, the mean coefficient between 20° and 100 being less than .00002, but the rod in question exhibited temporary variations when suddenly heated and cooled, amounting to more than one per cent.

TABLE III.

TEMPORARY VARIATIONS OF A COMPENSATED ROD SUBJECTED TO SUDDEN CHANGES OF TEMPERATURE.

Temp.	Resistance.	Temp.	Resistance.
25°	1.0050	78°	1.0030
(Gas ignited.)		(Gas extinguished.)	
37°	1.0072	78°	0.9965
45°	1.0074	74°	0.9960
55°	1.0070	63°	0 9975
62°	1.0040	40°	1.0030
68°	1.0040	25°	1.0050
70°	1.0040		

Compensated resistance-bars, such as have been described in this paper, are of course limited in their application to uses in which carbon conductors are admissible. For standards of resistance I think they will be found especially valuable. The convenience of having a comparison resistance the value of which can be determined once for all, and which can then be used with confidence, without regard to its temperature, even in circuits which would heat our ordinary standard coils and modify their resistances to a notable extent, will be appreciated by all. In the construction of low-resistance shunts, also, the possibility of obtaining a conductor which will remain unchanged at all ordinary temperatures, whether heated from without or by the passage of the current, will permit us to adopt with confidence the use of high resistance galvanometers, with low resistance shunts, for the measurement of large currents, even where the highest accuracy is necessary.

To those who, in the course of their electrical work, have to cope daily with the question of the influence of temperature upon resistance, numerous other applications of compensated resistance-rods will suggest themselves.

THE POSSIBILITIES AND LIMITATIONS OF CHEMICAL GENERATORS OF ELECTRICITY.[1]

BY FRANCIS B. CROCKER.

ELECTRO-CHEMISTRY seems less generally and less clearly understood than any other branch of electricity of equal importance. The facts concerning the dynamo, motor, telegraph and telephone are widely and definitely known ; but there are ideas, statements and claims in regard to batteries which are further from the truth, more prevalent and go longer without being contradicted than any other collection of errors that I can call to mind.

Primary batteries have not received the attention in this country that they have abroad, particularly in England, where the successful or unsuccessful attempts to float a new primary battery company is a matter of almost weekly occurrence. Nevertheless the subject is a sufficiently important one, and the false ideas of which I have spoken have spread so far beyond the quacks, to whom such ideas are usually confined, that the subject deserves more study than it usually receives, particularly from the scientific standpoint.

Electromotive force.—The electromotive force which a given battery or combination of materials will develop is the first and most important question in electro-chemistry. Of course, the best and surest way to arrive at this E. M. F. is to determine it by actual experiment with a voltmeter, or, still better, by comparison with a standard cell. There are, however, many times when the materials or instruments are not at hand, and a calculation or predetermination of the E. M. F. is very convenient.

The formula for calculating the E. M. F. is obtained by assuming that the electrical energy of the given chemical combination is equal to the heat energy which the same combination is capable of producing, or $E\ C = 4.16\ C\,a\,H$, that is, volts multiplied by coulombs is equal to the coulombs multiplied by the electro-chemical equivalent, *i. e.*, the weight of material required per coulomb and that by the heat produced by one gramme of the material. The electrical equivalent of heat 4.16 is introduced to reduce both members of the equation to an electrical basis. Canceling the C in both members, we have $E = 4.16\ aH$, in which E is the E. M. F. in volts, a is the electro-chemical equivalent (grammes per coulomb), and H is the number of heat units (gramme-degrees Cent.) produced per gramme of material by the given chemical combination. The values of a and H are given for most materials in electrical and chemical books of reference, and the calculation is a very simple one; nevertheless this formula and the principle involved in it are not generally understood, and are very seldom used. The equation deduced above is that ordinarily given, but what I have found to be a more convenient form of it is obtained by assuming that $E = I$, giving a its

1. Read before the American Institute of Electrical Engineers, May 16, 1888.

value for hydrogen (.00001035). Solving with respect to H we have $H = 23300$, which means that 23300 is the number of heat units per equivalent corresponding to one volt, and all that is necessary to find the volts of any given chemical combination is to divide the number of heat units per equivalent (which is the form they are almost always given in) by 23300 and the quotient is the E. M. F. in volts. For example, to obtain the E. M. F. which zinc and free chlorine will develop, divide 48600 (which is the number of heat units produced by the combination of one equivalent of zinc with one of chlorine as given by Thomsen) by 23300, and the result 2.09 is certainly very close to 2.11, the actual value obtained by experiment. In the same way the E. M. F. of other combinations of materials may be predetermined, but it should always be borne in mind that the heat of combination corresponding to one *equivalent* of the material should be taken and not necessarily that corresponding to one atom; as for example in the case of zinc, the heat per atom (65 grammes) is 97,200 which has to be divided by 2 to reduce it to one equivalent that. There has been no warping or coaxing of the figures to secure uniformity. The results are given just as they came. If figures were picked out from the different observations, it would be possible to obtain almost perfect agreement between the calculated and determined, as one may see by looking over the tables.

In regard to the experimental results as given in tables A, B and C, I may state that all the metals and salts used were chemically pure, with the exception of the metals magnesium and aluminium, and these were of a very good quality. Pure carbon plates were used for the negative plate, but platinum was also tried and gave substantially the same results. The E. M. F. was measured by a Thompson reflecting galvanometer (by Elliott), using two independent standard Daniell cells. One fact which strikes one in looking over the tables A, B and C, is that the E. M. F. is not very greatly affected by the solution; a certain metal gives about the same result in one chloride as in another, and the same is true of the bromides and iodides. In table E, I have given the E. M. F. obtained by substituting different metals for the zinc in a Daniell's cell, but these results being from only one series of observations are probably not so reliable as those in the preceding tables.

because zinc is a dyad and takes two atoms of chlorine, which is a monad. In the case of monad metals, like sodium, potassium and silver, the figures may be taken just as they are given in the tables. Mistakes very frequently arise in this way; in fact I do not think I ever saw a table of electro chemical equivalents in which this point was correctly introduced in every case.

In order to test the practicability and accuracy of calculating E. M. F. as well as to obtain reliable results and full data for their own value, I determined the E. M. F. given by thirteen of the most important metals in combination with free chlorine, bromide and iodine, and the results are given in tables A, B and C respectively. In table D I have averaged these results and placed them side by side with the results obtained by calculation. The agreement between the two sets of figures is not perfect by any means, but when it is remembered how the E. M. F. of a cell will change one or two-tenths of a volt on apparently the slightest provocation, I think the figures are strikingly close, more so than I expected to find them. In more than half of the cases the difference is less than one-tenth of a volt, and the average difference is only slightly more than

In the remaining table I have collected in condensed form the principle facts in regard to batteries in which zinc is used as the electro-positive material with the most important electro-negative or depolarizing materials. The facts in regard to metallic zinc, which hold good in all cases in which it is used (no matter what the other material is), are given on a horizontal line with zinc. Below this the facts in regard to each particular combination are given opposite the depolarizer. For example, the data of a zinc and chlorine battery are given on a horizontal line with chlorine, of a zinc and nitric acid (Bunsen) battery on a line with nitric acid.

For convenience the table is divided into two parts; the left-hand side contains the purely scientific data, and the right-hand portion contains the practical facts.

In the first column of the first part is given the chemical symbols reduced to a common basis, any one of the expressions being chemically equivalent to any other. For example, one-half atom of zinc ($\frac{1}{2}$Zn) requires one atom of

chlorine (Cl), or one-half atom of oxygen ($\frac{1}{2}O$), or one-third molecule of chromic acid ($\frac{1}{3}Cr_2O_3$), or one-sixth of the mixture of one molecule of potassium bichromate and seven molecules of sulphuric acid ($\frac{1}{6}[K_2Cr_2O_7 + 7H_2SO_4]$), and so on.

In the second column is given the chemical equivalents which are simply the proportions by weight required of the different materials. That is, when we use 32.5 grammes of zinc (hydrogen being assumed as one gramme), we require 35.5 grammes of chlorine, or 33.4 grammes of chromic acid, and so on.

The third column contains the electro-chemical equivalents, which are really exactly the same and directly proportional to the combining weights in the previous column, parts of sulphuric acid, which is about the ordinary strong bichromate solution for porous cell batteries. Of course the water required for the solution is not considered here or in any of the other figures of the tables, because it costs nothing and serves merely as a medium of electrical action; but if the total weight of solution is desired, the weight of water must be added.

The weight of the different materials consumed per ampere hour is given in the next column. These figures are obtained directly from the electro-chemical equivalents in the third column by dividing by 125; in fact, they are simply the electro-chemical equivalents in pounds per ampere hour.

It should always be carefully noted that the weight

TABLE A.

E. M. F. produced by different Metals in Combinations with Free Chlorine in Solutions of —.

	Magnesium Chloride.		Zinc Chloride.	Zinc Chloride.	Zinc Chloride.	Hydro-Chloric Acid.	Common. Salt.	Average.
Magnesium	2.83	2.65	2.65			3.2–3.15	2.85	3.1
Zinc	2		2.20	2.13	2.11	2.20	2.18	2.11
Cadmium			1.94		1.86	1.98	1.93	1.9

Bismuth			1.29	1.25	1.20	1.27	1.19	1.21

but are reduced to an electric basis of so many milligrammes per coulomb. To convert these figures into grammes per ampere hour simply multiply by 3.6.

In the first column of the second part of the table is given the E. M. F. of each combination, all of which with the exception of oxygen, sulphur and water are determined by experiment, most of them being well known and accepted values. In the case of oxygen, sulphur and water the E. M. F. is calculated as explained above and is consumed per ampere hour is that required in *each cell* in *series*, whereas in the case of horse-power hours the weight given in the table is the total weight used, no matter how many cells there are or how they are arranged.

In the next to the last column is given the wholesale cost per pound of the different materials. These prices are of course very difficult to fix, because they depend upon the market and vary greatly upon the quantities bought; but the prices I have here are very low, and ordinary con-

TABLE B.

Bismuth	.92	.9	.96	.88	.92	.92

merely given for comparison. No actual battery corresponding to these materials exists.

In the second column, on the right-hand side, is given the number of pounds of zinc required per horse-power hour in the case of each combination. For example, a zinc and copper sulphate (Daniell) battery requires 1.86 pounds of zinc per horse-power hour of electrical energy produced.

In the next column I give the weight of depolarizer required per horse-power hour in the case of each combination. For example, a battery requires 5.05 pounds of the mixture of three parts of potassium bichromate; and seven sumers would have to pay twice as much in most cases; they give, however, some idea of costs.

In the last column I have given the cost of both materials, zinc and depolarizer, added together. I have not here considered the values of the products, because it is very difficult to estimate the cost of collecting and utilizing residues. In the case of silver chloride the silver resulting from the action would, of course, be worth a large portion of the cost of the original chloride.

One of the interesting points which this table shows is the total weight required per horse-power hour. For example, .95 pound of zinc and 1.04 pounds of chlorine,

making a total of almost exactly two pounds, would produce one horse-power of current for one hour if all of the chemical energy could be converted into electric energy.

This brings up the question of how large a percentage of the chemical energy can be utilized, or, in other words, the efficiency of chemical generators. This efficiency is higher, I think, than it is generally supposed to be. I have no exact figures upon this point, but I have tested several times the weight of zinc consumed compared with the theoretical amount, and I have found that even in a plunge battery, where the bichromate solution was directly in contact with the zinc and the opportunity for local action was a maximum, that the zinc efficiency was as high as 75 per cent., and in one case 80 per cent. In a porous cell battery with amalgamated zinc, where there was little or no cause for local action, I believe the zinc efficiency would be as high as 90 per cent., and I should not be surprised to find it as high as 96 or 97 per cent.

The efficiency of the depolarizer is generally lower than that of the zinc, because there is generally a good deal of chemical energy left in the solution after it is too weak for satisfactory work. The efficiency of the bichromate solution in the plunge battery I have just referred to was only about 45 per cent. of the total theoretical power. But this is very low, because the solution has to be weak in acid on account of being used in contact with the zinc. In the case of a copper sulphate battery, where the crystals of sulphate are often almost entirely used up, I think the efficiency would be as high as 80 or 90 per cent. The efficiency I speak of here is simply the *chemical* efficiency in the battery; the fall of potential in the battery due to its internal resistance compared to the external is another loss which has to be added to the chemical loss in determining the total efficiency.

The possibilities of chemical generators are, therefore, almost infinite, since it requires theoretically a total of only two pounds of zinc and chlorine, and two pounds of zinc and chromic acid per horse-power hour, and since the efficiency of batteries can easily be made as high as 75 per cent. it follows that less than three pounds of material is actually required per horse-power hour; but unfortunately the water for the solution, the containing vessel, electrodes, etc., are so heavy that the total weight is very many times greater. The possible and the actual battery are thus very far apart. If we use metals of higher chemical affinity and E. M. F. than zinc the theoretical weight of material required is even less; only one pound total of chlorine and magnesium are required per horse-power hour; with metallic sodium and free chlorine having a calculated E. M. F. of 4 volts it would only take about .8 pound per horse-power.

The easiest and best solution of the problem, however, does not seem to be the use of more powerful metals than zinc. The latter is powerful enough; it only takes, as we have seen, about one pound of it per horse-power hour with nitric acid, chromic acid or bichromate solution, and less than two pounds with copper sulphate. The opportunity for improvement seems to lie more in the direction of perfecting the general form of batteries. The *apparatus* is at fault, not the *chemical action*. Moreover, zinc is about as high on the electro-positive scale as it is safe to go so long as water is present. Even in the case of zinc its affinity for oxygen is greater than that of hydrogen; it is therefore only by tolerance, so to speak, that zinc remains passive in the presence of water. If it is not properly amalgamated, or if the solution is too strong, local action does occur. If, in place of zinc, we use any more electro-positive metal these troubles are aggravated; with magnesium, for example, there are only very few solutions in which it will stand without great local action. Metals of still higher power, such as sodium, cannot be used at all in presence of water. Jablochkoff has, I believe, made cells in which sodium is used with damp cloth, but this can hardly be considered as water.

The proper way to use metals of great chemical energy would seem to be with liquids which do not contain any oxygen, but unfortunately such solutions are not generally good conductors. Another possible plan is to employ a fused electrolyte, but this involves the serious difficulty of maintaining it in the fused state.

So far as I can see, zinc is a very satisfactory positive material for batteries. After all it is cheaper than any other metal except iron. It is a sufficiently good conductor, and less dirty and liable to corrosion than almost any other metal; it is also, as I have just shown, about as high on the electro-positive list as it is safe to go.

The electro-negative materials on the other hand leave far more to be desired. They are generally expensive, very troublesome to handle, and introduce that quality of simple dirtiness, to which no other name can be applied, and which is really the most serious objection to batteries. The electro-negatives will, however, do the work, and as we have seen it actually requires very little weight to give a great deal of power, if the materials could only be used in a more perfect manner than at present. That seems to be the thing to hope for. Another serious difficulty with batteries is their high internal resistance. A dynamo can easily be made to give 100 volts with a thousandth or a few ten thousandths of an ohm internal resistance, hence their great output; but a primary battery capable of giving 100 volts with only one thousand ohm internal resistance would probably fill this house.

In this connection it will be interesting to consider how many cells of ordinary gravity battery are required to give one horse-power of current. Each cell will give one volt and not more than half an ampere under normal conditions, hence each cell furnishes half a watt or about 1,500 cells to the horse-power. These cells would, however, give that power for a long time. But the fact remains that this very large number is required to produce the power which a dynamo not much larger than one's hat will generate.

In conclusion, I would say that I am by no means a skeptic in regard to chemical generators of electricity; the possibilities are very, very great, as I have shown. But these possibilities do not seem to have been brought to reality in a very perfect manner as yet. But batteries, even in the imperfect state in which they exist to-day, have their useful and legitimate function. A Leclanché cell is exceedingly well adapted to ringing electric bells intermittently and to telephone work, and gravity batteries have long done good service for telegraphic purposes.

But when it comes to developing any considerable amount of actual power, then the limitations become apparent. When we remember that battery electricity will certainly cost in practice 50 cents per horse-power hour, since the materials alone cost 25 cents, and that dynamo electricity only costs 2 cents per horse-power hour, the claims of some primary battery electric lighting promoters show up in their true light. As a luxury, of course, it makes very little difference what it costs, but even then people soon tire of paying very high prices for that kind of a luxury. For small electric lighting and small power in special cases batteries are useful, particularly where no other source of current is available. A physician or dentist to whom a horse-power hour may be worth hundreds of dollars could almost afford to use a chloride of silver battery and throw away the silver.

A NEW SYSTEM OF ALTERNATE CURRENT MOTORS AND TRANSFORMERS.[1]

BY NIKOLA TESLA.

In the presence of the existing diversity of opinion regarding the relative merits of the alternate and continuous current systems, great importance is attached to the question whether alternate currents can be successfully utilized in the operation of motors. The transformers, with their numerous advantages, have afforded us a relatively perfect system of distribution, and although, as in all branches of the art, many improvements are desirable, comparatively little remains to be done in this direction. The transmission of power, on the contrary, has been almost entirely confined to the use of continuous currents, and notwithstanding that many efforts have been made to utilize alternate currents for this purpose, they have, up to the present, at least as far as known, failed to give the result desired. Of the various motors adapted to be used on alternate current circuits the following have been mentioned: 1. A series motor with subdivided field. 2. An alternate current generator having its field excited by continuous currents. 3. Elihu Thomson's motor. 4. A combined alternate and continuous current motor. Two more motors of this kind have suggested themselves to me. 1. A motor with one of its circuits in series with a transformer and the other in the secondary of the transformer. 2. A motor having its armature circuit connected to the generator and the field coils closed upon themselves. These, however, I mention only incidentally.

The subject which I now have the pleasure of bringing to your notice is a novel system of electric distribution and transmission of power by means of alternate currents, affording peculiar advantages, particularly in the way of motors, which I am confident will at once establish the superior adaptability of these currents to the transmission of power and will show that many results heretofore unattainable can be reached by their use; results which are very much desired in the practical operation of such systems and which cannot be accomplished by means of continuous currents.

Before going into a detailed description of this system, I think it necessary to make a few remarks with reference to certain conditions existing in continuous current generators and motors, which, although generally known, are frequently disregarded.

In our dynamo machines, it is well known, we generate alternate currents which we direct by means of a commutator, a complicated device and, it may be justly said, the source of most of the troubles experienced in the operation of the machines. Now, the currents so directed cannot be utilized in the motor, but they must—again by means of a similar unreliable device—be reconverted into their original state of alternate currents. The function of the commutator is entirely external, and in no way does it affect the internal working of the machines. In reality, therefore, all machines are alternate current machines, the

1. Read before the American Institute of Electrical Engineers, May 16, 1888.

currents appearing as continuous only in the external circuit during their transit from generator to motor. In view simply of this fact, alternate currents would commend themselves as a more direct application of electrical energy, and the employment of continuous currents would only be justified if we had dynamos which would primarily generate, and motors which would be directly actuated by such currents.

But the operation of the commutator on a motor is twofold; firstly, it reverses the currents through the motor, and secondly, it effects, automatically, a progressive shifting of the poles of one of its magnetic constituents. Assuming, therefore, that both of the useless operations in the system, that is to say, the directing of the alternate currents on the generator and reversing the direct currents on the motor, be eliminated, it would still be necessary, in order to cause a rotation of the motor, to produce a progressive shifting of the poles of one of its elements, and

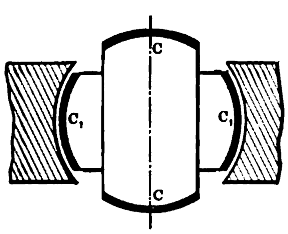

Fig. 1.

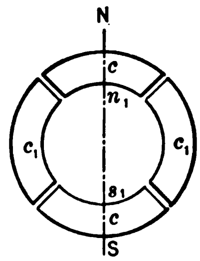

Fig. 1a.

the question presented itself,—How to perform this operation by the direct action of alternate currents? I will now proceed to show how this result was accomplished.

In the first experiment a drum-armature was provided with two coils at right angles to each other, and the ends of these coils were connected to two pairs of insulated contact-rings as usual. A ring was then made of thin insulated plates of sheet-iron and wound with four coils, each two opposite coils being connected together so as to produce free poles on diametrically opposite sides of the ring. The remaining free ends of the coils were then connected to the contact-rings of the generator armature so as to form two independent circuits, as indicated in figure 9.

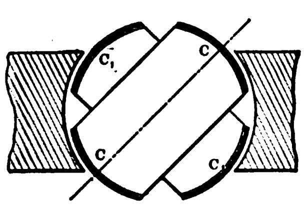

Fig. 2.

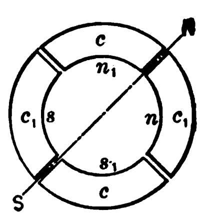

Fig. 2a.

It may now be seen what results were secured in this combination, and with this view I would refer to the diagrams, figures 1 to 8*a*. The field of the generator being independently excited, the rotation of the armature sets up currents in the coils C C, varying in strength and direction in the well-known manner. In the position shown in figure 1 the current in coil C is nil while coil C_1 is traversed by its maximum current, and the connections may be such that the ring is magnetized by the coils c_1 c_1 as indicated by the letters N S in figure 1*a*, the magnetizing effect of the coils *c c* being nil, since these coils are included in the circuit of coil C.

In figure 2 the armature coils are shown in a more advanced position, one-eighth of one revolution being completed. Figure 2*a* illustrates the corresponding magnetic condition of the ring. At this moment the coil C_1 generates a current of the same direction as previously, but weaker, producing the poles n_1 s_1 upon the ring; the coil C also generates a current of the same direction, and the connections may be such that the coils *c c* produce the poles *n s*, as shown in figure 2*a*. The resulting polarity is indicated by the letters N S, and it will be observed that the poles of the ring have been shifted one-eighth of the periphery of the same.

In figure 3 the armature has completed one-quarter of

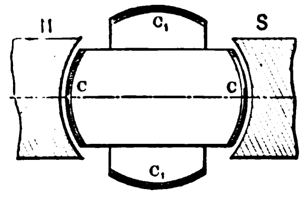

Fig. 3.

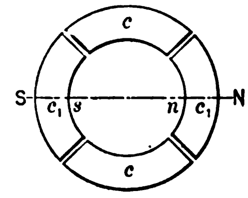

Fig. 3a.

one revolution. In this phase the current in coil C is maximum, and of such direction as to produce the poles N S in figure 3*a*, whereas the current in coil C_1 is nil, this coil being at its neutral position. The poles N S in figure 3*a* are thus shifted one-quarter of the circumference of the ring.

Figure 4 shows the coils C C in a still more advanced position, the armature having completed three-eighths of one revolution. At that moment the coil C still generates a current of the same direction as before, but of less strength, producing the comparatively weaker poles *n s* in figure 4*a*. The current in the coil C_1 is of the same strength, but of opposite direction. Its effect is, therefore, to produce upon the ring the poles n_1 and s_1 as indicated, and a polarity, N

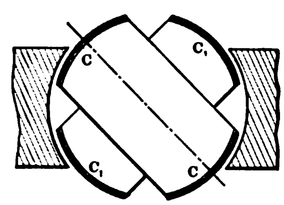

Fig. 4.

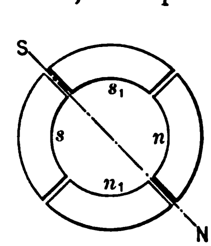

Fig. 4 a.

S, results, the poles now being shifted three-eighths of the periphery of the ring.

In figure 5 one-half of one revolution of the armature is completed, and the resulting magnetic condition of the ring is indicated in figure 5*a*. Now, the current in coil C is nil, while the coil C_1 yields its maximum current, which is of the same direction as previously; the magnetizing effect is, therefore, due to the coils c_1 c_1 alone, and, referring to figure 5*a*, it will be observed that the poles N S are shifted one-half of the circumference of the ring. During the next half revolution the operations are repeated, as represented in the figures 6 to 8*a*.

A reference to the diagrams will make it clear that during one revolution of the armature the poles of the ring

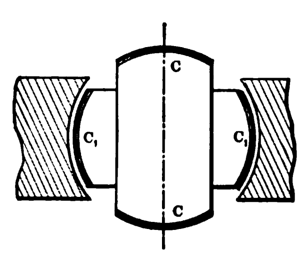

Fig. 5.

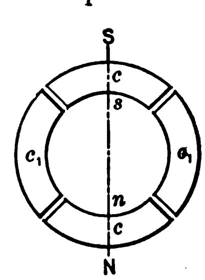

Fig. 5 a.

are shifted once around its periphery, and each revolution producing like effects, a rapid whirling of the poles in harmony with the rotation of the armature is the result. If the connections of either one of the circuits in the ring are reversed, the shifting of the poles is made to progress in the opposite direction, but the operation is identically

the same. Instead of using four wires, with like result, three wires may be used, one forming a common return for both circuits.

This rotation or whirling of the poles manifests itself in a series of curious phenomena. If a delicately pivoted disc of steel or other magnetic metal is approached to the ring it is set in rapid rotation, the direction of rotation varying with the position of the disc. For instance, noting the direction outside of the ring it will be found that inside the ring it turns in an opposite direction, while it is unaffected if placed in a position symmetrical to the ring. This is easily explained. Each time that a pole approaches it induces an opposite pole in the nearest point on the disc, and an attraction is produced upon that point; owing to this, as the pole is shifted further away from the disc a tangential pull is exerted upon the same, and the action being constantly repeated, a more or less rapid rotation of the disc is the result. As the pull is exerted mainly upon

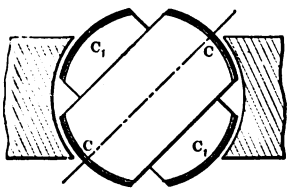

Fig. 6.

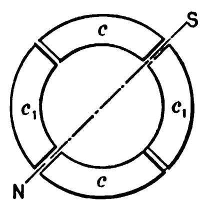

Fig. 6 a.

that part which is nearest to the ring, the rotation outside and inside, or right and left, respectively, is in opposite directions, figure 9. When placed symmetrically to the ring, the pull on opposite sides of the disc being equal, no rotation results. The action is based on the magnetic inertia of the iron; for this reason a disc of hard steel is much more affected than a disc of soft iron, the latter being capable of very rapid variations of magnetism. Such a disc has proved to be a very useful instrument in all these investigations, as it has enabled me to detect any irregularity in the action. A curious effect is also produced upon iron filings. By placing some upon a paper and holding them externally quite close to the ring they are set in a vibrating motion, remaining in the same place, although the paper may be moved back and forth; but in lifting the paper to a certain height which seems to be dependent on the intensity of the poles and the speed of rotation, they are thrown away in a direction always opposite to the supposed movement of the poles. If a paper with filings is put flat upon the ring and the current turned on suddenly, the existence of a magnetic whirl may be easily observed.

To demonstrate the complete analogy between the ring and a revolving magnet, a strongly energized electro-magnet was rotated by mechanical power, and phenomena identical in every particular to those mentioned above were observed.

Obviously, the rotation of the poles produces corresponding inductive effects and may be utilized to generate cur-

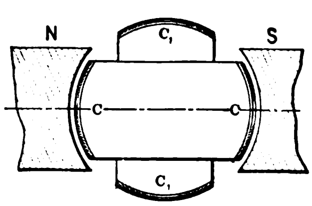

Fig. 7.

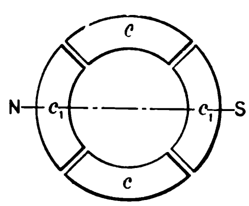

Fig. 7 a.

rents in a closed conductor placed within the influence of the poles. For this purpose it is convenient to wind a ring with two sets of superimposed coils forming respectively the primary and secondary circuits, as shown in figure 10. In order to secure the most economical results the magnetic circuit should be completely closed, and with this object in view the construction may be modified at will.

The inductive effect exerted upon the secondary coils will be mainly due to the shifting or movement of the magnetic action; but there may also be currents set up in

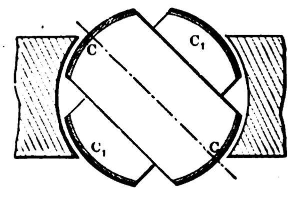

Fig. 8.

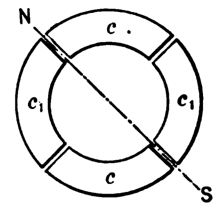

Fig. 8 a.

the circuits in consequence of the variations in the intensity of the poles. However, by properly designing the generator and determining the magnetizing effect of the primary coils, the latter element may be made to disappear. The intensity of the poles being maintained constant, the action of the apparatus will be perfect, and the same result will be secured as though the shifting were effected by means of a commutator with an infinite number of bars. In such case the theoretical relation between the energizing effect of each set of primary coils and their resultant magnetizing effect may be expressed by the equation of a circle having its centre coinciding with that of an orthogonal system of axes, and in which the radius represents the resultant and the co-ordinates both of its components. These are then respectively the sine and cosine of the angle α between the radius and one of the axes (OX). Referring to figure 11, we have $r^2 = x^2 + y^2$; where $x = r \cos \alpha$, and $y = r \sin \alpha$.

Assuming the magnetizing effect of each set of coils in the transformer to be proportional to the current—which

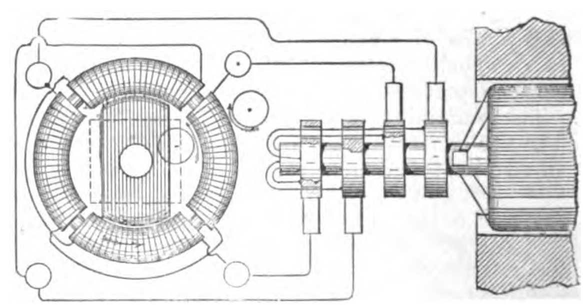

Fig. 9.

may be admitted for weak degrees of magnetization—then $x = Kc$ and $y = Kc^1$, where K is a constant and c and c^1 the current in both sets of coils respectively. Supposing, further, the field of the generator to be uniform, we have for constant speed $c^1 = K^1 \sin \alpha$ and $c = K^1 \sin (90° + \alpha) = K^1 \cos \alpha$, where K^1 is a constant. See figure 12.

Therefore,
$$x = Kc = KK^1 \cos \alpha;$$
$$y = Kc^1 = KK^1 \sin \alpha, \text{ and}$$
$$KK^1 = r.$$

That is, for a uniform field the disposition of the two coils at right angles will secure the theoretical result, and the intensity of the shifting poles will be constant. But from $r^2 = x^2 + y^2$ it follows that for $y = 0$, $r = x$; it follows that the joint magnetizing effect of both sets of coils should be equal to the effect of one set when at its maximum action. In transformers and in a certain class of motors the fluctuation of the poles is not of great importance, but in another class of these motors it is desirable to obtain the theoretical result.

In applying this principle to the construction of motors, two typical forms of motor have been developed. First, a form having a comparatively small rotary effort at the start, but maintaining a perfectly uniform speed at all

loads, which motor has been termed synchronous. Second, a form possessing a great rotary effort at the start, the speed being dependent on the load.

These motors may be operated in three different ways: 1. By the alternate currents of the source only. 2. By a combined action of these and of induced currents. 3. By the joint action of alternate and continuous currents.

The simplest form of a synchronous motor is obtained by winding a laminated ring provided with pole projections with four coils, and connecting the same in the manner before indicated. An iron disc having a segment cut away on each side may be used as an armature. Such a motor is shown in figure 9. The disc being arranged to rotate freely within the ring in close proximity to the projections, it is evident that as the poles are shifted it will, owing to its tendency to place itself in such a position as to embrace the greatest number of the lines of force, closely follow the movement of the poles, and its motion will be synchronous with that of the armature of the generator; that is, in the peculiar disposition shown in figure 9, in which the armature produces by one revolution two current impulses in each of the circuits. It is evident that if, by one revolution of the armature, a greater number of impulses is produced, the speed of the motor will be correspondingly increased. Considering that the attraction exerted upon the disc is greatest when the same is in close proximity to the

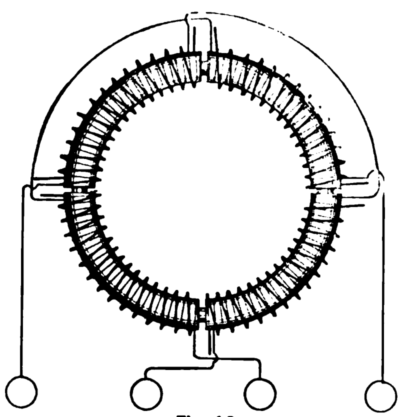

Fig. 10.

poles, it follows that such a motor will maintain exactly the same speed at all loads within the limits of its capacity.

To facilitate the starting, the disc may be provided with a coil closed upon itself. The advantage secured by such a coil is evident. On the start the currents set up in the coil strongly energize the disc and increase the attraction exerted upon the same by the ring, and currents being generated in the coil as long as the speed of the armature is inferior to that of the poles, considerable work may be performed by such a motor even if the speed be below normal. The intensity of the poles being constant, no currents will be generated in the coil when the motor is turning at its normal speed.

Instead of closing the coil upon itself, its ends may be connected to two insulated sliding rings, and a continuous current supplied to these from a suitable generator. The proper way to start such a motor is to close the coil upon itself until the normal speed is reached, or nearly so, and then turn on the continuous current. If the disc be very strongly energized by a continuous current the motor may not be able to start, but if it be weakly energized, or generally so that the magnetizing effect of the ring is preponderating it will start and reach the normal speed. Such a motor will maintain absolutely the same speed at all loads. It has also been found that if the motive power of the generator is not excessive, by checking the motor the speed of the generator is diminished in synchronism with that of the motor. It is characteristic of this form of motor that it cannot be reversed by reversing the continuous current through the coil.

The synchronism of these motors may be demonstrated experimentally in a variety of ways. For this purpose it is best to employ a motor consisting of a stationary field magnet and an armature arranged to rotate within the same, as indicated in figure 13. In this case the shifting of the poles of the armature produces a rotation of the latter in the opposite direction. It results therefrom that when the normal speed is reached, the poles of the armature assume fixed positions relatively to the field magnet and the same

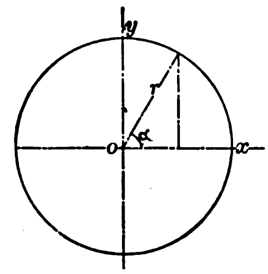

Fig. 11.

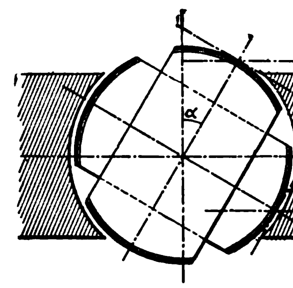

Fig. 12.

is magnetized by induction, exhibiting a distinct pole on each of the pole-pieces. If a piece of soft iron is approached to the field magnet it will at the start be attracted with a rapid vibrating motion produced by the reversals of polarity of the magnet, but as the speed of the armature increases the vibrations become less and less frequent and finally entirely cease. Then the iron is weakly but permanently attracted, showing that the synchronism is reached and the field magnet energized by induction.

The disc may also be used for the experiment. If held quite close to the armature it will turn as long as the speed of rotation of the poles exceeds that of the armature; but when the normal speed is reached, or very nearly so, it ceases to rotate and is permanently attracted.

A crude but illustrative experiment is made with an incandescent lamp. Placing the lamp in circuit with the continuous current generator, and in series with the magnet coil, rapid fluctuations are observed in the light in consequence of the induced currents set up in the coil at the start; the speed increasing, the fluctuations occur at longer intervals, until they entirely disappear, showing that the motor has attained its normal speed.

A telephone receiver affords a most sensitive instrument; when connected to any circuit in the motor the synchronism may be easily detected on the disappearance of the induced currents.

In motors of the synchronous type it is desirable to

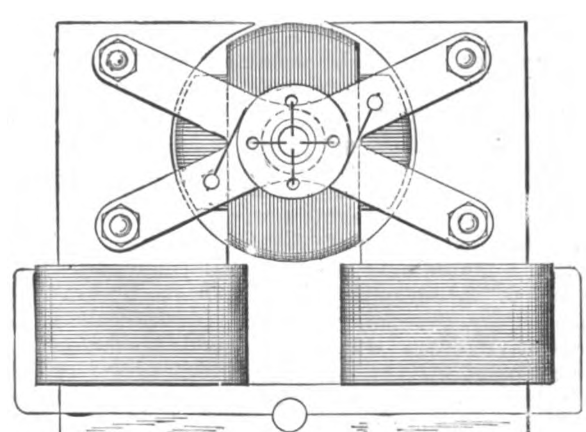

Fig. 13.

maintain the quantity of the shifting magnetism constant, especially if the magnets are not properly subdivided.

To obtain a rotary effort in these motors was the subject of long thought. In order to secure this result it was necessary to make such a disposition that while the poles of one element of the motor are shifted by the alternate

currents of the source, the poles produced upon the other element should always be maintained in the proper relation to the former, irrespective of the speed of the motor. Such a condition exists in a continuous current motor; but in a synchronous motor, such as described, this condition is fulfilled only when the speed is normal.

The object has been attained by placing within the ring a properly subdivided cylindrical iron core wound with several independent coils closed upon themselves. Two coils at right angles as in figure 14, are sufficient, but a greater number may be advantageously employed. It results from this disposition that when the poles of the ring are shifted, currents are generated in the closed armature coils. These currents are the most intense at or near the points of the greatest density of the lines of force, and their effect is to produce poles upon the armature at right angles to those of the ring, at least theoretically so; and since this action is entirely independent of the speed—that is, as far as the location of the poles is concerned—a continuous pull is exerted upon the periphery of the armature. In many respects these motors are similar to the continuous current motors. If load is put on, the speed, and also the resistance of the motor, is diminished and more current is made to pass through the energizing coils, thus increasing the effort. Upon the load being taken off, the counter-electromotive force increases and less current passes through the primary or energizing coils. Without any load the speed is very nearly equal to that of the shifting poles of the field magnet.

It will be found that the rotary effort in these motors fully equals that of the continuous current motors. The effort seems to be greatest when both armature and field magnet are without any projections; but as in such dispositions the field cannot be very concentrated, probably the best results will be obtained by leaving pole projections on one of the elements only. Generally, it may be stated that the projections diminish the torque and produce a tendency to synchronism.

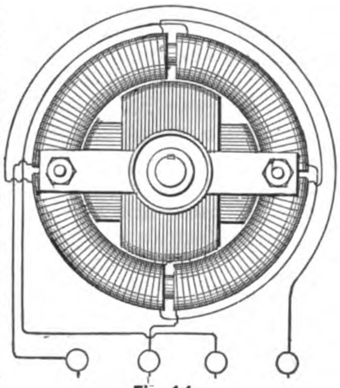

Fig. 14.

A characteristic feature of motors of this kind is their capacity of being very rapidly reversed. This follows from the peculiar action of the motor. Suppose the armature to be rotating and the direction of rotation of the poles to be reversed. The apparatus then represents a dynamo machine, the power to drive this machine being the momentum stored up in the armature and its speed being the sum of the speeds of the armature and the poles. If we now consider that the power to drive such a dynamo would be very nearly proportional to the third power of the speed, for this reason alone the armature should be quickly reversed. But simultaneously with the reversal another element is brought into action, namely, as the movement of the poles with respect to the armature is reversed, the motor acts like a transformer in which the resistance of the secondary circuit would be abnormally diminished by producing in this circuit an additional electromotive force. Owing to these causes the reversal is instantaneous.

If it is desirable to secure a constant speed, and at the same time a certain effort at the start, this result may be easily attained in a variety of ways. For instance, two armatures, one for torque and the other for synchronism, may be fastened on the same shaft, and any desired preponderance may be given to either one, or an armature may be wound for rotary effort, but a more or less pronounced tendency to synchronism may be given to it by properly constructing the iron core; and in many other ways.

As a means of obtaining the required phase of the currents in both the circuits, the disposition of the two coils at right angles is the simplest, securing the most uniform action; but the phase may be obtained in many other ways, varying with the machine employed. Any of the dynamos at present in use may be easily adapted for this

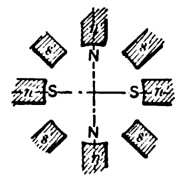

Fig. 15.

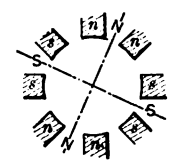

Fig. 16.

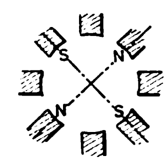

Fig. 17.

purpose by making connections to proper points of the generating coils. In closed circuit armatures, such as used in the continuous current systems, it is best to make four derivations from equi-distant points or bars of the commutator, and to connect the same to four insulated sliding rings on the shaft. In this case each of the motor circuits is connected to two diametrically opposite bars of the commutator. In such a disposition the motor may also be operated at half the potential and on the three-wire plan, by connecting the motor circuits in the proper order to three of the contact rings.

In multipolar dynamo machines, such as used in the converter systems, the phase is conveniently obtained by winding upon the armature two series of coils in such a manner that while the coils of one set or series are at their maximum production of current, the coils of the other will be at their neutral position, or nearly so, whereby both sets of coils may be subjected simultaneously or successively to the inducing action of the field magnets.

Generally the circuits in the motor will be similarly disposed, and various arrangements may be made to fulfill the requirements; but the simplest and most practicable is to arrange primary circuits on stationary parts of the motor, thereby obviating, at least in certain forms, the employment of sliding contacts. In such a case the magnet coils are connected alternately in both the circuits; that is, 1, 3, 5......in one, and 2, 4, 6......in the other, and the coils of each set of series may be connected all in the same manner, or alternately in opposition; in the latter case a motor

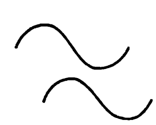

Fig. 18.

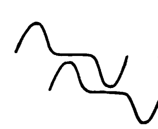

Fig. 19.

Fig. 20.

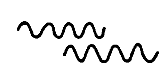

Fig. 21.

with half the number of poles will result, and its action will be correspondingly modified. The figures 15, 16 and 17, show three different phases, the magnet coils in each circuit being connected alternately in opposition. In this case there will be always four poles, as in figures 15 and 17, four pole projections will be neutral, and in figure 16 two adjacent pole projections will have the same polarity. If the coils are connected in the same manner there will be eight alternating poles, as indicated by the letters *n′ s′* in figure 15.

The employment of multipolar motors secures in this system an advantage much desired and unattainable in the continuous current system, and that is, that a motor may be made to run exactly at a predetermined speed irrespective of imperfections in construction, of the load, and, within certain limits, of electromotive force and current strength.

In a general distribution system of this kind the following plan should be adopted. At the central station of supply a generator should be provided having a consider-

able number of poles. The motors operated from this generator should be of the synchronous type, but possessing sufficient rotary effort to insure their starting. With the observance of proper rules of construction it may be admitted that the speed of each motor will be in some inverse proportion to its size, and the number of poles should be chosen accordingly. Still exceptional demands may modify this rule. In view of this, it will be advantageous to provide each motor with a greater number of pole projections or coils, the number being preferably a multiple of two and three. By this means, by simply changing the connections of the coils, the motor may be adapted to any probable demands.

If the number of the poles in the motor is even, the action will be harmonious and the proper result will be obtained; if this is not the case the best plan to be followed is to make a motor with a double number of poles and connect the same in the manner before indicated, so that half the number of poles result. Suppose, for instance, that the generator has twelve poles, and it would be desired to obtain a speed equal to $\frac{12}{7}$ of the speed of the generator. This would require a motor with seven pole projections or magnets, and such a motor could not be properly connected in the circuits unless fourteen armature coils would be provided, which would necessitate the employment of sliding contacts. To avoid this the motor should be provided with fourteen magnets and seven connected in each circuit, the magnets in each circuit alternating among themselves. The armature should have fourteen closed coils. The action of the motor will not be quite as perfect as in the case of an even number of poles, but the drawback will not be of a serious nature.

However, the disadvantages resulting from this unsymmetrical form will be reduced in the same proportion as the number of the poles is augmented.

If the generator has, say, n, and the motor n_1 poles, the speed of the motor will be equal to that of the generator multiplied by $\frac{n}{n_1}$.

The speed of the motor will generally be dependent on the number of the poles, but there may be exceptions to this rule. The speed may be modified by the phase of the currents in the circuits or by the character of the current impulses or by intervals between each or between groups of impulses. Some of the possible cases are indicated in the diagrams, figures 18, 19, 20 and 21, which are self-explanatory. Figure 18 represents the condition generally existing, and which secures the best result. In such a case, if the typical form of motor illustrated in figure 9 is employed, one complete wave in each circuit will produce one revolution of the motor. In figure 19 the same result will be effected by one wave in each circuit, the impulses being successive; in figure 20 by four, and in figure 21 by eight waves.

By such means any desired speed may be attained; that is, at least within the limits of practical demands. This system possesses this advantage besides others, resulting from simplicity. At full loads the motors show an efficiency fully equal to that of the continuous current motors. The transformers present an additional advantage in their capability of operating motors. They are capable of similar modifications in construction, and will facilitate the introduction of motors and their adaptation to practical demands. Their efficiency should be higher than that of the present transformers, and I base my assertion on the following:—

In a transformer as constructed at present we produce the currents in the secondary circuit by varying the strength of the primary or exciting currents. If we admit proportionality with respect to the iron core the inductive effect exerted upon the secondary coil will be proportional to the numerical sum of the variations in the strength of the exciting current per unit of time; whence it follows that for a given variation any prolongation of the primary current will result in a proportional loss. In order to obtain rapid variations in the strength of the current, essential to efficient induction, a great number of undulations are employed. From this practice various disadvantages result. These are, increased cost and diminished efficiency of the generator, more waste of energy in heating the cores, and also diminished output of the transformer, since the core is not properly utilized, the reversals being too rapid. The inductive effect is also very small in certain phases, as will be apparent from a graphic representation, and there may be periods of inaction, if there are intervals between the succeeding current impulses or waves. In producing a shifting of the poles in the transformer, and thereby inducing currents, the induction is of the ideal character, being always maintained at its maximum action. It is also reasonable to assume that by a shifting of the poles less energy will be wasted than by reversals.

THE PATENT COURT AND UNIFORMITY IN PATENT PRACTICE[1].

BY GEORGE H. STOCKBRIDGE.

In December, 1885, Mr. Montgomery, then Commissioner of Patents, rendered a decision in which he held that a process and a product, or any two "kindred and auxiliary" inventions might be claimed in the same application. This decision was a reversal of his predecessor's judgment in *ex parte Blythe* (C. D. 1885, page 82). Whereas Mr. Butterworth had held that by employing the language, "art, machine, manufacture, or composition of matter," Congress had defined in the law itself certain distinct classes of invention. Mr. Montgomery denies this, in effect, and holds as follows: "Inventions may be distinct and not separate and independent; even if so distinct, if they depend upon each other and mutually contribute to produce a single result, if they are 'kindred and auxiliary,' if they are in their nature or operation connected together, if they are connected in their design and operation, they may be claimed in one patent."

The office practice under Butterworth had been to deny the right of inventors to claim a process and a product, or a machine and a product, or a machine and a process (for these groups have always stood on the same footing) in the same application. The *Blythe* decision did not go so far as to warrant this in direct language, but it was given that scope by the office.

Now, when the Montgomery decision in the case of *Young* was published, all this was changed. This decision also was interpreted somewhat differently from what its language would justify, but it led to the practice of combining in a single application duplicate sets of claims on the lines indicated. This practice continued nearly two years. During that time applicants and their attorneys filed, we will say, a thousand cases having claims based upon the *Young* decision. This was done with the clearest warrant, which was the office interpretation of *ex parte Young*.

On Oct. 19, 1887, Mr. Hall, the present Commissioner of Patents, took up the same subject and rendered a decision *ex parte Herr* (41 O. G., page 463), in which he says: "It must be regarded as settled by the very highest authority that an apparatus and a process are separate and distinct inventions. There is no requirement of law that they must or ought to be comprehended in a single patent, while there are many reasons why they ought not to be. A claim for a machine or apparatus and a claim for a process should be prosecuted in separate applications, and each, when allowed, should be comprehended in a single patent." There was no mistaking the meaning of this language. The result of it was that attorneys were notified, in the thousand cases I have mentioned, that the

1. Read before the American Institute of Electrical Engineers, May 16, 1888.

claims, or some of them, which they had filed in good faith and in accordance with the practice of the office, must be stricken out.

A secondary result was that inventors began to ask what their attorneys meant. "You told us," they said, "that we could cover both sets of claims by a single patent. What do you mean, now? Is this an attempt to squeeze us for another fee?" Well, of course, we had to explain. But the inventors then asked, "What does the *Office* mean? Is it possible that after fifty years no settled practice on this point has become established?" We had to answer, No. And in answering my own clients, I was led to consider just how safely such a statement might be made, and the result was the present paper.

Mr. Commissioner Hall expresses it in this way: "I approach the consideration of such a question with the greatest hesitation. It is one that has kept the attention of the office from its foundation up to the present day, and during the entire period there have been constant changes and variations of opinion on the part of commissioners, contrariety of decisions and diversified rules."

I have not seen fit to go back farther than eighteen years, during which time there have been eleven commissioners of patents, and four or five acting-commissioners during the interegna. In 1870 Mr. Commissioner Fisher made a decision in case of *William Lowe* (C. D. 1870, page 39). In this case the inventor, who had been allowed claims for an apparatus, sought to obtain a second patent upon the process which was conducted through his apparatus. In deciding the case on appeal, Mr. Commissioner Fisher said: "The first answer to this claim is, that it cannot form a subject of a separate patent. It is not a distinct and separate part of the thing patented in the original. The farthest to which the division of inventions has been pushed has been to grant one patent for the process and another for the product of that process. Such patents have, with some hesitation, been sustained (*Goodyear* vs. *Honsinger*, 3 Fisher, 150; *Goodyear* vs. *Wait*, 3 Fisher, 244; *Goodyear* vs. *Providence Rubber Company*, 2 Fisher, 510), but upon the express ground that this was a matter confided by law to the discretion of the commissioner. But I have never known one patent to issue for the machine and another for the law and principle by which it operates. The mechanism of application is of no possible value except to carry out this process. Aside from this it possesses no patentable utility. The process is of no avail unless carried on through the medium of instrumentality. (*Morton* vs. *New York Eye Infirmary*, 2 Fisher, 324.) It would be idle to sell the patent for mechanism and withhold that which covers its legitimate and only mode of operation. Separate patents for processes and products have been justified upon the ground that the product might be imported, and a patent for the process would give no protection; but the machine and its mode of operation cannot be separated."

Mr. Fisher was a man of very positive opinion, and he leaves no doubt regarding his views on the subject. But the views of his immediate successor, Mr. Leggett, are very different from his. (See *Murray* vs. *Wuterich*, C. D. 1873, page 96). He draws diametrically opposite conclusions from Judge Clifford's decision in *Goodyear* vs. *Providence Rubber Company*. Admitting that the office practice allowed a "machine and its product to be claimed in the same application and go out in the same patent," he sums up as follows: "Notwithstanding the precedents which exist, and admitting that such a practice as they indicate, if not strictly correct, is not fatal to the validity of patents, I think the time has come, when, leaving out of consideration the perspicuity of the patents themselves, and the revenue to be derived under the law for examinations, a proper classification in the office, so as to facilitate examinations and prevent mistakes in the issue of patents, requires that processes, machines and their products be presented for patent in separate applications."

Mr. Leggett resigned his office in October, 1874, and on the 23d of that month Acting-Commissioner Thatcher, in the case of Chamberlin (C. D. 1874, page 111), says: "All that can rightfully be claimed in this application is the machine and the link blank, which is the product of the machine." Here is plain evidence of difference of opinion. Mr. Thatcher evidently knows nothing about "a proper classification in the office, requiring that processes, machines and their products be presented for patent in separate applications."

I find no positive judgment of Thatcher on the subject, nor of the successor, Mr. Duell, although Duell deals with a case in which process and product claims are combined (Loeser, C. D., 1876, page 104) without adverse comment.

The next decision is that of Doolittle, Acting-Commissioner in 1877, in which he demands a division of the application of *Junker* and *Wolf*, on the ground that "the article is not necessarily the result or product of the action of the machine." This is in some sense a forerunner of Mr. Commissioner Spear's decision in 1878, which introduced a mode of treating such cases which prevailed for several years after him. His language is: "No rule of universal application can be given for this class of cases, more than for any other; but in each case, as it comes up for consideration, the inquiry must be made whether the process or machine and the products thereof are so separate and distinct that they must be called independent inventions."

This doctrine was affirmed by Mr. Paine in various decisions, notably in *Winterlich and others*, where he uses this language: "If the machine and the manufacture are so related that the former cannot operate without producing the latter and the latter can only be produced by the former, both may be united in one patent; but this is an exception to the general rule, which forbids the joinder of the machine and its product in one application.

Mr. Commissioner Marble, in *Bancroft* and *Thorn* (20, O. G., page 1,894), applauds the doctrine of his immediate predecessor and lets each case stand upon its own merits. Then came the Butterworth decision to which I have already alluded. He regards art, machine, manufacture and composition of matter as "statutory classes of invention." "Suppose," he adds, "there be invented something in an art, or, as it is ordinarily called, a process, also a machine for carrying out the process, and also the manufacture or article which is produced in the operation of the process by the machine. There can be no doubt but that the statute calls for three patents for these three things. It makes no difference if they are invented simultaneously or successively, by one man or by three. Their independence remains the same."

Now let us see what changes of practice have been introduced by the various decisions to which reference has been made.

Mr. Fisher's decision seems to have been a new departure and to have altered the previous practice of the office. At all events, it fixed the practice under his administration and made it a positive requirement to combine claims for a machine and its product in the same application.

Well, what happens next? Mr. Leggett demands that such claim shall be separated, to facilitate the work of examination. That is change No. 2.

Mr. Thatcher and Mr. Duell appear to have allowed the two sets of claims to be combined, though I find no decision of theirs directly on the point. If I judge rightly of their practice, it may be regarded as constituting change No. 3.

It is certain that Mr. Spear and his successors, Mr. Paine and Mr. Marble, followed the practice of settling each case according to its own circumstances. Call this change No. 4.

Mr. Butterworth returned, in effect, to the practice of Mr. Leggett (change No. 5); Mr. Montgomery, in effect, followed Fisher (change No. 6), and Mr. Hall has now brought back the Leggett decision, thus introducing again

a different practice from that of his predecessor in office (change No. 7).

I believe that if each commissioner had made himself the author of a new practice, there would have been three more changes than have actually taken place. However, I do not think more could have been expected; really, this is a very serious matter. The amount of annoyance and hardship imposed upon inventors in the way of unnecessary delay and expense is in the aggregate very great. I have no disposition to express an opinion as to which one, or whether any one, of the commissioners has been right in his judgment on the matter in question. I have no doubt that the decisions in every case have been drawn up with a conscientious regard to the responsibility of the office from which the decisions emanated. But I do think that inventors and all who are interested in inventions have a right to protest against the continuance of a system which admits of and invites such unjust and arduous practices. It would not matter so much what the practice was, provided it were uniform, although of course it ought to be right and fair to inventors. But without uniformity it is monstrously unjust.

Lest it be thought that I have selected a peculiar class of cases, I may hasten to deny it in advance and may add that the office practice has been frequently altered on many matters quite as important. Take, for example, the question whether more than a single claim may be made in an application for a patent on a composition of matter. At least two commissioners have answered, No, and at least two more have answered, Yes. And so with many other cases. The mere fact that appeals have been taken to successive commissioners on the same subject indicate the condition of affairs in the office.

What is the remedy for this evident evil? The best remedy yet proposed I conceive to be embodied in the bills recently laid before Congress by the Legal Committee of the National Electric Light Association. One of these bills provides that the salary of the Commissioner of Patents shall be $8,000 a year. I am not sure that the enactment of such a bill would not do away with two-thirds of the evils of the present state of affairs. It is probable at least that we should not have eleven Commissioners of Patents in eighteen years, if the salary were $8,000, and with less frequent changes in the head of the office there would be necessarily less frequent changes in the office practice.

But there is still greater promise in the other bill which provides for the establishment of a Court of Patent Appeals, which shall have appellate jurisdiction from the Commissioner of Patents "in all cases touching patentability of inventions, priority of invention among several claimants for patent on the same invention, and the *judicial practice of the Patent Office.*"

Such a court would be in the nature of the case a continuing body, and its decisions would be little liable to change. The enactment of the last clause quoted would give it authority and set up what has never been set up before in connection with the Patent Office—a controlling and continuing authority, governing the actions of the commissioner and, through him, of the primary examiners.

A SWINGING ARM GALVANOMETER.[1]

BY GEORGE S MOLER, A. B., B. M. E.

(Cornell University.)

The objects sought in the construction of this galvanometer were applicability to a great range of currents, accuracy of indication and portability. In passing from the measurement of large to that of small currents no change in the apparatus is necessary, and still throughout a wide range great sensitiveness is maintained.

These ends are attained by making use of the fact that the influence of a current on the magnetic needle varies with change of distance and with the angle which the plane of the coil makes with the horizon. The principles of the sliding coil galvanometer and of Obach's cosine galvanometer are thus combined. A movable arm is hinged to the base of the galvanometer, figure 1, and carries the coil, which is attached to its outer end. The length of the arm is such that in the vertical plane the needle will be in the axis of the coil. By means of screw clamps, the hinges are made to produce friction enough to hold the arm in any required position.

When the coil is brought up into the vertical plane it is very near the needle and a small current will produce a deflection. In this position, which is that of maximum sensitiveness (since the distance is a maximum and the angle which the coil makes with the horizontal plane is 90°), $\frac{1}{100}$th of an ampere produces a deflection of about 8 mm.

As the arm is carried down toward the horizontal position, greater and greater currents must be employed to produce the same effect. The position of the coil can be read upon a graduated quadrant which passes through it, there being a pointer attached to the coil and extending inward to the graduations.

The arm consists of two parallel bars of copper, terminating in the two hinges. These are insulated from each

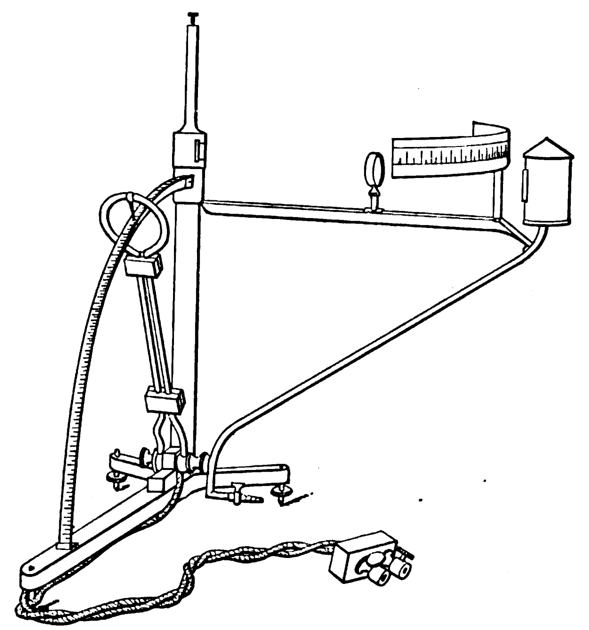

Fig. 1.

other, and from them two flexible conductors are carried to the extremity of the base; after that they are twisted together for a distance of about one meter and end in a block to which two large binding-posts are attached.

The coil is made of a copper rod 8.5 mm. thick, and its outside diameter is 76.5 mm. The radius of the graduated quadrant is 343 mm. and it is divided into twentieths of an inch. The radius of the lamp-scale is 381 mm. The scale forms the arc of a circle, having the galvanometer mirror for a centre. Its length is 500 mm., and it is composed of paper, rendered semi-transparent by being treated with castor oil.

The needle is shown in figure 2. It is a bell-shaped magnet carrying a mirror, which can be rotated slightly upon the suspension rod for the sake of adjustment.

The needle is suspended by means of a fine silk fibre, and is prevented from making a complete revolution by means of a stop. Its motions are dampened in the usual manner by the action of a surrounding cylinder of copper.

The rays of light from a small gas lamp, shown in figure 1, after passing through a lens, are reflected from the

1. Read before the American Institute of Electrical Engineers, by Professor E. G. Nichols.

mirror and then fall upon the scale. When the plane of the swinging coil is in the magnetic meridian and no current is flowing, the spot of light will fall at the centre of the scale. The lamp and scale are attached rigidly to the body of the instrument for the sake of rigidity and to avoid the necessity of repeated calibrations. In the lamp case is a small circular opening having a fine vertical cross-hair of platinum, and the lens is so placed that the image of the cross-hair is sharply defined upon the scale. All parts of the scale being equally distant from the mirror, as shown in figure 1, the definition of this image is equally good for all deflections.

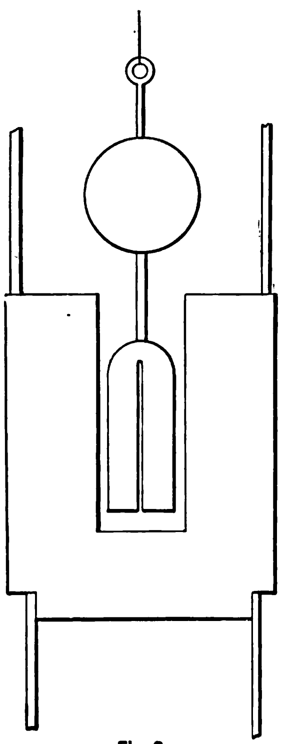

Fig. 2.

The swinging-arm galvanometer is especially designed to be used with the method of constant deflections. By carrying the coil up from the horizontal position, the spot of light will be deflected more and more, until the image of the cross-hair is made to coincide with the chosen mark upon the scale; the position of the coil is then to be read and the current found by reference to a calibration curve or chart. In the measurement of feeble currents, the chosen point on the lamp-scale may be near the position of no deflection, while for stronger currents it may be further away. Several deflection points may be thus chosen and a calibration by means of some standard instrument can be made for each; then, to insure greater accuracy in the determination of a current, several of these points may be used, and the mean of the currents indicated by them may be taken, giving to each its proper weight.

The instrument may also be used by taking different fixed positions for the coil and reading the deflections of the spot of light, calibrating for each of these positions as before. These two methods may also be combined by moving the coil until the spot of light is approximately in coincidence with a selected deflection point, observing its

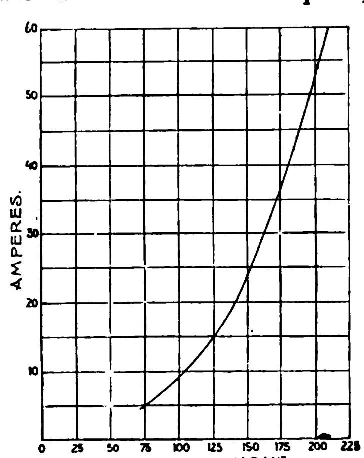

Fig. 3.

distance from the same and applying to the current value, by means of the previously determined figure of merit, the proper correction. In this way changes in a slightly fluctuating current can be followed and measured by moving the coil.

In order to indicate heavy currents to an audience in a lecture room it is only necessary to remove the lamp stand and scale and so make use of the stronger light of the magic lantern; the image of a slit in the field of the lantern, after reflection from the galvanometer mirror, being thrown upon a wall or screen. A position of the coil can then instantly be found which will produce suitable deflections for any given current, from a fraction of one ampere up to that which the coil and connections can be made to convey without destruction from heating.

In the curve, figure 3, and the accompanying table are given the results of a calibration of a galvanometer of the pattern just described, which has just been constructed in the department of physics in Cornell University.

The deflection selected was 10 cm., and the measurements, which extended from 3 amperes to 60 amperes, by no means covered the possible range of the instrument. The movement of the coil indeed covered only 200 of the 400 scale divisions into which the reading quadrant is divided.

The calibrations were made in the magnetic observatory of the university, in which locality the average value of the earth's horizontal intensity is .1713. The currents were measured upon the great tangent galvanometer.

Simultaneous readings were made upon that instrument and upon the swinging-arm galvanometer.

The readings of the great galvanometer, reduced to amperes, with the corresponding positions of the swinging coil for a deflection of 10 cm. are given in the following table:—

Calibration of the swinging-arm galvanometer between 5 amperes and 60 amperes constant deflection = 10 cm.

Current in amperes (large galvanometer).	Quadrant readings (swinging-arm galvanometer).	Current in amperes (large galvanometer).	Quadrant readings (swinging-arm galvanometer).
5.21	79.0	19.48	138.0
5.54	79.5	24.42	151.0
5.84	82.0	24.48	151.5
8.04	95.8	32.00	167.0
10.35	106.0	33.44	168.5
10.39	107.0	33.99	171.0
10.86	110.0	38.50	179.5
11.53	110.0	42 79	185.0
13.25	119.0	43.90	187.0
13.92	119.5	46.14	191.0
15.25	125.0	53.56	202.0
19 39	137.5	59.39	208 0

From these values, with the readings of the new galvanometer as abscissæ and currents in amperes as ordinates, the curve shown in figure 3 has been constructed.

From this curve the currents for intermediate positions of the coil may be determined and the degree of accuracy of which the instrument is capable may be estimated.

UNDERGROUND ELECTRICAL CONDUCTORS IN EUROPE AND AMERICA.[1]

BY PROFESSOR G. W. PLYMPTON.

The problems of construction of underground systems of electrical conduction will have been solved when the telephone and the arc light systems are both buried under our streets without impairing the efficiency or durability of either.

By this I mean that all the difficulties encountered in burying conductors are involved in converting telephone and arc light from *aerial* to *underground* systems. Telegraph lines and systems of incandescent lighting present fewer difficulties in the process of burying, and none of a kind not met with in dealing with the systems first mentioned.

The telephone problem is substantially solved. Some

1. Read before the American Institute of Electrical Engineers, May 16, 1888.

details only remain to be settled, among which may be mentioned the best size of conductor, the most serviceable insulation, and the maximum distance of effective service for either grounded or metallic circuits.

In Brooklyn the general plan adopted is that of a conduit divided into ducts through which cables containing from sixty to one hundred wires are drawn. The material of the conduit is for the most part creosoted wood. About ten miles of this is already in use in our city, and about four and a half miles of the Dorsett concrete conduit. For the extensions of the underground systems for the present year, only creosoted timber is to be used.

Among the lessons learned from our experience are: 1st—That in creosoted conduits the use of cables covered with kerite, or any similar rubber or gutta-percha compound, must be avoided. 2d—That in the so-called lead covered cables, the use of pure lead is also to be avoided, as it is slowly converted into a porous and friable lead carbonate. An alloy of lead with five or six per cent. of tin seems to resist the destructive action. 3d—That the conducting wire first used is too small for satisfactory telephone service. The difficulties of induction and retardation led to complaints as soon as 4,000 or 5,000 feet of underground wire was put in service. The cables that are now being put in are made up of wires whose cross-section is greater by one-third than that of the first wire, and they are protected by twice the thickness of insulation.

I mention the above conclusions as having been drawn from our own experience in Brooklyn.

In commencing our work we gathered such information as could be gleaned from localities where solutions of the problem had already been attempted. The impression so largely prevailed that in Europe all telephone and telegraph conductors were underground that our board decided that a personal inspection of European systems should be made by one of our number. The duty devolved upon me. The result of my inquiry has been published in the scientific papers.

I will briefly refer to a few of the incidents (Professor Plympton here gave an epitome of the third annual report of Brooklyn subway commission, which embodied his observations).

In regard to the burial of the arc light wires I can only say that no method yet tried seems certain of success. Most of them certainly insure the destruction of the underground conductors in from one to three years. But I have no doubt that a solution of the problem will soon be reached, although the system will be kept apart from the telephone and telegraph subway.

It does not seem likely that arc light conductors will be allowed in the same conduit with telephone wires, nor will they be distributed from the same man-holes.

In saying that, I believe that a solution of the problem will soon be found. I do not mean to assert that casualties like that recently recorded of a man in the Bowery, who lost his life by grasping the naked wire close to an arc lamp, can be prevented by any system of burying wires. To prevent such *accidents* (if that is the term to be used) the arc lights must be buried with the wires.

All past experience teaches us to proceed cautiously. Nothing can now permanently check the growth of the telephone, the telegraph or the electric light. They have become necessities of our civilization, and any hasty or ill-advised enforcement of the law to convert all aerial to underground systems which should result in serious injury to them, would prove the surest way to perpetuate the nuisances of overhead wires and poles in the streets.

.... THE strong points of the average executive committee of an electrical corporation are, an innocence of electrical knowledge; an inability to distinguish between the two words "economy" and "parsimony," and an indisposition to see that a dollar properly expended to-day means a good many saved throughout the year.—*Thomas D. Lockwood.*

ABSTRACTS AND EXTRACTS.

ELECTROLYSIS OF IRON SALTS.

BY ALEXANDER WATT.

(Continued from page 176.)

Double Carbonate of Sesquioxide of Iron and Soda.—In this experiment it was desired to ascertain what kind of a deposit would be obtained from an alkaline solution. To form the electrolyte, a strong solution of bicarbonate of soda was first prepared, into which freshly precipitated carbonate of iron was gradually introduced, and the mixture well stirred. When it was found that the soda solution had taken up as much of the iron salt as it was capable of doing, the vessel was set aside for an hour or so, and the clear liquor then decanted off for use. The current from five Daniells was employed, and a copper cathode as before. In a few moments after immersion the copper plate became coated with a fine white deposit of iron. There was a brisk evolution of gas at both electrodes, and after a short time the solution acquired a brownish tint; the bath, however, continued to yield good deposits of iron for a considerable time, and the anode kept remarkably clean.

Sodio-Citrate of Iron.—A solution of this salt was prepared by dissolving recently precipitated carbonate of iron in a hot and strong solution of citric acid, and then adding carbonate of soda. The solution was next diluted with about two parts of water. With a current from five cells a metallic deposit was obtained at once upon a strip of copper, but this quickly assumed the color of "blued" steel, for an instant only, however, when it again acquired the characteristic color of metallic iron; the deposit, which chiefly occupied the lower surface of the plate, refused to cover the surface nearest the top of the fluid.

Acetates of Iron and Soda.—The electrolyte was formed by dissolving recently precipitated and moist carbonate of iron in acetic acid to saturation; the solution was then diluted with twice its bulk of water; acetate of soda was then dissolved in the liquid, and the solution was ready for use. The current from five small Daniells, in series, was employed, and a copper plate used as the cathode. Immediately after immersing the receiving plate it became coated with a bright and silvery white film of iron, the deposition taking place very uniformly, and the coating well retaining its character. There was a moderate evolution of gas, and the anode remained clean and bright.

Potassio-Citrate of Iron.—A solution of this salt was made by dissolving recently precipitated and moist carbonate of iron, prepared with carbonate of potash, in a strong and hot solution of citric acid. The citrate solution thus obtained was then neutralized with carbonate of potash, and was then tried in its concentrated form, when the receiving plate (a strip of sheet copper) soon became coated with a metallic film of a dark green color. The liquid was next diluted, and a fresh plate immersed, which at once received a coating of bright metal, but not of so good a color as that obtained from the simple citrate of iron. The plate was allowed to remain stationary for a minute or two, when the dark green film again appeared upon its surface. A freshly-prepared plate was now substituted, and this was kept in brisk motion while in the bath, when a silvery white film was obtained which strongly adhered to the plate. The solution was now further diluted to see if a bright reguline deposit could be obtained upon a stationary plate. Such was not the case however, for shortly after a layer of white metal had been deposited, the coating again became covered with a dark green film. When a newly-prepared plate was immersed, and kept in rapid motion, the deposit was of a good reguline character, very white, and, as before, very strongly adherent. In working this solution it was noticed that the metallic deposit, as in some other cases, commenced at the upper portion of the cathode, gradually proceeding downwards.

Chlorides of Iron and Potassium.—Solutions of the respective salts were mixed, and electrolyzed with a current from two small Daniells. Only a slight trace of metal appeared upon the upper part of the cathode, while a copious dark green salt was formed, which in a few minutes floated on the surface of the liquid to the depth of about half an inch.

Perchloride of Iron and Chloride of Potassium.—A solution of chloride of potash was added to one of perchloride of iron, and a current from two Daniells employed. A copper plate promptly became coated with a bright film of iron of good color in this solution, the anode surface being about one-half that of the cathode. There was a brisk evolution of gas, with which the solution soon became impregnated throughout. After a short immersion the plate became spotted in parts with minute dark specks, which were easily removed by scouring with silver sand. The plate being again returned to the bath received a further coating of white metal, which appeared to be exceedingly tough for electrolytic iron, for when a corner of the coated plate was turned down, forming a sharp bend, there was no evidence of the deposited metal having separated from the underlying surface of copper. It was noticed that the anode kept perfectly clean during the electrolysis. This result from a persalt of iron was highly satisfactory.

(*To be continued.*)

THE FRANKFURT-OFFENBACH ELECTRIC TRAMWAY.[1]

BY E. KRAUSE.

THIS tramway was constructed on the main road between Frankfurt and Offenbach on the Main, and has been in continuous operation during the last four years. Tram rails of the usual street railway pattern used, level with the road pavement.

The whole length of the line is 4.14 miles. It is a single track line, but there are short side tracks at the termini for shunting the carriages, and at three passing places, distributed at nearly equal distances over the whole length, dividing the line into four sections. This makes it possible to increase the working capacity of the line and to have two trains going up and two trains going down at the same time. There are at present nineteen stations. Many curves and gradients make the working of this line difficult; the stiffest incline is 1 to 32 for almost 100 yards distance, another 1 to 45 for 150 yards, with a curve of 110-feet radius. The gauge of the track is one meter.

The conductors are overhead. Slotted wrought iron tubes are used for conveying the electric current along the line. The tubes are of 1 in. internal diameter and $1\frac{5}{8}$ in. external diameter, and are slotted on the under side as shown, full size, in figure 1.

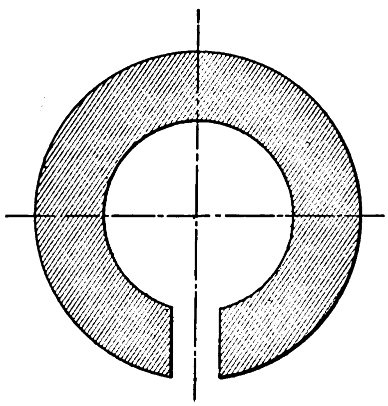

Fig. 1.

The length of the tubes is 15 feet; they are well bored out, and are perfectly smooth and clean, so that the internal surface offers as little mechanical or electrical resistance as possible to the contact carriage sliding within. The tubes are screwed together by means of sockets in the usual way and then soldered. About 90 feet apart, but much closer in curves, wooden poles are erected on one side of the road, on which cast-iron brackets, as shown in figure 2, are fastened. The brackets carry two iron-hooded insulators, on which the tubes are suspended by means of iron hooks. The poles are 18 feet high, and the tubes are placed about 15 feet from the ground. To prevent the suspended tubes from sagging two stout iron-wire ropes are stretched over insulators fastened on cast-iron brackets on the top of the poles all along the line, and the tube conductors have generally two supports between two poles, being attached by clamps, to the ropes as shown in figure 3. The expansion of the conductors during hot wêather causes more sagging than in cold weather, when the conductors are almost straight; this, however, does not appear to impede the moving contact carriage. The resistance of the whole line of tube conductors is only 1.6 ohm.

The three turn-out tracks necessitated the arranging of three passing places in the overhead conductors for the contact carriages of the two passing tramcars. This has been done in an ingenious manner, as shown in figure 4. The two parallel slotted tubes R and S are gradually bent, and where they would meet a part has been cut out and replaced by a well-seasoned piece of hard wood. The two tubes are partly let into it, and the bores and slots are cut through the wood. On the other end of the wooden piece H the tubes G and I, continue the conductors. Thus the four tubes are insulated one from the other, and the contact carriage can slide from tube R to I, or from G to S—in other words, can go up or down the line. To connect the positive leads S and G, and the negative conductors R and I, two metal pieces *m* and *n* are arranged above the wooden block H insulated from each other (*see* figure 5 in section), and screwed to the corresponding tubes. To complete the passing place for the conductors the tubes L and K are joined to the tubes S and R, as shown in figure 4. When the contact carriage goes up or down the line it is necessary to direct it into the right tubes, which is effected by two movable tongues, *t* and *z*, pivoted at *p*, and shown in figure 6 in section. These tongues are always kept in the position shown in figure 4 by means of springs (*see* figure 9), acting on the turned end of the tongue. If a contact piece slides in R to the left, it will easily go into tube I—the tongue closes the way into K—and if a contact piece in G moves to the right, it will slide into tube S, pressing the tongue *t* aside.

This arrangement requires the contact carriage to be constructed in such a way that while passing through the wood block

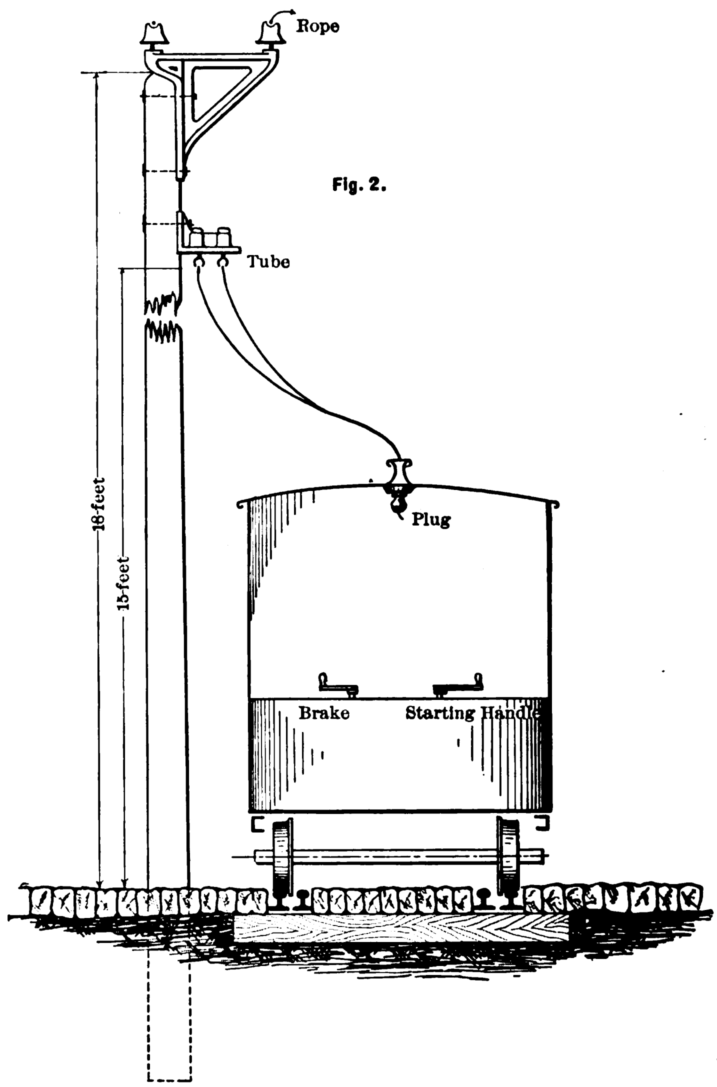

Fig. 2.

H the flow of current to the tramcar be not interrupted, and also that it follow with perfect ease the curves of the conductors. Figure 8 shows the tube conductor in longitudinal section and the contact carriage in elevation. Figure 9 is a side elevation. Within the tube slide two cast-iron pistons, C C, with pointed ends and flat projections below, B, fitting into the slots of the tubes. These projections are riveted to a steel band, A, of $\frac{3}{4}$ in. width and $\frac{1}{16}$ in. thickness, which carries in the middle a bent brass piece, D, screwed to it. Besides the steel band connection two

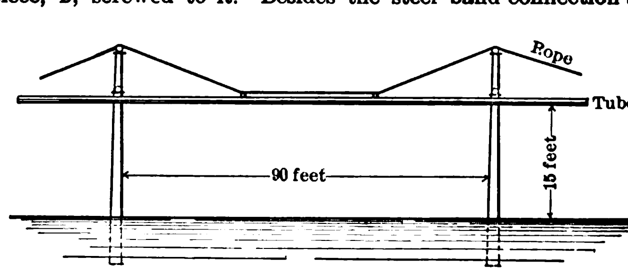

Fig. 3.

small copper wire ropes (not shown in figure 8) connect D to the right and left with the projections B, and securing a safe passage for the current. The brass piece D contains also the insulated copper wire conductor E, which is fastened to a rope, F, leading with the conductor E into the tramcar. On both ends of the steel band A are fastened two brass pieces carrying a steel rod, *d*, parallel to the tube conductor. Two metal pieces, *f*, screwed together

1. From *The Electrician*, London. Abridged.

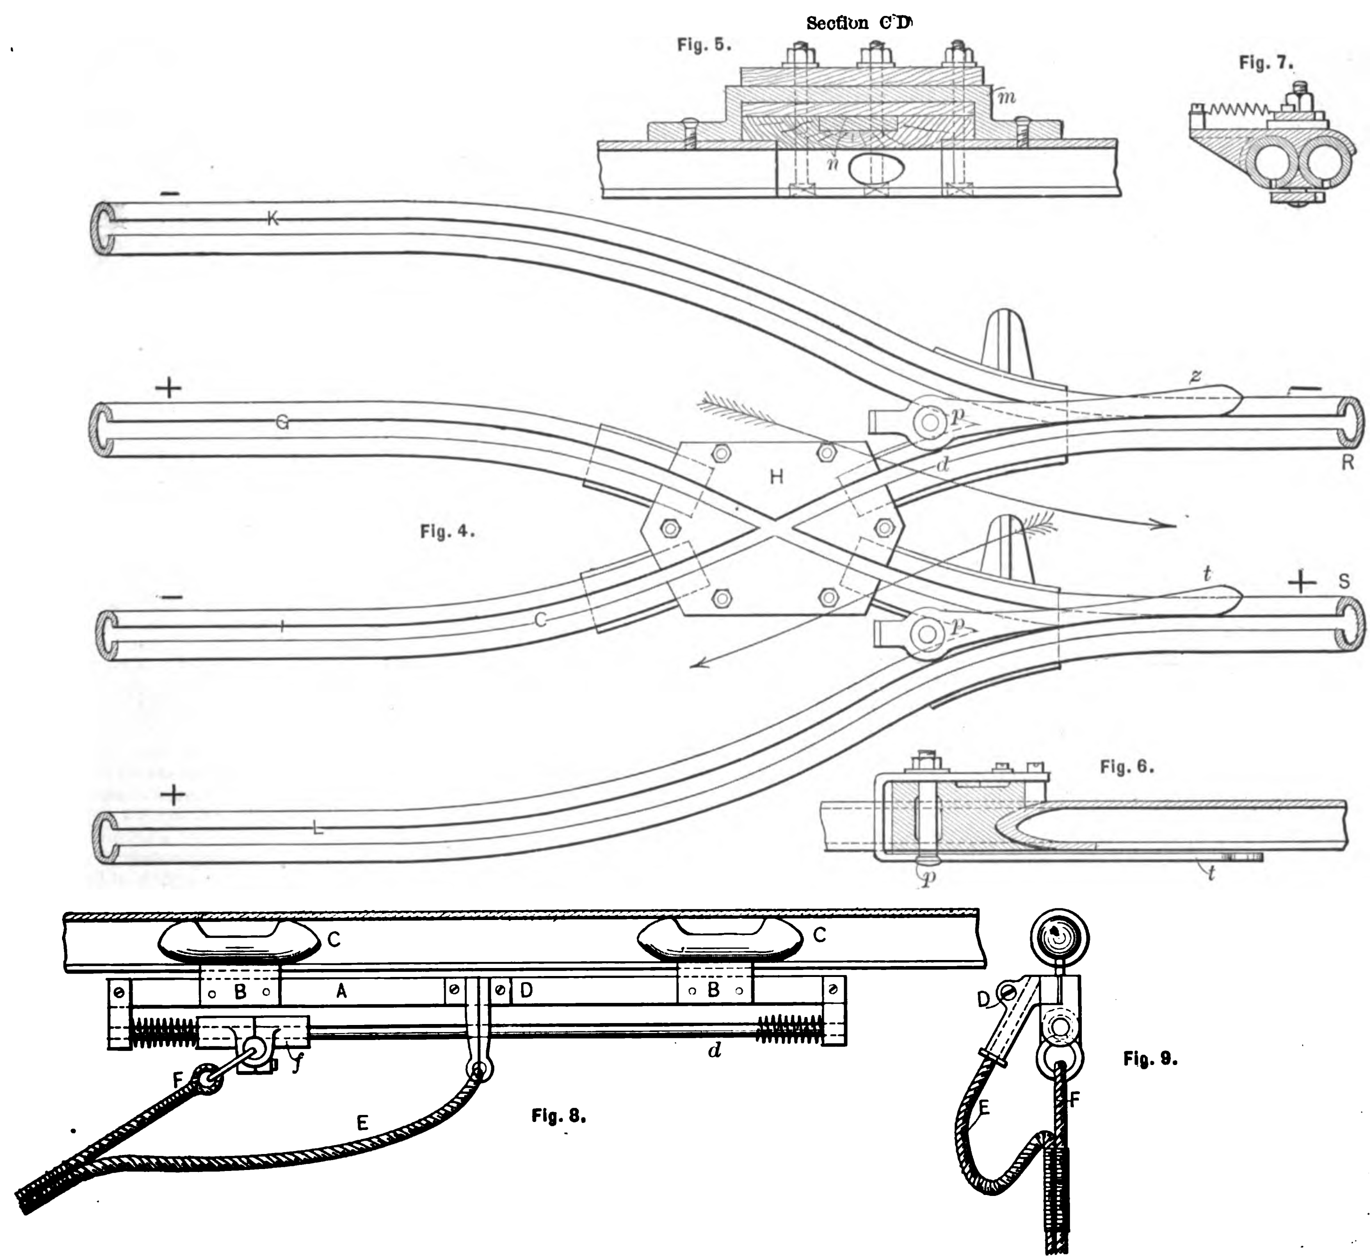
slide on this rod, and carry between them a ring, to which the rope F is fastened. Rope F takes off the conducting wire rope E the strain caused by the moving of the tramcar. The two spiral springs on the rod *d* act as buffers when the pull is in one or the other direction. This arrangement has given great satisfaction during the four years' working of the line, and fractures of the rope F and copper wire E, which during the first few months' working frequently occurred, happen now very seldom.

The central station for generating the electric current has been erected about the middle of the line in Oberrad. In the boiler-house three large cylindrical boilers are provided with inclined fire bars. The working steam pressure is 88 lbs. Under ordinary circumstances one boiler is sufficient to generate the necessary steam, but at times, when much traffic takes place, two boilers are in use; the third is a spare one. In the passage leading to the engine house two double-acting feeding pumps are put up, and close by is a deep water well.

The engine house contains two separate large horizontal engines, both fitted with automatic expansion gear. The larger is a twin engine, with modified Sulzer valve gear of 240 h. p., but only one cylinder is at present used. This engine was built by Mr. R. Küchen, in Bielefeld, and cost £1,400. The other engine, which has lately been erected, is a single cylinder one of 120 h. p., fitted with the Collinann automatic valve gear, the cut-off being capable of variation by the governor from *nil* to three-fourths of the stroke. Both engines are well suited for the heavy work, which consists of nearly eighteen hours' daily run, with only twenty minutes' stoppage during dinner time for lubricating purposes.

The countershaft is provided with couplings, and can be driven by either engine independently of each other; it has been arranged 20 inches above the floor, and makes about 300 revolutions.

There have been erected four vertical compound-wound Siemens dynamos, mounted on bed-plates with belt tightening gear, each capable of generating a current of seventy amperes and 300 volts — 21,000 watts, and absorbing about 40 indicated horse-power each. There is room for four more dynamos. On week days, under ordinary circumstances, when only four tramcars are running, two dynamos will suffice to do the work, one engine working with one-half power; but with eight electric trains on



Figs. 4, 5, 6, 7, 8, 9.—Details of Overhead Conductors at Crossing Points.

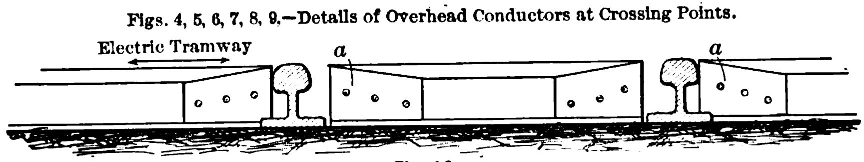


Fig. 10.

the road the engines indicated 164 h. p. There is also provided a repairing shop, with a track of rails leading into it for repairing the electric cars.

The rolling stock of this electric railway consists of 10 electric cars and four ordinary tramcars; the former weigh about four tons, carry 36 passengers, and cost £500 each; the latter weigh about two tons, and carry 24 passengers. The electric car is much stronger in its frame, which consists of channel iron, and carries under the floor the electric motor. The armature makes about 500 revolutions per minute, and has a diameter of 15 inches, and is about 19 inches long.

The method of gearing in this case consists of two pairs of spur wheels. The pinion on the motor shaft is of gun-metal, and has a diameter of six inches, 15 teeth and a width of two-and-a half inches. In this gears a steel wheel of 22 inch diameter with 55 teeth, mounted on a countershaft, which also carries a pinion of 12 inches diameter and 26 teeth. This drives a wheel of 24 inches diameter and 52 teeth, keyed on to the tramcar axle. The tramcar wheels are of 30 inches diameter. The total ratio of speed is, therefore, $\frac{55}{15} \times \frac{52}{26} = 7.3$, and with 500 revolutions of the motor the speed of the electric car will be $\frac{500}{7.3}$ $7.85 \times = 537$ feet per minute, or 6.1 mile per hour.

The traction force on tramways amounts, according to Mr. Reckenzaun's tests, to 25 pounds per ton rolling load on a level line, and the horse-power necessary to propel a train consisting of

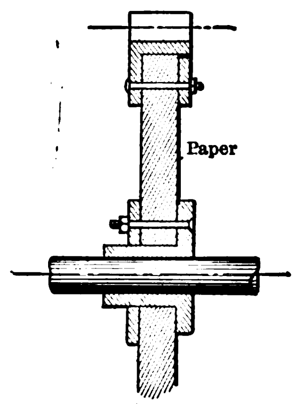

Fig. 11.

an electric car and an ordinary car, both with full load, with a speed of six miles an hour on a gradient of 1 to 32, will be found as follows :—

1 electric car, dead weight................	4	tons
1 ordinary car, dead weight...............	2	"
Passengers..................................	4.5	"
Total..................................	10.5	tons

$$\text{H.-P.} = \frac{W.\ K.\ S}{33000} + \frac{W.\ .2240\ S}{33000} \sin.\ \theta^*$$

$$\text{H.-P.} \quad \frac{10.6 \times 25 \times 537}{33000} + \frac{10.5 \times 2240 \times 537}{33000} \times \frac{1}{32}$$

$$\text{H.-P.} = 4.2 + 11.9 = 16.1.$$

If there are four such trains on the line, and the total efficiency taken to 40 per cent., the horse-power required to work the line would be $(16.1 \times 4)\ 1.6 = 103$ h. p.

There were several difficulties to overcome besides following the road in all its curves and gradients. For the electric tramway crosses once an ordinary horse tramway and several times the state railways, which are built on the same level. The rails of the former were cut and provided with chilled iron crossings as usual, but the latter were not allowed by the state railway authorities to be channelled for the passage of the wheels of the electric tramcars. It was therefore necessary to arrange on these rails wedge-shaped steel pieces, *a* (*see* figure 10), allowing the flange of the car-wheel to climb over the state rails as smoothly as possible. This, besides a tendency to derailment, had the great drawback that the steel tires of the wheels were worn in comparatively short time, and it was always necessary to drive very slowly over these railway tracks, or the inmates of the cars were subjected to very unpleasant joltings, as visitors will remember.

The gear-wheels at first used were of a somewhat elastic construction, consisting of a spider keyed to the shaft, having a toothed rim round it; the four projections of the spider pressed against india-rubber buffers inside the rim, and thus gave a certain amount of elasticity to the gear, with the intent to ease the starting. But now the cast steel rim of the wheel and the nave are connected by a disc of compressed paper (*see* figure 11), which construction has given good results. On each end of the tramcar are provided two levers, one for the brake, which is arranged as on ordinary tramcars, and one for starting the motor and regulating its speed. If two electric cars are coupled together, forming one train, the starting gears on both are mechanically connected, and the driver in the first car has perfect control over both motors. The brakes on both cars are now also mechanically connected. The cables for conveying the current enter the car through two tubes fastened on the roof of the car, and are brought under the floor to the brushes of the motor. Plugs are arranged in the roof above the driver's head, the drawing of which, in cases of emergency, interrupts the circuit, and consequently stops the motors.

The overhead conductors show scarcely any sign of wear, which may be due in part to the frequent cleaning and greasing of the tubes; the cast-iron pistons sliding in them last from five to six weeks, when they have to be renewed, the cost of which is very small. The greatest wear and tear are found in the gear-wheels. The metal pinion wears out in about six weeks; helical teeth have given better results. Heavy snow has given much trouble in the winter to this exposed line, and occasionally interrupted the traffic for a few hours. The trains run every twenty minutes from 6 A. M. till 11 P. M., and over one million passengers were conveyed during last year. On the whole the working of this line has been very satisfactory, and is greatly to the credit of Messrs. Siemens and Halske, who supplied the electrical plant.

ELECTRICAL STRESS IN DIELECTRICS.

At the meeting of the Society of Telegraph Engineers, London, held on the 22d inst., a paper on the above subject was read by Professor A. W. Rücker and Mr. C. V. Boys.

Professor Rücker, in introducing the subject, referred to the researches of Ker, Gordon, Quincke, and Röntgen on the stress in dielectrics placed between conductors at different potentials, and mentioned that Professor S P. Thompson had exhibited a lecture experiment to his classes, illustrating the stress in bisulphide of carbon. The authors did not profess to give any new results, but in view of the importance of a general recognition of the fact that electrical action takes place in the dielectric separating conductors they had devised some experiments which would exhibit these actions to an audience.

The first experiment shown was the introduction of a slab of paraffine between the plates of a charged condenser in connection with the two pairs of quadrants of an electrometer, showing the increased induction owing to the specific inductive capacity of paraffine being greater than air. That the effect was not due to a film of moisture on the surface of the paraffine acting as a conductor was shown by touching the paraffine, which did not alter the deflections of the electrometer; but when the paraffine was coated by tin plates, though the same deflection was produced in the first place, the needle flew back when this metallic casing was touched. Maxwell arrived at the conclusion that the stress in the medium was of the nature of a hydrostatic pressure perpendicular to the lines of force, combined with a longitudinal tension along the lines of force. A kind of crystalline structure should therefore be produced in the medium, so that we should expect its action on light to be similar to that of a crystal with its axis parallel to the lines of force. It was shown that when plane polarized light passing through a glass plate placed between two Nicol's prisms is extinguished by turning the second Nicol, the light is partially restored when the glass is subjected to stress. Some experiments due to Ker on electrical stress in bisulphide of carbon were then shown, with the modification of using long cylinders as conductors in the place of spheres, in order to increase the thickness of the medium, and magnify the effect sufficiently to render it visible when projected on a screen. A glass and wood cell, cemented with shellac, and containing two parallel cylinders immersed in bisulphide of carbon, was placed between two Nicols and traversed by a beam of light parallel to the axis of the cylinders. It was then shown that after extinction had been produced, the light passing through the annular space between the cylinders again became visible, when they were oppositely charged, by means of a Wimshurst machine, showing that the attraction was accompanied by stress in the intervening medium. Two cylinders, connected together, and placed between a pair of metallic plates, also in connection, were then charged, the pair of plates and the pair of cylinders forming the electrodes, and it was shown, as before, that the repulsion between the similarly charged cylinders was accompanied by a state of stress in the medium between them. The existence of stress was then shown in the case of a Franklin's pane, with bisulphide of carbon as the dielectric instead of glass. In a similar Franklin's pane, but containing windows in its lower half, the restoration of light was greater in the upper half, which would be expected on Maxwell's theory; while, if the effect was due to irregularities of action at the edges, there ought to be a greater restoration of the light

* Vide *The Electrician*, January 6th, 1888, page 209.

passing through the lower half. The phenomenon of Newton's rings was reproduced by means of a pair of plates, one of which was plane, while the opposed face of the other was a portion of a convex cylindrical surface, the colors being due to the varying stress in the bisulphide of carbon separating them, the stress, of course, being greatest where the distance separating the conductors was least. Some beautiful chromatic effects were also shown by means of Franklin's panes, with the aid of quartz and selenite plates.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The City Press Castigates the Arc Lighting Companies.—Coroner's Inquest on the Death of Thomas Murray.—Mayor Hewitt as a Cantankerous Witness.—His Honor Withdraws from the Board of Electrical Control.—Screening the East River Bridge Lights.—Electrical Science in the Board of Aldermen; the Love of Boodle Still Prevalent.—Fire at the Edison Station on Liberty street and the 39th street Telephone Exchange.—Meeting of Subway Workmen.

THE daily press has devoted much space during the past month to an arraignment of the arc lighting companies for the dangerous condition of their wires throughout the city. It is worthy of note, however, as pointed out by Mr. Powers, of Troy, at the recent meeting of the American Institute of Electrical Engineers, that the practice of abandoning telegraph and telephone wires is really the most objectionable feature of the existing overhead systems. There is a vast number of private lines in the city, the owners of which as has been said of the patent office are "responsible for nothing, and responsible to nobody." If the use of copper line wire was compulsory this evil would be remedied at once, as the pirates of the housetops would see ample financial inducements for removing "dead" wires to the nearest junk shop. The death of Thomas Murray, the Brush company's lineman, was a case in which carelessness of the victim was combined with neglect of the corporation. It is not good practice to leave a "dead" loop in circuit, when a subscriber has been discontinued, as every surplus foot of wire, adds to the possibility of trouble, and even if permitted to remain it should be cut entirely clear of the main line. The inquest upon the body of Murray, conducted by Coroner Levy, has been of unusual interest by reason of the peculiar character of the testimony elicited. Foreman Siers, of the Brush company, posing as a lineman of great experience, considers the lines of that company as being in first-class condition. Mayor Hewitt, when called upon, said flatly that he knew nothing about the case. The jurors did not take kindly to his honor's manner of testifying or rather refusing to testify, and he is to be called before that body once more, when it is intimated he will be compelled to give satisfactory replies to the questions of the coroner, or possibly held for contempt like the ordinary citizen. It would have been an unique spectacle had his honor been placed in charge of Fatty Walsh, until he promised to be a good boy. The mayor's dramatic withdrawal from the Board of Electrical Control on May 10th under a display of oratorical fireworks by Commissioner Gibbens, was a choice morsel for the reporters. He was really harmless, but his sarcastic criticisms of his colleagues were decidedly unpleasant to gentlemen of such dignity as Commissioners Hess and Moss.

At the request of the lighthouse board, reports have been made by Major Heap and Lieutenant Millis as to the best remedy for alleviating the annoyance to pilots arising from the dazzling glare of the arc lamps on the East River bridge. Major Heap suggests the use of ground or colored glass globes as an experiment, and if these are not successful that screens should be used. Superintendent Martin, of the bridge, says it is proposed to apply reflectors to the lamps which will not only screen them but confine the light to the bridge, where it will be beneficial to the public.

The board of aldermen refused to concur in the report of its committee in favor of permitting the use of electric cars on the Fourth avenue line. The discussion in the board was a model of scientific misinformation. Alderman Dowling, confounding the harmless methods of a storage battery motor, with the "deadly wires" of the press, drew a heartrending picture of the dangers to which the innocent passengers would be subjected. "Suppose" said he "that the insulation was broken, or a wire and a nail, a piece of iron or a screw came in contact with it, and suppose a passenger with a steel nail in his boot heel should step on this. He would be killed!" The popular supposition appears to be that the allurements of boodle have not been altogether neutralized by the ventilation of aldermanic methods in the Sharp trial.

The branch station of the Edison company at 62 Liberty street was seriously damaged by fire on the morning of May 23d. This is a small auxiliary plant, used in connection with the Pearl street central station during the winter season, when the latter is sometimes overtaxed on dark days. It had been shut down for a week, and the fire is supposed to have originated from spontaneous combustion in a pile of greasy waste. The machinery was seriously damaged by both fire and water. The property was fully insured.

The night of the 23d, the 39th street exchange of the Metropolitan Telephone and Telegraph Co. was badly damaged by a fire which is thought to have originated from the current entering the switch-board from an arc lighting wire. The location of the supposed cross has not been determined. The prompt arrival of the insurance patrol and their effective protection of the switch-boards and other machinery with tarpaulins made the loss much less serious than was at first supposed. Telephonic communication was, of course, generally interrupted through the exchange, but a large force of men is actively engaged in repairs, and it is believed that within a week the service will be practically restored.

A meeting of the subway workmen has been held, at which some indignation was expressed because the work is not given out in larger portions. They are of the opinion that 2,000 instead of 800 men should be employed, and would be if permission was given to open the streets.

NEW YORK, May 30th, 1888.

PHILADELPHIA.

A Suggestive Address on Wasteful Engineering.—The Rapid Transit Electric Railroad Company to Test their Motors in Philadelphia Streets.—The Legality of the Penn Electric Light Company's Underground Franchise Questioned.—The Philadelphia Electrical Society; Its' Investigation of Protectors against Heavy Currents.

BEFORE the Franklin Institute recently, William Barnet Le Van read an interesting paper on the decline of engineering, illustrated by examples taken from local practice.

He said no profession is so little understood by the general public as engineering. A work requiring the expenditure of a large sum of money might be made one per cent. more profitable by the best than by the second best engineer. The gentleman went on to say that it is apparent that the first object in most engineering works is, that they be made to pay those who obtain the charters without any regard for the shareholders or the benefit to the public. Great works are extravagantly arranged, located, and operated. Economical power is wanted, and the secret of economy lies in adapting the highest practicable pressure of steam, thorough jacketing, the earliest cut-off at which the engine will run, and as perfect condensation of steam as possible after the steam has done its work.

The best engines are easily worth their cost. Mr. Le Van then devoted some time in referring to various enterprises recently established, among which were the Brush electric light plant and that of the Edison Lighting Co. He said the former might have been more cheaply located on the river. After making some interesting calculations as to the expense in such case, the gentleman made reference to the waste of steam in the city of Philadelphia, which he characterized as inconceivable. The earning power in dollars and cents of the waste steam power would feed and clothe all the poor in the city. Mr. Le Van closed with a glance at civil engineering, observing that, for the sake of economy, a road must be ran as straight as possible, as subsequent straightening and improvements would cost double.

Council's electrical committee, a few days ago took up an ordinance providing for a practical test of the Rapid Transit Electric Railroad Co.'s motor.

The bill provided that the consent of council shall be given to the use of Twenty-ninth street so far north of Norris street as it may be opened, for the purpose of demonstrating to councils the practicability of the operations of the electrical cars.

Mr. Crawford Spear, on behalf of the company, made a brief statement of its intentions, and claimed that this electrical system would largely do away with the demand for elevated railroads.

On Mr. Freeman's motion, the bill was amended so that the tracks shall be laid north of Diamond street in order to avoid the necessity of tearing up Twenty-ninth street, between Norris and Diamond.

A clause was added requiring that security in the sum of $10,000 shall be given in order to bind the company to restore the street to its original condition should the road be abandoned.

With these amendments it was agreed to report the bill favorably.

At a meeting of councils law committee the matter of the legality of the ordinance by which the Penn Electric Light Co., of New Jersey, was allowed to lay conduits in the streets all over the city, was brought up.

After a speech by Mr. Scott, in which he contended that the ordinance was unlawful, and that the laying of the conduits in the form of cheap board boxes was merely a cloak by which the streets were to be held in possession by the company, the whole subject was referred to a sub-committee, which was instructed to obtain an opinion from the city solicitor on the subject.

The rooms of the Philadelphia Electrical Society, at 1714 Chestnut, have been made very attractive for the electrical student. All sorts of apparatus and devices in the electrical line are always to be found there for testing and experimenting purposes. The society hold weekly meetings, and seem to be in a prosperous condition.

The frequent accidental crossing of the electric light with the telephone and other conductors, thereby causing dangerous fires in this city, has directed attention to the necessity of some device to protect the telephone and telegraph instruments, and the electrical society has been making tests to determine the very lowest possible dangerous current.

A few evenings since a trial test of protectors was made at the society rooms at which several automatic protectors were tried, but the current although dangerous, was too feeble to work them. Then came several which opened or broke the circuit. The result of the experiment showed particularly fine work on the part of the protector known as the "Plush," which is in general use by the Western Union company and at a number of the Bell telephone exchanges. It was demonstrated that any current which will do damage will cause the lever of the "Plush" protector to fall. The advantage of this instrument was shown by the fact that when an abnormal current caused the lever to fall, it was restored to its place by the hand. No stringing of any fine wire is necessary.

PHILADELPHIA, May 16, 1888.

BOSTON.

The Refusal of the Supreme Court to Rehear the Telephone Cases.—Mr. Thomas A. Watson's Prediction of the Influence of the Telephone in Politics.—A Bond Issued by the American Bell Telephone Co.—Statement of the New England Telephone Co.—The Illegal Conduit Order Passed over the Mayor's Veto.—The Conduit Question in the Legislature.—The Telephone Companies Continuing to Lay Wires Underground.—Competition of Police Signal Systems.—Electric Light Casualties.—An Edison Electric Light Plant for Charlestown.

BY the decision of the Supreme Court rendered on the 14th inst., refusing to reopen the telephone cases, the great controversies relating thereto would seem to be at an end. It has been a persistent and hard fight on the part of each contestant, and of the defenders of the Bell patents. In the year 1880, in conversation with the writer, Mr. Thos. A. Watson, who has been called the "assistant of Mr. Bell" in the development of the invention, remarked, in his enthusiasm regarding the future of the telephone, "that it was destined to create great commotions in the industrial and even in the political interests of this country." His idea being that the telephone interest would be so great, as to enter the domains of politics in the questions that would arise concerning its use and extension. Mr. Watson's remark has often been recalled since the *furor* created by the Pan electric cases. The part of the National Administration in those cases may become more and more a factor in the presidential campaign now upon us.

The American Bell Telephone Co. are to issue $2,000,000 seven per cent. bonds, each stockholder owning 50 shares to have the right to subscribe for a $1,000 bond; the bonds are to be redeemed in 10 years, and the company to have the right to call them in after two years from date of issue at $110 and accrued interest. The money obtained in this way is to be used in construction of ong-distance telephone lines.

The comparative earnings of the New England Telephone and Telegraph Co., from their report for 1887, are given thus:

	1887.	1886.	Increase.
Gross	$1,011,836.53	$919,109.64	$92,726.89
Expenses	727,184.92	659,695.89	67,489.03
Net	$284,651.61	$259,413.75	$25,237.86
Dividends	259,413.75	210,000.00	49,413.75
Balance	$25,237.86	$49,413.75	*$24,175.89
Total surplus Dec. 31.	$127,151.61	$101,913.75	$25,237.86

*Decrease.

The mayor's message, returning without his approval the order granting to Henry E. Cobb and others the exclusive right for 20 years to build conduits in certain streets, was taken up on motion of alderman Gove, at the meeting of the board of aldermen on the 7th inst., and without debate the board, by a vote of eight to four, passed the order, the objections of the mayor to the contrary notwithstanding. The vote was as follows:

Yeas—Aldermen Eddy, Gove, Kelley, McLaughlin, Murphy, Rogers, Short and N. G. Smith.

Nays—Aldermen Allen, Doherty, C. W. Smith and Wilson.

Mayor O'Brien instructed the superintendent of streets on the 8th inst., to issue no permits to Henry E. Cobb and others to dig up the streets for the purpose of building conduits. His honor says:

"In the first place, the company has got to file a bond that is satisfactory. If they begin to dig up the streets without a permit the police will arrest them, and that will get the matter before the courts. The police have standing orders to arrest anyone who digs up the streets without a permit. My instructions to the superintendent of streets are final; he has no option in the matter."

The common council are not in accord with the other branch of the city government, concerning their action in the conduit matter, and can only "resolve," as they did on the evening of the 19th ult., as follows:

Resolved, That the board of aldermen as surveyors of highways possess a dangerous power, which should be curtailed or limited by legislation.

Resolved, That their recent action on the conduit orders, in granting extraordinary privileges to a private corporation for 20 years, in secret session, was the most outrageous legislation ever passed by the board, and calls for an immediate and decided change in the laws to protect our citizens and taxpayers; it is therefore

Resolved, That in the opinion of the common council, the board of aldermen should either be abolished or the common council given a concurrent vote on all matters in relation to streets, and that this council petition the legislature, now in session, for such a change in the laws as will prevent such outrageous legislation in the future.

The resolves were declared passed; but upon a yea and nay vote being called for, it was found that they were lost by a vote of 30 nays to 11 yeas.

The order requesting the committee on judiciary to ask the corporation counsel to define the relative powers of both branches of the city council in regard to the streets of this city, both surface and underground, and uses of the streets for any purpose, was passed in concurrence with the board of aldermen.

At the State House, on the 20th ult., the committee on mercantile affairs continued the hearing on the matter of conduits for electrical wires. Professor Cross, of the Institute of Technology, was present to explain, at the request of the telephone companies, the difficulty of placing wires as closely together as would be necessary in underground conduits. A room was fitted up with wires and other apparatus to enable him to demonstrate it. He paid most attention to the effects of induction between wires, showing that when a coil through which a telegraphic current is passing is brought within a distance even of three feet from another coil connected with a telephone receiver, the telegraph current causes distinct sounds to be heard, so that a message could be read at the telephone. With another coil through which was passing a dynamo current about sufficient to produce an ordinary incandescent light, a roar was produced by induction across three feet of air, that one member of the committee compared to a western cyclone.

The effect of induction from one telephone circuit upon another was also shown, the voice of one person talking through an ordinary transmitter being distinctly heard on another circuit running parallel, but not touching it. He said that induction could be prevented by encasing the wires in lead tubes, but that this would give rise to another disturbing effect—that of retardation—since the presence of the mass of metal would act as a drag upon the current passing through the wires. Without going into technicalities, he illustrated the difficulty of placing wires, especially those carrying different kinds of currents, near each other. He said that, however, by a system of twisting two wires together, using one to complete the circuit, instead of the present system of single line circuit, using the ground to complete the circuit, the effect of induction could be reduced to a minimum, at, of course, a much increased cost for the change of system.

In answer to questions by Samuel L. Powers, counsel for the petitioners, he said that the only practical difficulty in the way of placing telephone and telegraph wires underground in the same conduit was the matter of cost. But he was positive that arc light currents could not be placed in the same conduit under any circumstances. If they must go underground it must be by separate conduits. Not only would the induction interfere with the successful working of the other wires, but there would be increased danger to the workmen upon the other wires.

H. N. Shepard appeared in remonstrance for the New England Bell Telephone Co. He began by reviewing the history of the matter of conduits in Boston, saying that the present effort to secure the sole franchise was made by the American Conduit and Construction Co., of which the principal stockholders were Michael Meehan, formerly superintendent of streets, James J. Colman and Frank E. Magullion, liquor dealers. This company owned a patent for making carbonized stone, and was organized with a nominal capital of $1,000,000, which they certified had been paid in as required by law; but a little investigation showed that but $600 in cash had been paid, the balance of $999,400 consisting of "patents and franchises." He then showed that the telephone company was gradually putting all its wires underground in this city. It already has 4½ miles of conduits in the streets of Boston, in which there are 785 miles of wire, with room for 6,300 miles more. About $75,000 has already been spent for this, and $50,000 more will be expended in another year. The method used does not disturb the streets for more than three days in any case, and man-holes are provided at frequent intervals for the purpose of inspection, so that the surface of the streets is not again disturbed. He criticised the action of the board of aldermen in granting the exclusive franchise which they did, and disputed the statement before made by Mr. Powers, that exclusive franchises had been given in other cities for the building of conduits. To support this he read letters from the Brooklyn electric subway commission and similar

bodies in other cities, showing that in no large city is there a conduit holding both arc light and telephone wires, and that in no city has there been granted an exclusive franchise as contemplated here.

Thomas D. Lockwood, an electrician of the telephone company, said that his 20 years of practical experience had led him to the same conclusions as those reached by Professor Cross from a scientific point of view, though he might differ from him in a few details. He showed the difference in the different currents, by stating that taking the strength of a telephone current at one, a telegraph current would be 212, an arc light current 5,308. He argued at length to show that the telephone company was doing its best to put its lines underground, but wanted to do it in its own way, as it is a new subject, and the way must be felt by experiment. He stated that no new wires were being strung overhead in Boston by the company, except in a very few cases.

Ex-councilman H. L. Harding appeared for the Citizen's Association, and stated that the association wished to present a bill providing for placing the wires underground, but in a different way from that proposed.

The hearing was adjourned until the 20th, when D. A. Harrington, engineer of the New England Telephone and Telegraph Co., described the system of conduits now in operation by that company.

J. W. Bennett, of the Erie Telephone & Telegraph Co., stated that in the cities with which he was acquainted there was no system of conduits that worked satisfactorily.

Joseph W. Learish, engineer in the employ of the Western Union, corroborated the statements of Professor Cross relative to induction, and the testimony in reference to the interference of wires.

The committee were given until the 15th inst. to make a report —on which date the committee on mercantile affairs reported a bill for placing electric wires underground. Senators Clark, of Hampshire, Cook, of Essex, and Stevens, of Norfolk and Representative Gill, of Worcester, dissent. The bill gives permission to local authorities to construct general systems of subway conduits through which to conduct all classes of electric wires and cables, and may provide on contract for their construction and maintenance, but no exclusive rights are to be granted. When enough conduit has been built to warrant putting the overhead wires underground, the local authorities may order the change to be made, provided that the wires and cables can be operated in the conduits without material injury to the interests of the persons or corporations operating them, but in no case shall electric light and power wires be put with other electric wires in any conduits without the written assent of all the persons and corporations operating the telegraph and telephone wires in the same conduits. Authority is given to compel the removal of the poles now erected. The local authorities may prescribe the terms on which the conduits shall be used, and may fix the tolls. Refusal to put the wires underground, upon order, is punishable by $500 fine for every offence. Existing rights in conduits already laid are not to be affected.

Meantime the telephone companies are actively engaged in putting down conduits in the streets in which they have obtained the right and privilege so to do, and if not disturbed, will soon have down all they will require for some years to come.

The police signal systems are having a sharp contest in the city for supremacy; the Gamewell, represented by Joseph W. Stover, and the Municipal, represented by John C. Wilson. The board of police, on the 3d inst., opened the bids for the contract for building the signal system on divisions 3, 4, 9 and 15. There were two bids, from the Gamewell system, represented by its president, Joseph W. Stover, and the Municipal system, represented by general manager John C. Wilson. Mr. Wilson's bid was the lowest, and he was awarded the contract. After some further debate the amendment was rejected—7 to 21—and the bill advanced one stage.

New England and the east have experienced the epidemic, now quite general, of trouble with electric light wires. Fire in Fall River, on the evening of the 25th ult., destroyed the plant of the electric station of the Edison company. The company had 4,200 lights on its lines. Guests at the Harvard ball, the social event of the season, were left with a few gas jets and a lamp or two. In Halifax, on the 1st inst., another electric light patrol man, named Geo. Crocker, was killed on the same spot as was Welber on Sunday night, under exactly the same circumstances. He went up a post, threw one of his legs over a cross-piece, when it must have come in contact with the wire. He then clutched the wire with his hands and was killed instantly. Crocker had had considerable experience in the business and it was thought knew all about it.

The electric lighting system is to be introduced into the Charlestown Navy Yard, and the dynamos, wires, lamps and other appurtenances to be used, will be bought outright by the government. The shops and streets will be illuminated with arc lamps, and the offices and residences by the Edison incandescent system. It is expected that the system will be in full running order before the next winter.

BOSTON, May 16th, 1888.

The Alternating Current Discussion at the Chicago Electric Club.—Mr. Elmer A. Sperry on Alternate Current Motors..—Club Notes.—A Gas Explosion.—Difficulty of Running Electric Light Circuits in Chicago.—The Town of Pullman to have an Electric Railway.—The Electric Railway at St. Paul Opened May 10.—Other Railway Notes.—Growth of Electric Motor Business.—The Chicago Telephone Company Hampered by the City Council.—The New Telephone Building.—The Western Gas Association.—Electric Light Men Excluded from a Benevolent Assurance Society.—Electric Light Notes.—The New Thomson-Houston Building.—Reducing Ores by Electricity; Mr. H. B. Slater's Method in Use in a Silver Mine at Leadville.—Professor Elisha Gray's Lectures at the Northwestern University.—Long-lived Incandescent Lamps.—Intense Competition in Electrical Business.—The Western Electric Co. Preparing 200 Arc Lamps for their New York Factory.—The Cushman Telephone Co. about to Commence Operations in Chicago, and in Logansport, Ind.

THE greatest interest is manifested in the series of discussions now before the Chicago Electric Club, on the Continuous Current *vs.* the Alternating Current. The fifth paper was read by George Cutter, of the Thomson-Houston company. The title of the paper the "Continuous Current Limited *vs.* the Alternating Current Unlimited," indicates very nearly the spirit in which Mr. Cutter treated the subject. He found little or no place for the continuous current in the economy of electrical distribution. He entered the lists according to his own declaration as a partisan of a pronounced type and he proved himself a strong champion. He thought the continuous current had served an excellent purpose as a pioneer, but for the future the alternating system was alone desirable and economical. Mr. Leonard, of the Edison company, championed his system warmly in the discussion which followed. Whatever may be said of the merits of the question Mr. Leonard may well feel flattered by the course which the series of papers has followed. Since the reading of the first paper by him all those who have entered the discussion have sought to weaken or support his position. All the arguments have had reference to statements which he made so positively in his treatment of the subject. At the meeting, May 21st, Mr. Elmer A. Sperry read an interesting paper on alternating current motors. Mr. Sperry is a thorough believer in the alternating current, and his topic called forth an interesting discussion. George H. Bliss will present a paper in advocacy of the continuous current system at the first meeting in June. The Electric Club proposes to adopt means for increasing its membership. It is hoped to increase the number of members from 120 to 150 at least. The improvements which are now being made in the rooms will tend to make it more popular as a society, and there is little doubt that the roll of members will soon reach the desired number.

In the latter part of last month an explosion occurred in the basement of the building occupied by the Bell Clothing Co. on State street. The employés of the Arc Light & Power Co. were driving a tube intended for arc light wires under the sidewalk. A gas pipe was struck, the gas which collected in the cellar was ignited by a gas jet. The damage to the windows and stock amounted to several thousand dollars. The explosion serves to illustrate the difficulties which are met with by electric light companies in Chicago. They are not allowed to string wires overhead, and permits for digging up the street are not dealt out with a lavish hand. They frequently are obliged to resort to forcing a tube under a flag walk as in the case mentioned. This is the first accident of the kind, however, which has occurred from this cause in the city. It is understood that the electric light company settled with the clothing house for the damages within two hours after the explosion.

There have been a number of explosions within the last few weeks in the underground conduits. Man-hole covers have been blown off perhaps in a dozen instances. The "terrific force of the explosions," referred to in the daily press, does not raise the man-hole covers over two or three feet from the ground though the papers speak of several miraculous escapes. The city electrician, Professor Barrett explains the explosions in this way: "The gas pipes leak horribly. We must do one or two things; we must insist on air tight conduits or the gas company must cork its pipes so they will not leak and the gas collect in the conduits. Pipes everywhere are badly jointed, and when the ground is thawing everything is saturated with gas. This escaping gas is so plenty that it often must be pumped out before an employé can enter a man-hole to work. We have to open up a system of man-holes every week or two to get ventilated. We have been studying a system of ventilation but can't get a draught through the conduits. There are seven conduits, and I believe they should be under one management. I think the city would be benefited by assuming the construction of a general conduit and by compelling the corporations to use it." It would seem from this statement that the gas companies alone are responsible for the explosions which unquestionably create no little uneasiness.

The Pullman Palace Car Co. is to build an electric road in its substantial town of Pullman. The road will be five miles in length. The overhead system will be employed, and the cars which, of course, will be turned out at the Pullman works will be of ele-

gant design. Mr. Charles Pullman said to the ELECTRICAL ENGINEER representative that it was proposed to push the road rapidly to completion. An electric road in St. Paul was opened May 10th, with appropriate ceremonies. Representatives from Minneapolis were present to extend congratulations. Milwaukee will soon have an electric road six miles in length. There is considerable interest manifested publicly in Chicago in the electric motor. The working of the north side cable road has by no means been satisfactory; and following the rule that misfortunes never come singly, the system has usually broken down at the time when most persons desired to reach the city or wished to return home. This fact has given rise to a general desire among street car men to experiment with other modes of street car propulsion. Thus far the talk of electric street roads in the city amounts to very little; but that there is a general interest in electric roads is true beyond doubt, and the investigation which has thus been encouraged may soon yield something tangible.

There is an increased demand for small motors. The Sprague company has recently installed two 10 h. p. motors and one of half that capacity in the Phœnix building. They are employed to drive three ventilating fans. They run without sparking and are giving perfect satisfaction.

The Chicago Telephone Co. has been in anything but a pleasant situation. The company asked permission of the city council to move its wires so as to accommodate the subscribers who had moved. The city fathers, who oppose the telephone corporation almost to a man, refused to consider the request. Mayor Roche came to the rescue of the company. He gave into the hands of city employés the task of removing the wires, and the cost of the work will be charged to the company. The telephone company claims to have the finest building used as an exchange in the world. It is an elegant structure and all its appointments are of the latest design. The 2,200 wires previously running into the branch exchanges were transferred to headquarters May 12th. The work had been so well planned that connection was not interfered with for over 10 minutes on any wire. Naturally the transfer to the new quarters caused confusion for a few days, but the exchange is now in excellent running order.

The Western Gas Association met in Chicago for three days, beginning May 9th. The only electrical paper was that presented by C. M. Keller, of Columbus, O., "On the Cost of Arc Lights." His company has two 50-light machines. For an all night light the expense was, he said, 20½ cents per night; for a 11 o'clock light the cost was 17½ cents. The members discussed the paper with interest, and it seemed to be the impression of the progressive majority that gas companies in order to hold their own must put in electric light plants.

Those who are interested in electric lighting are somewhat surprised to learn that the Royal League, a secret benevolent insurance company, had a rule declaring all persons who handled electric light apparatus in any way ineligible to membership. As this applies to engineers, electricians and many others, there is considerable dissatisfaction expressed, as it is feared that this sweeping provision may be adopted by other insurance organizations. They rightly consider their occupation as one which cannot be classed as hazardous, and they hold that if a rule is adopted in this regard it should be discriminating, and exclude only those whose work in connection with the electric light is actually attended by risk.

The contract for lighting the Mercantile Library Association building of St. Louis, has been awarded to the Excelsior Electric Light Co., F. W. Horne, western agent, Chicago. The contract calls for 100 arc lights.

In the new building of the Thomson-Houston company, an exhibition plant is to be fitted up showing all the apparatus sold by the company. Dynamos, feeding arc and incandescent lights, and electric motors will be in operation.

H. B. Slater, of Detroit, was recently in Chicago. He spoke of a method he had invented for reducing refractory ores by electricity. The process is said to be employed with success in the iron silver mine at Leadville.

Professor Elisha Gray is delivering a series of non-technical lectures on electricity before the students of the Northwestern University at Evanston. He gives a large number of experiments, in which he is always particularly successful. It will be several months before his telautograph is on the market.

The engineer of the Union League in Chicago, says that of the 1,000 lamps in the club house, between 200 and 300 have had a life of 4,300 hours.

The managers of electrical companies are not complaining of the amount of business which they find, but they do find fault with competition. They say that the intense rivalry is extracting every cent of profit, and that when a company enters into a struggle for a contract its officers must be prepared to install the plant for love and honor.

Two hundred arc lamps, to be used in the factory of the Western Electric Co. in New York, are being manufactured at the company's factory in Chicago.

The Cushman Telephone Co. will commence the first part of next month the work of soliciting subscribers for its Chicago exchange. The Logansport, Ind., exchange will be in operation June 15th.

CHICAGO, May 25, 1888.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall street, New York city.*

WELDING RAILS BY ELECTRICITY.

[93].—My attention has been called to a notice in the May number of your journal, under the caption "Welding Rails by Electricity," some of the statements of which convince me that the author is either totally unacquainted with the subject or has not considered some of its most important details.

The invention referred to in the notice consists in welding the ends of steel rails of ordinary length together, so as to form continuous tracks of one thousand feet of more in length, the energy employed to generate the heat being electrical. It also further consists in providing expansion and contraction joints at the ends of these long lengths to compensate for the varying effects of constantly changing temperatures.

There are several difficulties in the way of such a scheme that seem to me to render it impracticable. First, as is perfectly well known by any one who is conversant with the tempering properties of steel, the joints and adjacent parts of the rail could not be tempered equally with the other parts of the track, on account of the wide gap between the temperatures at which steel will chill or temper and anneal respectively. There would thus remain a soft or annealed portion of metal on each side of the joint, which could not be avoided except by heating and retempering the whole track.

Secondly, as a rail of steel one thousand feet long would contract about one inch and one-half for every ten degrees of drop in temperature, and as the range of temperature from maximum to minimum may be about 140 degrees Fahr. in this latitude, joints would have to be provided at every thousand feet which would allow a contraction of considerably over one foot. Nor is this all, for some means for facilitating the motion of the track due to expansion and contraction would have to be provided, or ruptures in the metal would occur; and it is extremely doubtful whether the tendency of such a rupture to buckle could ever be overcome by any mechanical arrangement. For instance, on a down grade every expansion would tend to force the track a certain length down, while the subsequent contraction would not be strong enough to raise the track to its former position.

There are other difficulties which suggest themselves to those familiar with the subject, such as the inconvenience of repairing worn portions of a track, etc., which render the project at present impracticable. It is hardly necessary to say that it would be practically impossible to make a welded joint in steel rails of several square inches area of section in less than "half a minute." It seems to me that the scheme here proposed is of the same impracticable nature as the recently proposed schemes for heating railway cars by electricity, in which the power for heating is derived from the propulsive power of the train—schemes which the present state of electrical science does not warrant us in saying that they will ever be put into operation with success,

Very truly yours, OTIS K. STUART.

.... IF the use of platinum was carried all the way through in switch-boards and bell connections, it would save a vast deal of money in inspection and give a vast deal of comfort and satisfaction in service.—*R. M. Bailey.*

.... I HAVE kept an accurate record of the current that went into my secondary battery, and the mean of the current that came out of it, during the last twelve months, and I have certainly got an efficiency out of the cells of 80 per cent.—*William H. Preece.*

... MECHANICAL engineers seem to look upon electricity as though it were some formidable rival. I wish they would regard it purely as a means of transmitting force from place to place. The manufacture of the dynamo and motor is purely a mechanical undertaking.—*Magnus Volk.*

ELECTRICAL NEWS AND NOTES.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

ANNUAL MEETING.

THE annual meeting for election of officers and other business, was held Tuesday Evening May 15, at the house of the American Society of Civil Engineers, New York. The President, T. Commerford Martin, calling the meeting to order said :—

It is with much pleasure, fellow members of the Institute, that I greet you on the evening which closes our fourth year. The year which we have just gone through, has seen, I think we may say, a noteworthy increase in the membership, the influence and the reputation of the Institute. We have, I believe, more than doubled our membership. We have had a corresponding increase in our funds, and owing to the larger resources at command, we have been enabled to give greater attention to the editing and publication of our transactions, and have been able to give them a standing which I believe is equal to that of the transactions of any similar scientific society.

The papers which have been brought before us during the past year cover a wide range of subjects, all of which fall mainly within our sphere of consideration. They are, "The Electric Lighting of Passenger Trains," by Mr. G. W. Blodgett; "The Coulomb Meter," by Professor George Forbes; "Electric Street Cars," by Anthony Reckenzaun; "Improvements in Apparatus for Ocean Cabling," by Charles Cuttriss; "Phenomena of Retardation in the Induction Coil," by William Stanley, Jr.; "The Revision of the Patent Laws," by Arthur Steuart; "Electric Energy from Carbon without Heat," by Willard E. Case; "Alternating Current Motors," by Dr. Louis Duncan, and "The Maximum Efficiency of Incandescent Lamps," by Mr. John W. Howell.

The papers were all of them, it may be said, of a high order of merit, and have done much to secure for the Institute the reputation which it now enjoys.

The first business in order this evening is the reception of reports from the officers of the Institute. We shall be glad I think to have first the report of the secretary and then take that of the treasurer, and the reports of the various permanent committees. At this time I think it will be well if I appoint a nominating committee to take in hand the matter of the nomination of officers for the ensuing year. Upon that committee I, therefore, nominate Mr. S. S. Wheeler, Mr. C. A. Terry and Mr. C. O. Mailloux. I will now ask the secretary to give us his report.

SECRETARY'S REPORT.

With the close of the fourth year of the existence of the Institute, your secretary takes pleasure in announcing that the work for which it was organized has been still more actively entered upon since the last annual meeting, and with exceedingly gratifying results. Believing that its past record was of sufficient importance and interest to warrant more general support from all who were interested in electrical science, it was deemed proper that efforts should be made to enlist the aid of all who appreciated the value of such an organization. This policy has been beneficial in various ways. It has made known the existence of the Institute, and gained for it a world-wide reputation. It has enlisted the support of new adherents, and stimulated the attachment of those who were previously associated with it. The additional revenue thus derived has enabled the council to carry out various plans for the general good, and increased the value of membership to distant as well as local friends.

The plan of holding more frequent meetings, undertaken last year, has been continued more systematically, and all have been well attended. The value of the papers presented, and the discussions which followed, are familiar to all by reason of their monthly publication and distribution. The transactions of the Institute have also been very generally printed by electrical journals at home and abroad. In order to add to the value of the Institute's publications, a classified index was begun in December of all articles of importance on electricity, appearing in technical journals, published in the English language. This index is appended every month to the issue of the Transactions. Some idea of its scope and of the work involved may be formed when it is stated that the index during its first six months of compilation has included under the various heads upwards of 2,500 distinct articles, for which have been given nearly 4,000 references, accompanied by over 500 explanatory and critical notes. The immediate appreciation of this work on every hand is a sufficient warrant and reward for its execution. Such an index, if existing to-day, of early periodical literature on electricity would be simply invaluable, as those who have occasion to make searches or are investigating in any branch can testify; and the secretary believes that by assuming the task at this time, the Institute will be found in a very few years to have done a work of inestimable importance. It is now proposed to extend the index so as to include all electrical books as they appear. The bibliography of electricity will then be rendered complete.

The Institute has doubled its numerical strength since the last annual meeting, besides reclaiming a good percentage of original members who had become lukewarm in their support. The increased revenue has been devoted to such purposes as would result in satisfying every member that he was receiving a fair equivalent for his share of the amount expended.

The project of providing permanent quarters, which has been referred to in three previous annual reports, has been given careful consideration during the past year by the council and its committee, as well as by the officers individually. Although greater progress might have been made, at the risk of abandoning the more important work of the Institute, it was deemed wise to continue for the present upon the line of policy which is now being pursued. The business affairs of the Institute and its accumulating literature made it necessary, however, that office quarters should be secured, and a suitable room has been leased and furnished for this purpose in Temple Court, No. 5 Beekman street.

The cordial relations which have existed since its organization between the Institute and the American Society of Civil Engineers still continue, and the meetings of the Institute will be held at the house of the latter, by courtesy of the board of managers, during the coming year, at the discretion of council.

There have been 182 associate members elected during the past year, of whom 166 have qualified by paying their entrance fees and annual dues. Four have resigned, one has died, one has been dropped from the roll, and one placed upon the suspended list. The total number of members and associates is 322, of whom 267 have paid up in full to date, seven are in arrears for the present year, twelve for two years, and thirty-six for three years. There has been an improvement in the delinquent list, by the collection of $387.50 during the year, but many of those who remain upon it have lost all interest in the work of the Institute. Others have met with financial difficulties which may yet be overcome.

The secretary takes pleasure in acknowledging the receipt of the following gifts from friends of the Institute:

From Mr. Edward P. Thompson, a carpet for the office of the Institute.

From Mr. T. C. Martin, $25 cash toward furnishing the same.

From Mr. Charles Colné, a set of Patent Office Reports.

From the Consolidated Telegraph and Electrical Subway Company, a bound volume of photographic views of the subways as constructed in New York city.

From Mr. Emile Berliner, a working model of his "Molecularium."

From Mr. Wm. H. Sawyer, files of the London *Electrician*, London *Electrical Review*, and New York ELECTRICIAN and ELECTRICAL ENGINEER.

Respectfully submitted,

RALPH W. POPE, *Secretary*.

NEW YORK, May 15, 1888.

The secretary's report was accepted and ordered on file.

The secretary then read the treasurer's report as follows:

TREASURER'S REPORT.

George M. Phelps, Jr., in Account with American Institute of Electrical Engineers.

Dr.

Receipts from May 21, 1887 to May 15, 1888, as per remittances from secretary		$3,871.02

Cr.

Payments from May 21, 1887 to May 15, 1888, on warrants from secretary (Nos. 1 to 63)	$3,468.58	
Balance to new account.................... ...	402.44	3,871.02
Balance on hand May 15, 1888..................		$402.44

NOTE.—The actual receipts and payments are each $100 less than above figures, that sum having been advanced for a contingent expense which proved not required when the amount was refunded.

Building Fund.

Amount paid on subscriptions and now in treas urer's hands..........................	$450.00

GEO. M. PHELPS, JR., *Treasurer*.

The treasurer's report as read was accepted and ordered on file.

At the suggestion of Mr. Phelps that an auditing committee examine the treasurer's report and vouchers, the President appointed Mr. G. A. Hamilton and Mr. F. W. Jones as such committee.

Capt. Michaelis—reporting for the wire gauge committee, said:—The committee have been rather inactive. I apologize to the Institute, but for various reasons nothing has been done lately in the matter.

After a brief consideration of the subject, the wire gauge committee was, on motion, discharged—the general view seeming to be that it would not be advisable to undertake any further action.

The report of the committee on permanent quarters, was given orally by Mr. Phelps, chairman, as follows:—

The portion of the secretary's report relating to the quarters of

the Institute may fairly be considered as the report of the committee. It states that the arrangement reported has been approved by the council, and the committee. There has been no material change in the project of raising a fund within the last few months. The state of the matter was published in all the journals. There was a subscription amounting to about $5,000, and of which, as the treasurer's report shows, exactly $450 has been collected. The committee did not prosecute to any great extent the solicitation of donations outside of the Institute, and the sum reached in the subscription list seemed to be pretty nearly the limit to be expected within the membership. But for various reasons the project of getting a house for ourselves during the past year has turned out to be impracticable, and the committee have joined with the council and the officers in recommending the hiring of the room in Temple Court, which will serve the secretary for his regular duties, and afford a convenient reading room, and also space enough for council meetings, which can be held conveniently down-town. The committee prepared no written report, relying upon the secretary's statement on the subject in his report.

The report of the committee on permanent quarters was accepted.

The President—There being no further committees to report, we shall be glad to hear from the nominating committee. While the nominating committee is coming, however, I would call attention to the fact that the vacancies which occur to night and which are to be filled are in the presidency, in the vice-presidencies of Dr. Green, Professor Elihu Thomson and Mr. George C. Maynard, and in the managerships of Mr. Charles L. Buckingham, Mr. David Brooks and Mr. E. P. Thompson. In the case of vice-president Elihu Thomson, and in that of Mr. E. P. Thompson, who were elected by the council to fill unexpired terms, I may say that both those gentlemen are eligible to reelection to like places.

Pending the arrival of the nominating committee, I would like to call your attention to the programme which we have before us for to-morrow. It is one of a very interesting character, and I have no doubt that the attendance will be large, and that the discussions will be interesting and valuable.

We have received the following courteous invitation addressed to the secretary:

RALPH W. POPE, ESQ.

Dear Sir:—On behalf of the Electric Club, I take pleasure in extending the courtesies of the Club House, 17 E. 22d street to the members of your association during the present week. As a matter of special interest, the Edison improved phonograph can now be seen and tested in the parlors of the club. Visitors from your association will kindly mention this invitation to the clerk of the club, and they will be promptly admitted at any time between 8 A. M. and 12 o'clock midnight.

Very respectfully yours,

CHARLES W. PRICE, *Secretary*.

I have no doubt that such of us as are not members of the club will be very happy to accept the invitation.

Mr. Phelps—In view of so courteous an invitation, I think it would be proper to accept it by vote and to extend the thanks of the Institute. I therefore move that the invitation be gratefully accepted.

The motion was seconded by Mr. Wetzler, and voted unanimously.

Mr. G. M. Phelps, Jr.—I hope that all the members who have not made themselves at home at the club will do so. They are quite sure to find it pleasurable in many ways.

The nominating committee presented its report.

Mr. S. S. Wheeler, chairman, said:—In presenting these nominations on behalf of the committee, it seems to be a good opportunity to call attention to the feeling that prevails in the Institute in regard to getting the services of men who will give some of their time and energies to the work, and I would say that all these men have been selected in reference to that. The nominations are:

For president, Edward Weston.

For vice-presidents, Elihu Thomson, F. R. Upton and T. C. Martin.

For managers, Charles Cuttriss, George B. Prescott, Jr., William Maver, Jr. and T. D. Lockwood.

For secretary, R. W. Pope.

For treasurer, G. M. Phelps, Jr.

Capt. Michaelis—As I have heard no other nominations made, I move that the secretary be authorized to cast a ballot for the individuals named by the committee as the vote or ballot of the society.

The motion was carried unanimously.

The President—Will Mr. Vansize and Mr. Thompson please act as tellers to receive the ballots?

Mr. Vansize—Your committee, to whom was assigned the duty of scrutinizing the ballot for officers for the ensuing year, have to report that the ballot was cast in accordance with the motion passed, and herewith hand you the result of the ballot.

The President then announced that the persons named by the nominating committee for the respective offices were elected.

The President—Is there no other business to be brought before us this evening?

Capt. O. E. Michaelis—At the last annual meeting the subject of certain amendments to the constitution was considered, and the matter was referred to the council. As under the constitutional provision such amendments can only be considered at the annual meeting, or at a meeting called for the purpose, I would like to inquire whether it might not be advisable in the course of this meeting, either to-night or to-morrow, that this subject, a very important one certainly, be brought forward for consideration.

The President—Since no action has been taken I presume a new motion would have the effect of vitalizing that subject.

Capt. Michaelis—I move, then, that the council be requested to make such reports on the amendments to the constitution as they deem advisable to the meeting to-morrow.

The motion was seconded.

Mr. Phelps—If you will permit me, Mr. Chairman, I believe that as a matter of fact the council have given no attention to preparing amendments to the constitution. I suppose it would be quite impracticable between now and any session we may have to-morrow to put in proper shape any general revision of the constitution or rules, and even any particular revision. Such an attempt would necessarily occupy a great deal of time, and to-morrow, when we have a great many papers, there will scarcely be time to act upon the subject with due deliberation.

Mr. Mailloux—There is one matter particularly which I think should receive our attention in revising the rules, and that is the manner of conducting elections. I do not approve of our present method of electing officers. The annual meetings are never fully attended, and under our present procedure it is impossible for us to get anything like an expression of general sentiment among the members. It seems very strange indeed that some forty or fifty members should have to do the electing for over three hundred, and I think we ought to adopt some measures similar to those which are followed in other engineering societies. The present plan brings the selection to a very narrow limit, and may engender unpleasant feeling some time. If a more general participation in nominations could be secured by a change of method it would be more satisfactory.

The President—It is not the desire of the chair to participate at any length in a discussion which is certainly likely to be valuable, but I think it my duty to point out that Mr. Mailloux, or any other member, has the opportunity to-night of presenting resolutions which may entirely revolutionize our course of procedure, and which may be adopted to-morrow. Rule No. 8 reads: "These rules may be amended at any regular meeting by a two-thirds vote of the members present, provided that written notice of the proposed amendment shall have been given at a previous meeting." This meeting to-night is entirely separate from that of to-morrow. Any notice, therefore, given to-night could be acted upon to-morrow. The matter of elections is always a difficult one in a body like our own. Mr. Mailloux, who was one of our charter members, and who is familiar with our procedure from the first, may remember that at one time we had a method of electing by ballots distributed all over the country, a practice which is followed by societies similar to our own. At that time I had the misfortune to be acting as secretary, and it added very much to the burden of life to get those ballots out two or three weeks ahead and get them back three or four weeks behind, and having members object to my ticket, and others asking who got that ticket up. Now, to-night we come here, I think we may say without any caucusing. We do not come altogether unprepared; it would not be right to do so. We must cast a glance around the field of our membership and see those who are eligible by nearness to us to participate somewhat actively in our work. There are certain gentlemen we would be very glad indeed to have in the most prominent offices of the Institute if they could only be near us, and that is the feeling that they have. It was open to-night to any gentleman, when the nominating committee's report was presented to name any candidate he chose, and had that candidate been the choice of the meeting he would have been elected. And I think by our course of proceeding to-night we get as near to the real wish of the Institute as we could in any other way. At the same time Mr. Mailloux's remarks have weight and pertinence.

Capt. Michaelis withdrew his motion for a report from the council.

The President—There was another subject before our last meeting which was important, and that was the matter of junior membership, on which we arrived at no conclusion.

Mr. Phelps—I think that was what led to the action which Capt. Michaelis recalls. That subject was discussed at great length.

Capt. Michaelis—When a society is young, it requires very little constitution. Its affairs and its rules are simple and no conflicts can arise. But I was struck this evening by the very delicate duty that was imposed upon the president of appointing a nominating committee. That is a duty which I think he should not be compelled to perform at all. You can easily imagine cases where it would be exceedingly delicate and unpleasant. We might want a gentleman renominated to the position, and he

might be not unwilling to accept the office, and the whole Institute might wish the re-election. I think the selection of a nominating committee should not be in the hands of the president at all. They should represent the Institute at large. Now, some provision ought to be made in regard to that. Think how dangerous a power lies in so small a number of members as are usually present. We have three or four hundred members I believe. Very few members might be present at a meeting and somebody might present amendments to the constitution changing the entire policy and course of the society, and the other members would have no recourse whatsoever. There was no objection to that formerly, but as we grow we find that our constitution does require enlargement, amendment and possibly, in certain respects, restriction. I think it is really a very important matter. While the Institute is young and is in a measure local, I think the officers ought to be taken from the men who will work for it no matter what their age or previous condition of servitude may be. I do not think that that holds good as our institution becomes nationalized. That has been the course that has been followed by all the other large and kindred societies. In their infancy they were local. As we become nationalized we could well afford to return to the letter ballot and give each member of the society an opportunity of expressing his wish with regard to its policy and its officers. I hardly think that time has yet come, but I have no doubt it will in the near future. Something ought to be done to relieve the president of this delicate and possibly very disagreeable duty of nominating a committee who are to report, possibly, on his own successors or himself, or his friends. I do not think any harm has been done. I think the committee has reported an excellent ticket. I do not think the nominating committee ought to be officers of the Institute.

Mr. Phelps—I think, Sir, that neither the constitution nor the rules deal in any way with the question of how nominations are to be made, so that the remedy for this state of things would be very simple. It would be merely that at any time before an election a nominating committee should be elected. But after all a nominating committee is not an authoritative body at all. As the president has very clearly pointed out, the election is in the hands of the gentlemen who vote. Anyone may make any nomination that pleases him.

Mr. C. A. Terry—I think the difficulty we all labor under is this, that the nominating committee having brought in a list of nominations under the present custom of the society no one feels at liberty without treading on some one's toes very severely, to speak of any other person. The point on which there could arise any difference of opinion at any time, is apparently the matter of the presidency. If we could nominate a president by first having a general nomination on the part of the members by ballot, letting the few leading names which are brought in as the result of that ballot be understood to be the candidates, as they doubtless would, that would relieve us and would relieve the nominating board of all question and all disagreeable duties in that connection; and then the other officers I think would follow on without any question as regards the members of the Institute. But in the case of a nominating board there might be two in favor of one person and one opposed, or there might be three in favor of three different individuals, and under the present custom they could bring in but one name, yet if three names could have been brought in it would leave the way open to a much pleasanter and easier, and probably a more satisfactory election. I think the easier and more feasible way for our Institute would be to have a general nomination for the office of president, and then select from the two who stood highest.

Mr. R. W. Pope—Could not these points be covered to a certain extent, especially the one brought up by Capt. Michaelis, by the nomination of a committee to-night, or the election of a committee to-night to serve the ensuing year? It is not provided for in the constitution. There is no nominating committee provided for. But if this meeting to-night should select a nominating committee of three or five or any other number, and independent of the council, that committee would be in force and ready to act previous to the next election, and relieve the president from the delicacy of appointing a committee where he might perhaps be himself a candidate for the office.

The President—It seems to me gentlemen, that out of the various suggestions that we have received some better line of policy might be selected or devised. At the same time I would like to point out that under the old method which prevailed, the council was practically a self-electing and self-continuing body. By selecting a ballot to be sent out in advance to the members it partly chose its own successors. Now, to-night, the election is open to all. Under the old method it was not open to all. It was only open to such as the council chose to select for the ticket.

Capt. Michaelis—I think I will renew the motion I made last year. It is a delicate matter and I think we ought to hasten slowly and not prepare something that we may be sorry for, if we pass it now. I move you now that this subject of amendments to the constitution be again referred to the council, and that they be instructed to make a report at some special meeting to be called by the president next fall or winter.

Capt. Michaelis' motion was seconded and carried.

Mr. Higgins—I should like to ask if it would not be possible to conduct an election somewhat in this wise: To have the ballots sent in by mail from all members, and at a certain time before each meeting to have the ballot box closed as it were, and all the ballots counted, and of the two members receiving the highest number of votes, and in the case of managers, etc., the officers receiving the highest number be elected at the regular annual meeting by those present. That would leave the choice divided between the whole Institute and those present, leaving the responsibility mainly, of course, with those present, but at the same time leaving the general choice open to the whole Institute.

The President—Gentlemen, there is no motion now before us. I think there is no objection to the fullest and freest discussion of this question. One of these days it is going to be very vital to the prosperity of the Institute. At the present time I think we have a common feeling with regard to the question, but it is well to look ahead and avoid all possible opportunities of dissension. For that reason I do not feel like checking the discussion, although we have no formal motion. On the other hand, should there be no desire to continue it, a motion to adjourn is in order.

A member suggested, as a method of making nominations, that a circular be sent to each member containing a set of questions, such as, "name your choice for president, vice-president," etc., with blanks for the answers after it; those questions and answers to be assorted by the secretary, and the number of votes to each person for each office tabulated; then, say the three highest of each office to be put in nomination.

Mr. G. B. Prescott, Jr.—I think a society in this stage is very much in the condition of a school-boy who is continually outgrowing his clothes. His parents, of course, do not want to renew his clothing any oftener than they can help, for usually it is an expensive operation. While there is no doubt that this society is growing, and has already changed its clothes in the shape of rules or regulations once or twice, I think that these rules as they are at present are quite sufficient to last another year, and during that time we may progress so far that we may have to change again anyway, and as we can get along with our clothes as they are, I think we had better let the school-boy stay as he is.

Mr. R. W. Pope—This question of amending the constitution has always been up at about every meeting of every society that I was ever connected with, and I agree with the last gentleman who spoke as to the impossibility of making rules that will suit for all time. The most important matter that comes before us now is in regard to elections, and if we can provide for the nominations satisfactorily I do not see any objection to the rules as they stand, although they are crude in many respects. One of the defects we encounter in the mailed ballot is that the local members are not only fully conversant with the names and claims of the candidates and with their activity in the interests of the Institute, while those members who are at distant points would find it very difficult to acquire such knowledge, and must also be less familiar with the workings of the machinery on the spot. I believe that if we can provide an unbiased nominating committee who shall hold office from year to year, that is, as I suggested before, if we appoint one to-night from the body of this meeting who are not officers or members of the council, who shall hold office until next year, it would meet one of the objections that have been brought up as to the delicacy of the task of the nominating committee appointed by the president. This is a regular annual meeting, and it is very proper that it should be done at this time. The committee will have no active work to do, and they can begin say three months before the next annual meeting and canvass and be prepared to present a good ticket.

Mr. Vansize—The only objection I see to the proposed plan of Mr. Pope is that it would cut off the members who might become connected with the society during the ensuing year from the participation in the nomination of officers. It seems to me that the solution of the difficulty could be had in this way—that at the next annual meeting we take an informal ballot, and of those individuals receiving, say the three highest numbers of ballots, we take the first two and select from them a president, or, say, the first three, and in that way we might proceed with nominations for the other officers. In that way I think that the difficulties which beset the president and the nominating committee could be obviated, as well as the objections to the ballot by mail. It would be very desirable if the matter could be discussed in the technical journals which circulate throughout our membership, and it might be well to put this matter in the form of a resolution which could be referred to the council as tending to influence their action under the resolution proposed by Capt. Michaelis. For instance, we might make a resolution requesting the council to consider the feasibility of the plan which I have tried to outline.

Mr. Phelps—Since we are falling into a discussion without a motion, which, however, may be very useful, I would like to say a word or two more. Our rules simply provide, I believe, that the election shall be by ballot; that is as far as the rules or the constitution take cognizance of the procedure of elections. Now, why need we have a nominating committee at all? Why may we not simply come here on the night of election with an open field for any member to make any nomination whatsoever? There will naturally be—there always has been, and I suppose always

will be—in such societies more or less preparation in the way of members getting together and discussing the election of this, that, or the other person. Now, there is an absolutely free chance for all to make any individual effort, or any combined effort, to nominate any one whomsoever. Our rules as they stand offer no difficulty to the utmost freedom of action in that regard, and I think if to-night we had no nominating committee whatsoever that we should have elected a satisfactory board which I think now we have done, and very likely it would be much the same board. It does not seem to me that we need any particular action in respect to our rules on this subject. If we elect a nominating committee it would perhaps have even a more formal effect and be more of a deterrent of other nominations than the more informal method of appointing a nominating committee at the meeting simply for the purpose of having a ticket presented. It often happens in other bodies that tickets grow up spontaneously. Sometimes there will be two tickets hardly distinguishable from each other, one nomination or two being different from the nominations on the other ticket. But in the absence of any machinery for nominations, I think they would be brought before us by spontaneous combinations of the members.

Mr. Mailloux—I cordially approve of what Mr. Phelps has said, and while I feel that the nominating committee as such has no *raison d' etre,* and that it is an unpleasant complication of machinery, that it is not necessary for any material change in the constitution to be introduced that we may find the remedy. I think, however, that Mr. Phelps will find that he is really corroborating what Mr. Vansize said before him, and I would say that if Mr. Vansize will put his proposal in the form of a motion I shall be glad to second it, because it seems to me that he has presented to us what appears to be the most agreeable and adequate solution of any that have been suggested this evening.

Mr. Phelps—If you will pardon me, one word more. I agree exactly with Mr. Mailloux's desire, but the rules take no cognizance whatever of methods of nomination. It would have been perfectly open to us to-night, when the order of elections came—it would have been perfectly competent—for any gentleman to move an informal ballot—that may be done next year—any time—and to move as many informal ballots as may be desired to get at this very point. It does not require any action to accomplish that.

Capt. Michaelis—It appears to me that this discussion is very germane to the resolution that we have just passed. I think, however, that while it is very pleasant to exchange our views and get at the gist of these things, I would recommend that these gentlemen who have made, some of them, very happy suggestions, follow the resolutions and submit them to the council, who have now full power to act in the matter. In regard to the plan that has been last proposed I want to say one word. We have a national characteristic, and it holds good in politics of the state and in politics of societies. There should be no taxation without representation. Now, that is the American principle, and it will be carried out everywhere. You cannot restrict it. I am here as a granger member of the Institute. The granger members are in the vast majority, and they have a great interest in the Institute. And while they do not as yet care to vote, I fully recognize the difficulties that the president has suggested from past experience, and I believe that the time has not yet come when we should again revert to the letter ballot which, after all, is the only fair mode of election. But I think that time has not yet come. But what you want is to get at the views of this great majority of our members—of our grangers. The only way that remains is this nominating committee. I think that this nominating committee ought to be elected so long in advance that they can by their own effort find out what the sentiment of the great mass of the membership is in regard to its head, and I think a nominating committee at present can arrive better at the views of the members than a spontaneous expression of opinion at an annual meeting attended by a limited number. I think the council in its wisdom should formulate some way of electing or appointing a nominating committee that should represent the different sections of the country, say a committee of five, and that they should take the trouble to find out the views of members. Let their report be considered the regular ticket. That ticket would come before the Institute with the endorsement of regularity and as reflecting the views of the members, and of course the chances are that it would be elected. It usually is.

Dr. O. A. Moses—Mr. President, it is a well accepted maxim in the management of large political bodies that the preparation of business, the suggestion of it, should be confided to a few, the adopting of it to many, and the execution to a few. Now, in a society of this kind, which numbers among its members many extramural ones, it seems to me that the views of those who are beyond us should be heard, particularly in these days of rapid transmission of thought. It would seem to me, though I beg to state that my view is after all the digest of the many views I have heard expressed, that as good a method as any to pursue would be for the nominating committee, of a few, to be appointed, whose duties should be to a certain extent to carry out the traditions and policies of those who are for the time being in power. Every society has, or should have a policy. That policy should be a definite one, calculated for the general advancement of the interests represented by the members of the society, and no one is supposed to better understand those interests than the head of the society at the time. He is going out of office, and he can in a certain way delegate his powers to a larger number than himself who will consider his views, and those, perhaps, of the council as expressing the best policy of the society. I say that as a reason for the appointment of a nominating committee. That nominating committee should consider names well selected. While they are deliberating upon them, which might be during the course of one or two hours at the meeting held for that purpose, those who feel that they have friends who should be represented in the councils of the society should be at liberty to put in what is called an opposition ticket, the object being not to oppose, but to give an opportunity for those who think there are others well adapted to be represented in the councils of the society an opportunity to be there as representatives. Now, that is not all. The time for the selection should not be immediate, because those who are present represent as a rule a small number, a small fraction of the society. A certain time should be allowed to elapse, say thirty days, before a final vote is taken upon those nominations. There are two tickets, then, always in the field, one the regular nomination and the other a ticket of opposition, by courtesy, perhaps, but still another ticket in the field. It is very true that the regular ticket will generally be elected, but at the same time it gives members an opportunity, in case there is a good reason, for the representation of certain persons on the board. Then there is the great advantage that there are two tickets in the field.

Mr. R. W. Pope—I might say in connection with the remarks of the gentleman who has just spoken, that it has been the purpose of the council to make the Institute of the same value to members outside of New York as to those who are in this vicinity, and that is the policy we propose to carry out. How shall the outside members be enabled to participate in the election with the same degree of satisfaction as those who are able to attend the meeting? I presume that much can be learned from the proceedings of other societies in this respect, but I am not able to say just how. In regard to the method proposed by Mr. Vansize, I have known of a similar plan being adopted in other societies and it has worked very satisfactorily.

The President—Just casting a glance casually over the council as it will be constituted during the coming year, I find that, beside the secretary and treasurer, the country members will have a majority in the board, and it should be so. Our constituency is far larger outside of New York than it is within, and I may say that we have almost as large a constituency in the four quarters of the globe as we have within our own city. This organization is not only national but international.

Gentlemen, we have before us a very interesting programme for to morrow. I trust the attendance will be large, and I hope the discussions will be entered upon with zest, and will be valuable and instructive. I trust that every opportunity will be met on the part of members to be in attendance, and I take the pleasure of extending on behalf of the council an invitation to all such gentlemen as may not be members, who are interested in our work, to be present, and we shall be very glad to have members bring their friends so that they may see our work and judge of its extent and value.

The auditing committee has presented its report, which says:

"Your auditing committee has examined the accounts of the treasurer and secretary, as submitted to them to-day, and find them correct."

It is signed George A. Hamilton, F. W. Jones

The meeting then adjourned.

GENERAL MEETING—WEDNESDAY, MAY 16.

The meeting was called to order at 10.30 A.M. by Mr. T. C. Martin, vice-president. Mr. Edward Weston, the president elect, was unable to be present at the opening of the session, being kept at home by illness.

The Chairman—As you are aware, gentlemen, Mr. Edward Weston was elected president of the Institute last night. I have been informed that he is not at all well, and that it is possible that his illness, while it may not wholly prevent his attendance, may delay his arrival here this morning. I think it would be well, however, if we were to proceed immediately with our programme, and I will therefore present, as first upon the programme, the paper by Mr. P. B. Delany on the "Protection of the Human Body from Dangerous Currents;" and as I have promised Mr. Delany to read the paper for him, I will ask Professor Anthony if he will preside while I do so. (For Mr. Delany's paper see p. 244.)

DISCUSSION.

Mr. G. M. Phelps, Jr.—I suppose it will be somewhat difficult to bring the merit of the proposed protection to the test of trial by linemen, or by other persons. Probably there will be few investigators enthusiastic enough in determining the possibilities of

this protection to submit their persons to a test. But unless electricians share the sensibilities of the Anti-Vivisection Society, a great deal might be learned as to the efficacy of the means of protection suggested by Mr. Delany by judicious experiments upon animals. I suppose there will be an opportunity to get an abundant supply of dogs of various sorts the latter part of the summer. I make the suggestion as pointing out a method of testing the efficacy of this means of protection. I am quite serious about it. I can see no reason why very satisfactory tests might not be applied to various animals, and some of the physiological questions implied in Mr. Delany's paper be determined to a great extent.

Specimens of the protectors were handed around the room for the inspection of members.

Mr. R. W. Pope—Mr. President, one of the difficulties encountered in the practical application of a safeguard, according to my investigations, has been the difficulty in enforcing its use amongst the very men whom it is intended to protect. I have heard it stated that miners were averse to carrying safety lamps, and we all know that there are insulated pliers now on the market, and that india-rubber gloves when perfect serve as a protection; yet men go out on their daily duties without taking even these precautions, and consequently we need something more than the invention of a device that will perform its duty in order to save lives. If men are so careless and regardless of dangers as to go out on their duties without preparing against them, I do not see how we can do anything to wholly prevent accidents.

Mr. J. Wetzler—In looking at the question from another point of view, it strikes me that the question which is involved in the fatality of an electric shock depends as much on the electric work done upon the body as upon the potential. Let us take, for instance, the case of a man struck by lightning. We frequently hear of men having been struck and surviving. Here, without question, the potential must be at least many hundred thousand volts. Yet, on the other hand, we see a man touching a wire of 1,500 or 2,000 volts and being killed. In one case we have an enormous potential, but an exceedingly small current; in the other case a small potential, comparatively, but a large current; yet in the latter case the electric work far exceeds that of the lightning stroke, and the man's death ensues. Therefore I should say that the question involves the electric work done upon the human body as well as the potential; and if by means of such an apparatus the work done in the human body can be decreased, I think it would have in that sense some value; that is, if you could shunt a large part of current a man's life might be saved.

Doctor Vander Weyde—We have lately seen in the electrical journals assertions about the voltage that people could stand without injury. It has been stated that a thousand volts could with perfect impunity be taken. But those writers forget that there are two elements to be considered—the potential and the quantity as stated by Mr. Wetzler. When we have a great potential, as in a friction electrical machine, we may have, as Professor Mayer in Hoboken lately showed, many thousand volts potential but no quantity. It will jump easily a distance, but the quantity transmitted is very small, so that it is harmless. But when we take the other extreme, larger quantity or a great number of amperes, it is different. We find that in the thermo-electric pile there is not electromotive force sufficient to penetrate the skin. There is not enough electromotive force even to pass through the liquids of the body. In the galvanic battery we have electromotive force if we use a sufficient number of elements, and we have quantity if our cells are large enough. There we may have a shock, and a battery of that kind, as large as Sir Humphrey Davy used of some four thousand elements may be fatal to an experimenter. It is the relation between the two. There must be a sufficient number of volts and a sufficient number of amperes, both, in order to destroy life. That is the case of lightning. Usually lightning is fatal, because there is sufficient quantity, and at the same time there is electromotive force, as we see by the enormous length of a stroke of lightning. So it is with dynamos; when the electromotive force is combined with sufficient quantity then it becomes dangerous; but I want to impress upon all that electromotive force alone, without quantity, is harmless, and so the heavy currents alone are harmless. It is the combination of the two in which lies the danger.

Professor Elihu Thomson—I quite agree with Dr. Vander Weyde in the opinion that it is not a question of volts or current alone which determines the fatality of a shock. It is quite possible, no doubt, to take a charge from the human body equal to many thousands of volts. One may mount an insulating stool and be charged to a potential of ten or fifteen inches of striking distance and have it discharged from him without the slightest inconvenience—with no more of inconvenience than would result from the discharge through his body of a very small Leyden jar. I have had that experience, and I can testify, that even though such a discharge as that goes directly across the body of a person it has no harmful effects other than a very slight shock, causing a twitching of the arm. In all cases of dangerous shock it seems to me we must have a resistance so low as to permit the volts to send a current of a certain volume through the system. If that current is not attained, it is doubtful whether harmful results will follow. If that current is attained, the harmful results may follow. If we could imagine a man constituted so as to have not more than an ohm resistance, he might, it is conceivable, be killed by a very small voltage, between any two portions of his body, between which are situated vital nerves, nerves whose action is required to keep up the functions of the respiratory organs or the heart. The human subject undoubtedly differs very greatly in resistance at different times, and a fatal shock may be obtained in one case at one time which would not be obtained by the same subject at another time with equal volts, much depending on the moisture of the skin, and probably the amount of salty matter in the blood. The layer of fat which exists underneath the skin acts as a sort of insulator. All these things will have an influence. We have reason to believe, moreover that susceptibility varies very greatly in different persons. I quite agree, also, with Mr. Phelps in the necessity of some really scientific investigations tending to clear up this question. Those investigations, I think, could be carried on with the lower animals, and very valuable data arrived at, as to the passage of the current in certain directions through the body; for example, whether the current in its passing includes, say, the pneumo-gastric nerve, which, if it does not act is sure death every time. The heart must beat in order that life be sustained, and death will occur from heart failure if the heart is not kept beating. If the respiratory organs fail in like manner—if, in other words, the nerves controlling the respiratory functions have their vitality exhausted, that will also be a cause of death. The whole organism depends, I think, upon the nervous system and it is also a possibility that such a thing as nervous polarization may occur. The molecules constituting the nerve fibres may become set or polarized, so that the brain's excitation cannot reverse them or cannot bring them back to a normal condition. That idea has been put forward as a suggestion in regard to recovering—whether it would be likely that a discharge passed in an opposite direction would, as it were, depolarize the nerves and assist recovery, followed by artificial respiration and other means at command. It has been stated, I think, by D'Arsonval that in his opinion the alternating current is not so apt to produce fatal results as the direct current, and particularly direct currents in the nature of sudden discharges or shocks similar to lightning discharges; a large volume of current sent through in intermittent impulses or sent through in one impulse of considerable power. He, I believe, holds to the opinion that in cases of injury by alternating currents resuscitation may be effected, in many cases, by artificial respiration. If this is the true state of the case, it would seem that polarization had something to do with it—polarization of the nerve structure which is prevented by the fact that the alternating currents are continually reversed. The fact also is certainly true that cases of very severe injury are known, where men have been subjected to a very high potential current and all the evidences of the passage of a heavy current through their bodies have been found, and the men have not suffered any great inconvenience other than burning of the hands, so that it would seem as though a critical condition in some cases existed which was not present in others. Whether the person himself has any extra power of resistance or whether his nervous system is so toned up as to be capable of recovering after he has been partially injured, is a question which would naturally arise in connection with this case. I cannot agree that it is a question of one volt more or less whether a man is killed or not, I think the time element is probably the most important of all. There are cases in which men have been struck by lightning, and as you all know have recovered. Discharges of potential of millions of volts have passed through their bodies and they have recovered, and in such cases the discharge was undoubtedly a sudden one, and the current passing must have been very considerable. I cannot regard a lightning flash as an example of a small current. The heating effects which are present in such cases are sufficient to show that the current may rise to very many hundreds of amperes. For example, if a lightning flash will deflagrate a small iron wire in a very small fraction of a second, it means that current, not volts, has done the work, and not only that, but a very large current. It may have existed for but a short time, but it certainly did exist, and the very suddenness of the action is in favor of very high current flowing. We have numerous instances of telegraph and telephone wires melted and other small wires melted by the electric discharge from the clouds, and when we consider the conditions we must see that the current is large. We have only to look at a lightning discharge to see that it may appear to us as thick, sometimes, as a telegraph pole. That, if it means anything, means a body of vapor highly heated, of some considerable area. But lightning discharges, according to my observation, are not always single and alone. They are sometimes repeated half a dozen times down the same path, and it is not to be wondered at that a man receiving, say, a discharge of half a dozen flashes down the same path in rapid succession might be killed, whereas a man receiving one flash, might escape. I have noted that fact by simply keeping my head going during a thunder storm and keeping my eyes fixed in one direction, so as to catch the flashes, and they arrange themselves in parallel lines, oftentimes. I have counted as many as six in that way, very quickly following each other.

Dr. Vander Weyde—I had an opportunity some twenty years ago of making experiments upon the conditions of different persons in regard to heavy shocks, when I was professor in the Cooper Institute. We had a Rhumkorff coil which made sparks at twelve inches. I attempted to increase the length of sparks by some improvements, by taking away all possible edges on the binding posts, and I increased the spark to 16 inches. In making those experiments I was a few times actually knocked down—not exactly knocked down—but I had to *sit down*; I could not help myself. I spoke of it to Dr. Jerome Kidder, well known as a maker of electric apparatus for medical purposes. He said the idea that such a Rhumkorff coil as that was exceedingly dangerous was an exaggeration, and he was willing to take the strongest shock I could give. I said to him, "If you want to take the risk, I am ready, but bring witnesses." He came with witnesses, and one of them was a reporter of the New York *Tribune*. I gave Mr. Kidder small shocks at first, gradually making them larger and larger and he stood it perfectly well and it did not knock him down. He had great power of resistance. The next day an article was published in the *Tribune*—it was a sensational article—headed, "An Error in Science Exploded," and there it was said that all the talk that electricity could kill was nonsense; that the strongest machine which ever had been made was now at the Cooper Institute; that it was the strongest was proved by the fact that it had cost not less than $400 (laughter), and that Mr. Kidder, the well-known electrician, had stood all the shocks from it, and it gave a great many details which are very amusing to a man posted in electrical science.

Dr. Moses—The proposed experiments on animals would be very interesting, but it would be very difficult to make the conditions sufficient to satisfy all the requirements that are necessary for accurate experimentation. If you consider that the resistance of a man's body may vary under certain circumstances from ten or fifteen thousand ohms down to four or five ohms, it is necessary that the experiment should be conducted in some uniform way. The skin is an excellent insulator, the blood an excellent conductor, the perspiration an excellent conductor. The varying pressure that we apply in coming in contact with a conductor is a cause of immense variation in the amount of current that passes through us. The skin varies in thickness, so that it is necessary in making experiments to take one constant place and one constant thickness. It will be a very difficult thing to try the experiment, but still it would lead to good results.

Mr. Martin here resumed the chair.

Mr. Francis B. Crocker read a paper on "The Possibilities and Limitations of Chemical Generators of Electricity." (See p. 248.)

Mr. Crocker continued as follows:—In regard to primary batteries I do not wish to be regarded as entirely skeptical. As I have said, the possibilities are almost infinite, but there are certain facts which cannot be overcome, which might as well be looked at straight in the face in the beginning rather than after a company is formed to exploit a primary battery and the failure occurs. There are certain legitimate applications of primary batteries even in their present state of imperfection. For example, a primary battery, Leclanché cell, is very satisfactory for ringing electric bells—we do not need a dynamo for that purpose—and for telephone work, and even for small power uses, although I have not yet seen the battery which will practically generate electricity for a reasonable price. As a luxury we can have a battery, or for some very special work like a dentist's or a physician's work, where a horse-power hour may be worth $1,000. There, one could afford to use the silver-chloride battery and throw away the silver.

DISCUSSION.

Dr. Moses—We are very much indebted to Mr. Crocker for the able paper, and we cannot too highly value the time, the energy and self-abnegation devoted to preparing such a paper. There are some questions he will permit me to ask him that will lead to others, and in that way to a useful debate. I notice that in this table D you have used chlorine, bromine and iodine for the three elements that you combine. Why did you select those whose atomic ratios are perhaps less accurately determined, and which are not absolutely considered as elemental in their character? Why did you not, perhaps, take a combination of oxygen or even carbon for that purpose?

Mr. Crocker—In the first place, as I have said, oxygen, pure and simple, cannot be combined directly with zinc. You cannot have free oxygen. It will not dissolve in the solution—to a certain extent it will, and it would be possible to use it, but only in a very delicate way. Whereas, bromine, chlorine and iodine will actually be dissolved in the solution and be used in an elementary state. So far as the elementary character of bromine, chlorine and iodine is concerned I have never heard it assailed before. If you mean that all so-called elements are not elements, and that hydrogen is really the only element, why, then, of course, they go with the others, but so far as I have ever heard they stand on the same basis as carbon, oxygen and so on; and, furthermore, they constitute a series of chemical elements; they are related to each other, and in that way they are successive elements, so to speak. The results obtained are more clear and more instructive when a series of elements is used in that way than when you pick out elements at random. The real depolarizers are those elements, chlorine, for instance, and bromine and iodine. Now, chromic acid itself is not a depolarizer; it is merely the oxygen it contains. In that case you use oxygen, but you do not use it pure and simple; it is a combination with chromic oxide, and therefore the oxygen is complicated.

Dr. Moses—Would you also tell us why you prefer not to determine accurately the amount of water that you used for solution? Do you not find, since water is essential, that its chemical equivalent and its relations to the substances in solution should be just as accurately determined, though we are inclined to consider a solution is not a chemical combination? Still, for these purposes these elements go through combinations through the solution. Therefore, why is it not essential to determine about the water?

Mr. Crocker—The water is merely a medium for the action to take place in; that is really the chemical fact. Of course I could put in the tables in the case of the weights, about how much water an ordinary solution would require, but that really would be mere guess work. The best you could do would be to find when you obtain the maximum results, and that would be a very difficult question; but I find that it makes very little difference in electromotive force whether a strong or a weak solution is used. It makes *some* difference. The stronger the solution the less the electromotive force. The variation may amount to, say, between $\frac{5}{100}$ and $\frac{1}{10}$ of a volt; with the concentrated solution the electromotive force would be that much lower than in a very weak solution. That is because there is so much tendency for the metal to go in solution. The solution is already satisfied; whereas if the solution is weak it has an affinity for the metal. That is the way I explain the fact.

Dr. Vander Weyde—I cannot refrain from paying a compliment to Mr. Crocker (applause) for his very useful labor. It was just the thing that was needed. I wish to make one remark about the function of water in the battery. I would like to hear Mr. Crocker's opinion about a widely adopted theory that the water is the main agent in batteries, that it is the decomposition of the water which does the work, that the oxygen of the water combines with the zinc or other metal that is oxydized, and that hydrogen is developed, and a layer is formed which is the cause of polarization, and in order to get rid of that hydrogen the depolarizers are applied. I would like to hear Mr. Crocker's opinion about that theory.

Mr. Crocker—As regards the function of the water in the battery, it may be called a metaphysical point. (Laughter.) The water may act and give up its oxygen. The hydrogen may give up oxygen on one side and turn around and get some more on the other side. So far as I can see it is water all the time. It is not changed, it acts as a transmitter; that is all it does. It acts as a vehicle. But after the action is over there is just as much water there as there was before, unless it has evaporated; and, in fact, some chemical actions involved in batteries produce water, and in that case there would be more water at the end of the action than there was at the beginning. Then the action would take place exactly the same in the anhydrous state, whenever it is possible to get that state. For example, with a fused salt the action is exactly the same. The zinc would combine with chlorine in fused chloride of zinc, as I have myself proved by experiment, and give substantially the same electromotive force as it does in the presence of water. Water is merely a means of getting a liquid which it is necessary to have as an electrolyte. Electrolytes must be liquids. Now, you can obtain those liquids by fusing your solid electrolyte or by dissolving it. Therefore, I always look upon the water as a medium in which the action takes place.

Dr. Vander Weyde—But the question naturally follows that if the zinc is oxydized by the oxygen, what becomes of the hydrogen at the point of contact with the oxygen? Then there is more than a mere vehicle. We see that the hydrogen is developed at the platinum or silver plate.

Professor E. L. Nichols—I would like to supplement Mr. Crocker's statements by an observation in reference to the behavior of iron, and I presume what is true of iron will be true of other metals which form two salts. If you take iron and platinum in a solution which will produce a ferric salt and let the cell stand so that the iron becomes surrounded with a film of its own salt, then the ferric action will gradually cease and ferrous action will take place. After the cell has stood some time, the electromotive force will rise about one fifth, and you can instantly restore it to the condition it had at first. If you take a porous cell and separate your iron and platinum, put the oxydized solution in connection with platinum, and then around the iron something which will produce the ferrous salt, you will find that that battery has about one-fifth more electromotive force than in the case of the ferric. It seems as though a more successful battery ought to be made with iron producing the ferrous salts. You gain almost enough to make up the difference between iron and zinc; but the behavior of iron is very unsatisfactory, and the reasons for it are not always very clear. It seems as though oftentimes it is due to the formation of oxydizing films which run the resistance of the cells up to an enormous amount. I have known the resistance of bichromate cells to run up to several hundred ohms in the course of an hour or so by the formation,

apparently, of an insoluble film of some form of iron which was almost a non-conductor. Perhaps iron, if worked out patiently, might give us a very cheap metal for a battery and reduce the cost of galvanic electricity very considerably.

Mr. C. O. Mailloux—I would like to ask, in view of the discrepancy observed between the calculated and determined electromotive force, what standard Mr. Crocker used, what value he assigned to it, and upon what authority, so that we may know what kind of a volt he used.

Mr. Crocker—I used constant Daniell cells, but independent ones set up separately, and with chemically pure sulphate of zinc and sulphate of copper, solutions half saturated. Then I further checked the results by two electromotive forces which I happened to know and had previously determined very many times, and those are the bromide combinations of zinc and iodide. That in itself is an excellent standard cell—free bromine and zinc. It gives an electromotive force of 1.79 volts. That is the result, I suppose, of a thousand experiments. Therefore in going through my experiments when I came to the combination zinc-bromide and found that it gave an electromotive force of 1.79 volts, I felt perfectly at home, because I had been there so often before; it corroborated my standard. Then the combination of zinc and chlorine, 2.11 volts was also very frequently determined, and of the Upward battery which came out about a year and a-half ago in England, the published electromotive force was 2.11 volts. So there were several corroborative facts. So far as my experience goes, a standard Daniell cell does not vary very much in electromotive force.

Professor Thomson—I would like to say just one word on this subject. It has probably been a common experience of those having Daniell cells in operation to notice, if the solution is not kept up to a high degree of strength, that oftentimes the upper part of the copper will be eaten out, and the electrolytic deposit of the copper made in the lower part of the cell where the solution is strong; or, in other words, there is an indication of a difference in the volts which carries on a sort of plating action on the copper plate itself. Whether this be due partly to the effect of the acid, or that the solution comes through from the porous cup and floats on top causing a difference in the electrolytic condition of the fluids alone, setting up current, I do not know. But it recalls to my mind an observation several years ago on the effect of simple heating of the solution. Putting at the lower part of the test tube a little spiral of copper wire and carrying out a connection by an insulated covering from that spiral, filling up the test tube partly with sulphate of copper solution; putting another little spiral near the top of the fluid and then heating we find a difference of voltage, and it amounts, I think, to something over one-twentieth of a volt, if I remember the results of the experiments correctly; showing also that a solution of the copper—if we short-circuit such a battery—will be expected to take place and a deposition of the copper in the cold liquid. In other words, the hot liquid is more of a solvent than the cold, although it is a sulphate of copper solution. Whether Mr. Crocker has taken into account the temperatures of the solutions in making these tests I do not know.

Mr. Crocker—I made the tests at the normal temperature. It did not vary five degrees from 68 F.

Professor Thomson—It is probably well understood nowadays that not all the elements are to be considered as real elements as we find them. I do not mean that they are decomposable into hydrogen, although I think that quite possible, and perhaps even to a far more primitive condition than hydrogen if we could use forces which we have not at hand—I mean the celestial forces. I mean that each particle of copper known to us is a combination of copper with copper; that the atoms really form a molecule which is a real compound. Two atoms or more atoms may be found united, but it will certainly take something to decompose those molecules even though they be combinations of the same atoms. I am struck with the results obtained with aluminum in the work of Mr. Crocker. We find actually that this metal so hard to get at is really capable of giving an electromotive force less than zinc; so that it would seem as though by the proper use of zinc in some way or other we might separate aluminum. In other words, its electromotive energy is very much less than zinc, and in some cases not very much different from iron. In the recently developed reduction of aluminum we find that carbon at high temperature reduces it with comparative facility, and it may be that after all, all we have to find is something which will fluidize or liquify the aluminum, and we would then find that even common materials like zinc or iron would separate these combinations.

Mr. Crocker—In regard to that aluminum question the same thing struck me that Professor Thomson points out. By my experiments aluminum is apparently less electro-positive than zinc. I do not think that is actually the fact. I think there is some loss which occurs—loss of electromotive force. In fact the calculated results are higher than those of zinc, and it might be that aluminum forms an insoluble compound on the plate.

Dr. Vander Weyde—It may be useful to state here that twenty years ago I attempted to substitute aluminum for platinum in the Grove battery. The result was negative. I scarcely got any current at all. It appeared that aluminum had not the power to decompose the nitric acid and produce the nitrous acid fumes customary when we use platinum in the Grove battery.

The Chairman—The next paper on our programme is that on "Compensated Resistance Standards," by Professor Nichols, of Cornell University.

It affords me the greatest pleasure to announce that our president, Mr. Edward Weston, who has been quite ill, has sufficiently recovered to be with us, and is now here, and that he will preside immediately after lunch.

Introducing his paper, Professor Nichols said: "I would like to state that the experiments I am about to describe had their origin simply in the desire to find something that could be used for a low resistance shunt or for a low resistance standard, and which would obviate the difficulty which every electrician meets with in electrical measurements on account of the influence of temperature upon conductivity. I suppose there is no correction which we are obliged to make which is so troublesome as this one of the temperature coefficient. If it were merely a question of change of the temperature of the laboratory, we could correct for that. We could determine our coefficient and make the proper correction; but whenever current flows it heats the wire to a temperature higher than that of the room, and in the case of heavy currents this difference of temperature will be a large one, and one which cannot by any ordinary means be accurately determined; and so there is always an element of uncertainty in the use of a coil through which a current flows, and this has proved so serious, as doubtless many of you know, as to lead to the discarding, for accurate work, of shunt methods of measuring heavy currents." (For Professor Nichols's paper see p. 246.)

DISCUSSION.

Mr. Wheeler—I would like to ask Professor Nichols if he has any explanation of the sudden drop at about 22 degrees centigrade. I would also like to say that Professor Thomson called my attention to the fact that he had made a bar by leaving the varnish complete all the way around, and then putting lampblack on, or graphite, and plating a complete copper tube upon it, and then connecting that at one end so that you could send the current through the length of the carbon.

Mr. Nichols—The only trouble is that the amount of copper required is so small that it is difficult to get a small enough amount. You must have 11 ohms of copper and that means a very small tube. The very slight change, in my opinion, is not due to incomplete compensation, but to accidental causes. It is very difficult to get rid entirely of thermo currents. It is perfectly thinkable that there might be some irregularity in the temperature coefficient which would make the compensation slightly incomplete. At intermediate temperatures I do not think it is noticeable.

At 1 o'clock P. M., a recess for lunch was taken.

AFTERNOON SESSION.

The Chairman—At the opening of our morning session I had to announce that through serious sickness our president, Mr. Edward Weston, who was unanimously electedl ast evening, was unable to be present. Mr. Weston has, however, made a great effort to be with us to-day and comes here from a sick bed. I think in securing the services of Mr. Weston in the presidency, the Institute has secured one whose international reputation will be of benefit to it through the coming year. The Institute, as you are well aware, is a society whose membership is not confined merely to New York, but extends throughout every state and territory of the United States, and includes to-day almost every civilized country. Mr. Weston's reputation as an electrical engineer is co-extensive with the membership of the Institute, and I am therefore very glad to salute him as my successor and now to present him to you.

Mr. Weston took the chair, and addressed the meeting as follows:

Members of the Institute and gentlemen: I am not quite so sick as our retiring president, Mr. Martin, would lead you to believe; but since yesterday I have made a few trips between the Equator and North Pole. I have been jumping from pretty wide extremes you see. To stop the too rapid motion I have taken considerable quinine, and it leaves me in a somewhat befogged condition of mind. I am, therefore, not feeling well enough to address the Institute in the way that I should do in accepting the presidency. I feel extremely honored by the kindness of your selection. I accept the office with grave doubts, because I question whether I can give so much time to it as our past worthy president has done, or can achieve in the same time so remarkable a growth for the Institute. I am informed that in the year of his presidency the membership of the Institute has about doubled—an indication of excellent work. The papers that I have read—and what I have seen of the proceedings—have been worthy of the society. The character of the papers shows a constant upward tendency. I hope it will continue so. We have nothing to be ashamed of in the past, and I hope we shall find nothing to be ashamed of in the future. I had intended to speak in full of the present state and future progress of electricity. I am unable to do that to-day. I really cannot undertake it. Therefore, I beg to

apologize for disappointing you. I am not in fit condition even to occupy the president's chair, and as Mr. Martin has suggested that he would rather withdraw to-day, I would like Mr. Upton, if he would kindly do so, to accept the position this afternoon. (Applause.)

Mr. F. R. Upton, vice-president, took the chair.

The Chairman—The first paper read was on "A New System of Alternate Current Motors and Transformers," by Mr. N. Tesla

Mr. Phelps—I would like about two minutes before the paper is read. I do not rise to propose a vote of thanks to our retiring president, because I think votes of thanks, like the resolutions in political conventions, "pointing with pride," etc., have become a custom more honored in the breach than in the observance. But I do feel that a word ought to be said—and I feel very confident that I express the general opinion—recognizing the zeal, the activity and the intelligence which has characterized the administration of the office of president during the past year. The growth in membership, the character of the work accomplished, and in general all the activities of the Institute during the past year, constitute a record to which I think we shall always look back with satisfaction and with reasonable and just pride. It has been a matter of astonishment to me to observe the amount of time and the intelligent effort which so busy a man as our ex-president has found it possible to give to the interests of this Institute. He has not spared himself in any particular; there is no work that he could do that has been left undone, and our condition at the present time is a sufficient evidence of the truth of what I say, and I have not the slightest doubt that all here present join me and feel that I make no more than a meagre statement of the facts. (Applause.)

The Chairman—Is any formal motion to be made and entered in the minutes?

Mr. Phelps—I think not, sir. As I expressly stated, I would prefer, as far as I am concerned, to avoid a formal motion. But the way in which my remarks were received sufficiently justified my belief that they expressed the general sentiment of the members present.

A Member—I would move that the remarks made by Mr. Phelps be heartily accepted, approved and endorsed by the society.

The motion was seconded by Mr. Wheeler.

Capt. Michaelis—I would merely like to add one word to the enconium pronounced by Mr. Phelps. I have been fortunate enough to be associated with our past president in the council during the past year, and I can heartily endorse everything Mr. Phelps has said. I would like, however, to call the attention of the Institute to one point in which they are indebted to our past president alone, and that is the valuable addition to our transactions in the shape of the bibliography that now appears with them regularly. That was Mr. Martin's idea, and it has been carried out by him. You all must know how much time such a thing has taken, and he has done that entirely of his own motion and for the good of the Institute. (Applause.)

The Chairman—I understand the motion to be that the remarks of Mr. Phelps be added in full in our minutes, and with the cordial approval of the members. All those approving will signify by rising.

The motion was unanimously carried.

Mr. Tesla, before reading his paper, said: I desire to express my thanks to Professor Anthony for the help he has given me in this matter. I would also like to express my thanks to Mr. Pope and Mr. Martin for their aid. The notice was rather short, and I have not been able to treat the subject so extensively as I could have desired, my health not being in the best condition at present. I ask your kind indulgence, and I shall be very much gratified if the little I have done meets your approval. (For Mr. Tesla's paper see p. 252.)

DISCUSSION.

Mr. Martin—Professor Anthony, I believe, is here, and as he has given this subject some attention, I think he might very properly supplement Mr. Tesla's paper by some remarks.

Mr. Tesla—I want to express once more my best thanks to Professor Anthony for aiding me in many respects, and I hope he will be able to explain many of the features in this system that I was unable to explain at present.

Professor Anthony—Mr. President and Gentlemen: I have been referred to as having had something to do with these forms of motors. I am very glad to be able to add my testimony to what Mr. Tesla has already given you in regard to their action, and I confess that on first seeing the motors the action seemed to me an exceedingly remarkable one. After my first visit to Mr. Tesla's works, some of the motors, I think these very two that you see here on the table, were brought to me to make some tests of their efficiency, and probably you will be more interested in those than in anything else that I might say. I am sorry I have not brought with me the exact figures that we obtained, but I can give you from memory something of the result. This little motor that you see here gave us about half a horse-power, and gave an efficiency of something above fifty per cent., which I considered a very fair efficiency for a motor of this size, as we cannot expect on such small motors to get as high efficiency as we can on larger ones. This, I believe, is the armature that Mr. Tesla calls the armature for high rotary effort. This little pulley, which is only about three inches in diameter, gave a pull of something like fifty pounds, as I remember it on turning on the current, so that you see the rotary effort is very considerable, and that is also shown in the quickness with which the armature will reverse its motion on reversing the relation of the two currents which pass through the two opposite coils. That could be done by shifting two of the wires, or simply shifting a reversing key in one of the circuits, and the armature would stop and reverse its motion so quickly that it was almost impossible to tell when the change took place. That shows also the very considerable rotary effort that the armature presents. This motor (referring to the second specimen) gave us, I think, about 1¼ h.p., and showed a somewhat higher efficiency than the other—a little over sixty per cent. This would run, with the armature as here constructed, almost at the speed of the generator even under a very heavy load. When the load was brought up to the maximum load, where the efficiency began to fall off somewhat, the speed of rotation was reduced. As I remember now, it was reduced to about twenty-eight hundred, and the speed, you see, kept up very nearly to that of the generator under heavy load.

I can add very little to what Mr. Tesla has already given you in regard to these motors. I have no question but that all of you would be as much interested as I was in seeing them work. That is really the best way in which to determine what the motors will do.

Mr. Tesla—Mr. President and Gentlemen: Professor Anthony just made the remark that the speed of this motor fell off when the load was increased. That was due to the fact that this armature was designed to secure a strong effort from the start. But if we make an armature which is only designed for synchronism, the speed will always be the same no matter what the load; only there is a disadvantage that at the start the rotary force is so small that it is apt not to start. It would generally start if put in a proper position, but if not put in a proper position it might not start. If we employ an armature consisting of a cut-away block of steel with a coil, it will maintain its speed at all loads. The importance of maintaining the intensity of the pole constant is that if this can be produced we can utilize, instead of the subdivided armature, an ordinary steel block with the same result. It is only desired to close the magnetic field. You can readily see, if the poles are fixed, that it is not necessary to subdivide the armature, if the intensity of the force is constantly maintained the same. But, if the intensity is not maintained the same, then it is necessary to subdivide, and generally in the results that I have obtained I have found that it is necessary to subdivide. I have also observed that in the tests of Professor Anthony the results obtained were superior. I attribute that to the fact that the dynamo has got a powerful field and a small armature and the field is very concentrated, and for that reason probably, the result is nearer a theoretical result.

Professor Thomson—I have been very much interested in the description given by Mr. Tesla of his new and admirable little motor. I have, as probably you may be aware, worked in somewhat similar directions, and towards the attainment of similar ends. The trials which I have made have been by the use of a single alternating current circuit—not a double alternating circuit—a single circuit supplying a motor constructed to utilize the alternation and produce rotation. I have carried on since the last annual meeting of the Institute the development and perfecting, as far as my time allowed, of a closed circuited armature—if we may so term it—related to the alternating field. That is, the plan which I used and which I brought to the notice of the Institute last year, was to make a laminated field and in that field to place an armature also laminated, winding upon the armature a coil which periodically is close circuited during the revolution by a suitable commutator or circuit-closing device. I have made several such motors on different designs and they uniformly start from a state of rest and develop power, and some of them show, at speeds close to the rate of alternations of the dynamo, a tendency to synchronize. Their rotary efforts in most cases is a little greater nearer that point than at other points. I hope sometime before a great while to bring most of these results before the notice of the Institute, and I would therefore prefer delaying further remarks on motors of this description. I certainly think there is a field for alternating motors, and there is undoubtedly an opportunity for obtaining motors which possess even some advantages over the continuous current motors.

Mr. Tesla—Gentlemen, I wish to say that the testimony of such a man as Professor Thomson, as being foremost in his profession, flatters me very much. I might say that I have worked in the same line with Professor Thomson at a period when the invention of Professor Thomson was not known to me. I had a motor identically the same as that of Professor Thomson but I was anticipated by him. I believe that although that peculiar form of motor represents the disadvantage that a pair of brushes must be employed to short circuit the armature coil, that such a form of motor may be made practicable for the simple reason that a motor represents a transformer, and such a transformer we well know we can bring to a very high efficiency. On the other

hand, the armature may be provided with conductors that are of comparatively low resistance, and it is a mere matter of making a perfect arrangement for short circuiting. You will see the advantage of this disposition of the closed circuit coil—that this action is always maintained at the maximum and it is indeed more perfect than if the polarities were shifted by means of a commutator.

The Chairman—Unless there are some other remarks on this subject we shall have to pass to the consideration of the next paper. I think thanks are due to Mr. Tesla for his paper. The next paper in order is "Underground Electrical Systems in Europe and America," by Professor G. W. Plympton, of the Brooklyn Subway Board.

Professor Plympton—Mr. President and Gentlemen of the Society: This is a place in which I should seek to stand for instruction rather than to impart any information. I have looked for a long time to gentlemen of this organization for information to guide me in the work I am doing. I shall be very brief with the so-called paper, and will give a little of what I have to communicate orally in the way of a description of some plates and a narrative of my journey.

After reading his paper (see p. 260), Professor Plympton said:

The impression that I had received from conversations with people who had seemed to know, was that a large part of the telephone service of Europe was buried in the streets. I was partly disabused of that idea by an engineer who had returned from Europe just as I was setting out. I went to London. I was furnished with letters to various engineers, by engineers and managers of telephone and telegraph companies and civil engineers. I first made the acquaintance of Mr. W. H. Preece in London, and learned from him that the postal telegraph wires were buried in the street, and that some telephone wires were buried with them—enough for the service of the post-office department. A telephone company enjoying franchises in London have run all of their wires overhead, as the manager informed me he could not put a wire underground without an act of Parliament. They bought their right of way over the house-tops. There are certainly wires enough in many places there. They do not compare in number and entanglement with ours in New York, simply because there is no such telephone service there as we are familiar with here, nor is there in any other place. I had submitted the question as to the material of the conduits. He said that after going through a good deal of experience they had adopted iron pipes for their conduits and drew their cables loosely through them. Wires were protected singly, and then two or three or ten or a dozen wires were twisted together and pulled through the iron pipe—generally a three-inch pipe, rarely larger than four inch. If it was necessary to make connection at some point not contemplated before the pipe was put down, they simply knocked a hole in the side of the pipe with a hammer and made the connection. When inquiry was made what they would do in case of so many subscribers along any line of telephone conduit, such as we have here in New York, they said that problem was not yet presented to them in London. I went on there to make another visit afterward. I simply examined the system in the streets. These pipes were buried about sixteen or eighteen inches, rarely as much as two feet, ending in little cast iron boxes about twenty inches by sixteen and perhaps a foot deep, fitted with an iron cover tightly cemented. They sent workmen out, and I was accompanied by Mr. Fleetwood to examine the boxes. They had difficulty in raising one or two. I asked why they were so tightly cemented. They said to keep water out. I asked if that was really the effect. They said they thought it was, but the first cover they took off showed me a box with about two inches of water in the bottom. In submitting the question of material of a conduit to Mr. Preece, he answered that iron was used because it would serve better to protect their wires from injury when the streets were dug up by workmen; pick-axes would knock everything else to pieces. He spoke well of our plan of creosoted timber, and took from a case in his office a piece of an old conduit put down in 1853. It had been in the ground thirty-one years. It came out perfectly sound. The cable had given out years ago. It is known that they began systems of telegraphy in Europe by burying all their wires. They tried to bury them along their lines of railway; afterwards dug them up, and now their wires across country are on poles. They are burying in some places in the cities.

Brussels I visited next, and there found a system of arc lighting. Wires were stretched along the street. None were buried. Telephone wires are over the housetops, the wire being in some cases a hard drawn copper wire, in others a silicon bronze. As the houses are high and the house attachments are high, these wires run pretty well up in the air, and as they are small they do not attract attention as they do here. That is the case generally throughout Europe. They use a small wire, and the housetop fixtures are so high that they are not apt to attract attention. A gentleman on the steamer gravely told me that he had been all over Europe and did not see any wires in the air at all; he knew they were all underground. As the chief manager of the telephone system was in Antwerp, I went on to Antwerp to get such information about such telephone service as was under his control. That was Mr. DeGroof. He very kindly offered his time to answer as many questions as I chose to ask. I thought of going on to Stockholm, for the reason that I understood the service was very good there, but I learned from Mr. DeGroof that everything was put up under his direction, and, with the exception of the framework on the housetops, everything in Stockholm was exactly duplicated in Antwerp. He thought that no telephone wires in Europe were underground except those that there were in the sewers in Paris. He proved to be not quite correct, though pretty nearly so. I asked about his housetop connections. He said all through the Belgian and Scandinavian cities they were on housetop fixtures. In Italy they were on brackets under the eaves, for the reason that the tiling of the roof does not support very kindly these immense wooden structures. To preserve some degree of coolness in their roofs they put on a triple tiling with little air spaces between the tiles, and it almost destroys the whole roof to put up a wooden structure. Hence they attach it by brackets under the eaves. The style of these you will have an opportunity to see, as I have had these systems extensively photographed in many places in Europe. Mr. DeGroof added that one company had come there with an electric lighting system—he told me the name—and had buried a cable for a short distance, with the intention of lighting the street. It was all buried and they were nearly ready to start, when the gas companies came forward and proved that they alone had the right to dig up the street—the right of canalization of the streets, as he expressed it. The whole plant was lost and lies buried in the street. He mentioned as an interesting fact that he tried a new plan along the shore of the Scheldt. He had just put up a mile of poles to support his wire. That was a pole line in Europe that they felt rather proud of. I had it photographed and received the photograph since. In Berlin the circumstances are not widely different. There is a series of lines under the municipal direction and some under the direction of the government. There has been a little friction between the two. The first official that I consulted assured me that all telephone wires were on the housetops; nearly all telegraph wires were buried in the street and at no great depth, very much like the wires in London, in pipes, not far below the surface. The German military telegraph is of another kind. That is the Siemens cable strongly wound with an armor and buried without any other protection directly in the ground. The telephone wires are very abundant in Berlin over the housetops. There is quite a tangle of them, as you will see by many photographs here. I should add that in Brussels perhaps the most remarkable display of wires anywhere is shown by that photograph. (Showing a photograph.) It is a fine picture of their chief cathedral, with wires spread above and running a long distance to their support. In Berlin the housetop fixtures are really very extensive. I never have seen any in New York which were able to carry as many wires at once as those of Berlin. As the government controls the placing of the wires, they are frequently placed on their best buildings, and some of the very fine views across their favorite avenues show these light iron fixtures on top of public buildings. The difference between the German service and that of Belgium is that in Germany the householder must submit to having the fixtures put on his house. He is paid, however, for the service. In Belgium they make the best terms they can, and the telephone companies pay at about the rate of ten cents per wire per year for the use of the housetop.

One picture represents Turin, where there is a great assemblage of wires coming over the housetops. In Brussels one difficulty which Mr. DeGroof said he had experienced was from the disturbance of the wires by angry citizens. The wires were so thick that they killed a great many carrier pigeons. Owners of pigeons would get angry and go up on the housetops and cut the wires. Fifty wires were interruped the day before. An old lady who owned a number of pigeons had cut them down. Cologne has, I think, about fifty—it was August, 1886, that I was there—and Frankfort about four hundred. Four, five or six hundred is about the number for those cities in central Europe.

In Paris a different condition prevailed. I went directly to the electrician. I had letters from Mr. Edison and Mr. Vail introducing me to M. Berthon, in whose charge are all the telephone lines of France. I asked him immediately about his underground system in the sewers. He said, "Yes, they are in the sewers, but they are there because the sewers are right at hand." I asked him "What do you do when you come to the end of your sewers?" He said, "Then we come out and go to the housetops." A little later he showed me a wire drawn out of a sewer—drawn right up, fastened to the side and drawn up to the house where it is wanted. I asked him what was the plan in other French cities. He said they were all on the housetops except in Bordeaux, where about three hundred subscribers are furnished by a system drawn through iron pipes, but they were not doing very well. Then I asked about the electric arc lights. I visited the sewers and walked along through them some distance. I noticed the method of attaching. It was a little hook with a shank, driven into the wall overhead; I could just reach them with my hand. That would hold four or five cables as large as my thumb. There would be twelve or fourteen of those small cables in a single one of these sewers. It was easy to make out the distance of these cables as they branched off, because the sewers are very conveniently marked—the street corners are marked with the name of the streets. In regard to

the arc lighting I asked him if he would put the arc light wires in the same sewers with his telephone wires and he said, "No," very energetically—he would not have them there; indeed he did not believe that arc lighting was going to prevail to any great extent, and then added, "We have less now in this avenue that you are in than we had three or four years ago; we have replaced the arc lights with the gas lights." The gas lights are in groups, five or six burners in each lamp. There were no arc light wires underground, so far as he knew. I noticed while walking with him along the street that there were some wires overhead. He said those were some of the dead wires not yet removed; but he called the superintendent who was in sight, and submitted the question to him. The superintendent said no, that the wires were overhead as there was no sewer in the street: it was a little street. Then M. Berthon added, "There are one hundred subscribers served that way," and again the superintendent interposed to say that there were two hundred in Paris served over housetops solely. He added that in regard to the service that he expected to be able to extend through Spanish cities, it was a franchise that he was expecting to control very soon, but he had made it a condition that he should be allowed to go on housetops. So I got but little information with regard to the best way of burying wires until I got back to England, when, after a short stay and another consultation with the electricians there, I went on to Newcastle. I was assured that they were beginning to put wires underground in Manchester If I went there I should see that they were burying a cable in an iron pipe. Newcastle enjoys the reputation of having all its wires underground. They have a system of iron pipes. They serve some three hundred or four hundred telephone subscribers by the use of the wires. They are controlled by the government. They do not study economy in the method of hauling in wires or in the use of them. They twist their wires together so as to establish a metallic circuit and run from their central station to their customers. I had got this estimate both from M. Berthon and Mr. Preece that when the underground system was fully at work with cables the best that they knew how to make, the limit of service would be about ten or eleven miles underground. I asked if it would be profitable to run further than that if you come out of the ground at that distance. They said that was doubtful; it was a question not solved. M. Berthon stated about twelve miles as the limit at which it was possible to send a telephone message through anything buried in the ground. I mentioned that to the electrician who was assigned to me by Mr. Heaviside, the head of the telephone service in Newcastle, and he said: "I cannot quite accept that estimate, and I think I will give you an opportunity to refute it." So he connected up a line for me to experiment with which he said was a line of twelve and a half miles of cable—what he called cable, that is a lot of wires twisted together in pairs, twisted a little way in one direction and then twisted in the opposite direction. These pairs were put together until there would be about a dozen or twenty, and then they were pulled loosely through the iron pipe. At the end of the twelve and a half miles the wire came out of the ground and connected for about 38 miles further. It was 50 miles and a fraction through which, he said, the telephone service extended. I could converse through that, though I found difficulty where an expert worker at the telephone would not. I could converse through that when the conditions were exceptionally favorable. It was in a padded room and the instrument was in perfect working condition. I had no difficulty in conversing through that twelve and a half miles of cable and the aerial line up to fifty miles. Such telephone service as they have in Newcastle would hardly answer the purpose where there are so many users as we have here. I asked how they increased the number if they had any additional subscribers—how could they pull more wires into the iron pipe that had a twisted tangle of wires already in it. He said they pulled the whole bundle out and sent them to headquarters—the postal department—and they furnished them a new lot. Economy was not considered. He said the government owned the whole thing.

Mr. J. A. Powers—As an operator of a central station lighting plant, I would like to ask what is the longest time—if there are any arc light wires buried underground—what is the longest time during which such wires have been buried up to the present time.

Professor Plympton—I cannot tell that. We have had no experience of that kind in Brooklyn. The arc light company appears to be ready to try experiments when they see their way clearly. We have been more interested in getting the telephone wires underground because they out-number all the others.

Mr. Powers—There seems to be in this matter a very grave misunderstanding by the public as to the danger of the electric light wires themselves. I have kept close watch of this matter since there has been some agitation of the underground question at Troy. I have kept close track of the accidents recently, and I have noticed that four out of five do not occur from the electric light wires directly, but from the coming down on the electric light wire of abandoned wires overhead. The nuisance has become so great in Troy that an ordinance was recently passed by the common council requiring the city engineer to remove those wires, and there is now a mutual action of the telephone, telegraph and electric light companies to see to the removal of "dead" wires. We had one accident a short time since. An abandoned Atlantic and Pacific telegraph wire fell down across us and killed a horse, through no prime fault of the electric light company. If we can get the telegraph and telephone wires underground, which seems to be possible, we shall have, if the recent accidents are any criterion by which to judge, four-fifths of the danger removed at once, and I think that the question of danger will then sink into comparative insignificance.

Mr. Mailloux—I would like to ask Professor Plympton if he can tell us about the working of the underground system at Chicago? I believe the underground system has been working there on a considerable scale.

Professor Plympton—I visited Chicago, and was very politely received by Mr. Barrett, who is superintendent of the work there. He said that he began by forming an agreement with various companies that they should bury their wires as fast as he buried the wires of the city. He is city electrician. He allowed the companies to select their own conduits, so that each company has its own. They have telephone wires, telegraph wires, underground electric light wires for some purposes. There is no municipal street lighting in Chicago, or was not a year ago last February. Some theatres and buildings are lighted, but they run through conduits. That was the case where one of these took fire. I wrote to Mr. Fay and asked about the telephone service, to learn if they had suffered from induction from proximity to any of these other wires. They had in some cases. The harmonic system of telegraphy had created some difficulty through its induction, and there had been complaints, but inasmuch as each company had selected its own conduit and buried its wires in its own way, there was not much to gather about a general system of burying, of getting them into as compact shape as could be done. Indeed, standing at one of the street corners one of the electricians pointed out to me fifteen man-hole covers in sight at the junction of two streets, all within a radius of less than sixty feet. They have there a short way of making connection. Their soil is soft, light sand. They take a sharp pointed pipe and drive that pipe right across the street if they want to make a house connection. It may turn out in the middle of the track and then they pull the pipe out and start again.

In regard to getting information from other sources, the remark made by Mr. Parish in London was significant. He said, "If I had been asked about the best place to go to to learn about underground systems I should have said the United States. We haven't got any here." I found that to be the case. They can come here to learn about underground systems. They cannot overtake our rapid development.

The next paper read was on "The Patent Court and Uniformity in Patent Practice," by Mr. George H. Stockbridge. (See p. 257.)

Mr. Stockbridge preceded his reading by saying: You will remember that some time ago Mr. Steuart, representing the National Electric Light Association, read a paper before you in which he pointed out certain reforms that were regarded as necessary by that association, and there was, I believe, a discussion here of the reforms that were pointed out at that time. I believe it was the design of the association to present bills to Congress embodying the reforms suggested by Mr. Steuart, and embodying them in a revision of the patent law. That scheme, however, met with opposition from some, and instead of that, two bills were presented by the association to Congress, and one of them provides that a patent court be established to have appellate jurisdiction from the Commissioner of Patents in all rejected cases, and the other is that the Commissioner of Patents receive a salary of $8,000. Mr. Steuart asked me to prepare an argument to be submitted to the judiciary committee before whom the bill on the patent court now is, and I prepared such an argument, taking rather a narrow point of view, so as not to interfere with the arguments that were to be made by the other parties.

Professor Nichols then read a paper on "The Swinging Arm Galvanometer." (See p. 259.)

The chairman read the communication from the secretary of the Electric Club, which had been presented at the annual meeting on the previous day, inviting members of the Institute to visit the club house.

The next meeting of the Institute will take place on June 19th, when Mr. F. J. Sprague will read a paper on "The Engineering Problems of Electric Railway Work."

Adjourned.

THE EDISON ELECTRIC LIGHTING COMPANY DEFEATED IN A PATENT SUIT.

United States Circuit Court.—Southern District of New York.

THE EDISON ELECTRIC LIGHT CO. *vs.* UNITED STATES ELECTRIC LIGHTING CO.

OPINION OF JUDGE WALLACE SUSTAINING DEFENDANT'S PLEA.

WALLACE, *J.:*

The plea to the bill of complaint, which has been set down for argument, alleges in substance that the defendant should not be compelled to answer, because by reason of the facts averred in the

plea the remedy of the complainant is plain, adequate and complete at law, and this court should not take cognizance in equity of the suit.

The bill alleges the infringement by the defendant of letters patent of the United States, No. 263,140, dated August 22, 1882, granted to the complainant upon the application of Edison for an improvement in dynamo-electric machines, the invention of Edison. The bill shows that Edison made his application for a patent August 9, 1880, and assigned his title to the complainant June 21, 1881. Besides the averments usually contained in bills to restrain infringement of patents, allegations are introduced by way of anticipation of the supposed defense to the bill in order to meet any issue tendered by the defendants. These averments are in substance that the defendant may wrongfully pretend as an excuse for its wrongful acts in the premises that the complainant's letters patent are no longer in force or operative, because at the time they were granted, the invention described therein had been first patented in the Austro-Hungarian empire for the term of one year, and that such foreign patent has expired, and consequently that the term of complainant's patent has expired; but that the facts are that Edison at the time of making the invention was and always since has been a resident and citizen of the United States, and made, perfected and reduced the invention to practice in the United States, and made and filed his application for a patent in the United States Patent Office, August 9, 1880, and prior to any application made by him abroad, and that in order to protect his invention in foreign countries it was necessary that he should promptly apply for letters patent abroad, and the issue of the foreign patent preceded the United States patent solely because of the greater diligence and more prompt procedure of the foreign administration. The bill further avers that the letters patent of the Austro-Hungarian empire were granted for the term of 15 years from their date, and are in full force and effect.

The plea alleges that prior to the granting of the complainant's letters patent the invention or discovery described and claimed therein had been patented by Edison, or with his knowledge, consent and procurement, by a public patent of the Austro-Hungarian empire, granted to Edison July 21, 1881; that the term for which the foreign patent was granted was one year from its date, and expired on the 21st day of July, 1882; that subsequently, by grant made on the 19th day of July, 1882, the foreign patent was extended for a new term of one year, and the extended term expired on the 21st day of July, 1883; and that the extended Austro-Hungarian patent was existing and unexpired when the complainant's letters patent were granted, but the term thereof expired July 21, 1883, and before the commencement of this suit. The plea denies the averments of the bill that the Austro-Hungarian patent was granted for the term of 15 years, and was in full force and effect when this suit was brought.

If the complainant's patent had expired before the bringing of this suit, it is plain that a court of equity has no jurisdiction of the cause of action for infringement, and the complainant can only proceed by a suit at law for the recovery of damages (Root *vs.* Railway Co., 105 U. S., 189).

It is contended for the complainant that such a defense cannot be raised by a plea, and if it could, that the present plea is insufficient both in matters of form and substance to present such a defense.

One of the uses of a plea in suits at law or in chancery is to object to the jurisdiction of the court (Livingston *vs.* Story, 11 Pet., 351; Wickliffe *vs.* Owing, 17 Howd., 47, 51). In a case where it was urged that the sum involved was not of sufficient amount to authorize a court of chancery to take cognizance of the cause, Chancellor Walworth said: "If that fact did not appear upon the face of the bill, it might undoubtedly have been pleaded in bar of relief." (Smets *vs.* Williams, 4 Paige, 364.)

In Beames on Pleas, 55, it is stated: "Those pleas which are commonly called pleas to jurisdiction do not proceed the length of disputing the right of a plaintiff in the subject of the suit, or allege any disability on the part of the plaintiff to prosecute the suit, but simply assert that a court of chancery is not the proper court to take cognizance of those rights." The present plea falls within this definition.

There is no force in the objection that the plea is a negative plea. Such pleas are sanctioned and are now frequently resorted to. A familiar instance is a plea denying partnership, where the bill prays an account of partnership transactions.

The present plea is not strictly a negative plea. It is a negative plea so far as it denies the averments of the bill that the term of the Austro-Hungarian patent is for 15 years and that the patent was in full force when the suit was brought. It is an affirmative plea as to all the other facts which it sets forth. The effect of the plea is to admit all the facts alleged in the bill except those specifically denied, and to meet the case made by the bill by alleging the new facts intended to show that the complainant's patent had expired at the time of the commencement of the suit. If the bill did not contain the anticipatory averments which have been inserted in it the denial in the plea would have been unnecessary. With this denial in the plea it is only necessary to inquire whether the facts set up affirmatively are a defense to the suit, admitting that everything in the bill not denied is true.

A pleading is sufficient which sets forth documents according to their tenor or legal effect, and avers the substantive facts relied on as a cause of action or defense. Tested by this rule, the plea is sufficient in form without making a profert of the Austro-Hungarian patent, or setting out in detail any of the evidential facts to show that it was a valid grant of letters patent for the invention for the term of one year. If issue were taken on the plea, it would only be necessary for the defendant to produce a properly authenticated copy of the foreign patent and show the seal or signature affixed to it to be the act of an officer duly authorized to issue patents. The effect and operation of the patent is to be determined as a question of law by the terms of the document, unless evidence of the foreign law is introduced to qualify or controvert the construction which would otherwise be placed upon the instrument. It is not necessary in a pleading to allege that an instrument was executed by an agent and that the agent was duly authorized thereto; it is sufficient to allege its execution by the principal. (Delafield *vs.* Kinney, 24 Wend., 345.) The tribunals of every nation take judicial notice of the public seals of sovereign states (1 Greenleaf Ev., Sec. 4); and the annexation of the seal will be presumed to have been made by a person having custody thereof and competent to do the act (Phillips Ev., 419).

The plea sets forth a sufficient defense if the term of a United States patent ends at the same time the term of a foreign patent granted for the same invention ends. when it appears that the foreign patent was not applied for until after the domestic patent was applied for; that it was not applied for by the inventor himself, but by some other person by his procurement, and that the domestic patent was granted to one who at the time of the application was an American citizen and had made and reduced his invention to practice in this country. The question presented depends upon the meaning and effect of section 4,887 United States Revised Statutes, which is as follows:

"No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than 17 years."

It is not at all material whether the foreign patent is granted to the inventor who makes the application in this country or to some other person to whom he has caused the invention to be patented; the statute expressly covers both cases. Nor is the fact of any importance that the inventor who makes the application in this country is one of our own citizens; because since the act of July 4, 1836, which repealed all former patent laws and established a comprehensive code covering the whole subject, our laws have not made any distinction between our own citizens and foreigners in respect to the privilege of obtaining patents or the conditions and restrictions of the privilege granted, except as to the amount of the fee to be paid and the protection of inventions by caveat. The question may, therefore, be simplified by eliminating these immaterial ingredients; and the real inquiry is, whether the section limits the term of a domestic patent to the term of a foreign patent when the application for the foreign patent is not made until subsequent to the application in this country, but the foreign patent issues before the domestic patent.

If it were proper to treat this question as an original one, it would be necessary first to inquire whether there is any ambiguity in the language of the statute. If there is not, the duty of the court is to give effect to its obvious meaning, notwithstanding it may be thought to make an unreasonable and harsh innovation upon the pre-existing privileges of our own inventors. It is not only the safer course to adhere to the words of a statute construed in their ordinary import, instead of entering into any inquiry as to the supposed intention of Congress, but it is the imperative duty of the court to do so. Where the meaning of the Revised Statutes is plain the court cannot look to the sources of the revision to ascertain whether errors have or have not been committed by the revisers. (United States *vs.* Boyd, 100 U. S., 508.)

There is no practical difference in the phraseology of section 4,887, and that of section 25 of the act of July 8, 1870, from which the section is reproduced. The precise point now raised by the complainant, but made with reference to the effect of section 25 of the act of 1870, was considered by this court in the Gramme Electrical Co. *vs.* The Arnoux & Hochhausen Electric Co., 21 Blatch., 360. It was insisted by the defendant in that case that the complainant's patent expired at the date of the expiration of an Austrian patent, and the complainant took the position that the defense was not tenable because the application for his United States patent was filed before the application for the Austrian patent was made. It was held by Blatchford, *J.*, that the date of the application for the United States patent could not affect the question, and that the meaning of the statute was that the United States patent should expire at the time of expiration of the foreign

patent, irrespective of the time when the foreign patent was applied for.

Judge Blatchford adopted in that case the views of Judge Nixon upon the same question in Bate Refrigerating Co. *vs.* Gillett, 13 Fed. Rep., 553. In the Bate case the question arose under section 4,887, and it was contended that complainant's United States patent did not expire at the date of the expiration of a Canadian patent, because the application for his patent was filed antecedent to the application for the grant of the Canadian patent. The court was of the opinion that it would be wresting the language of the section from its plain and obvious meaning to sustain that position. These decisions have been followed by Bradley, *J.*, upon a subsequent hearing in the Bate case, and by Colt, *J.*, in Bate Co. *vs.* Hammond (First Circuit U. S.).

In view of these adjudications the question should not be considered as an original one. The plea is therefore allowed.

(A copy.)

[L. S.] JOHN A. SHIELDS, *Clerk.*

John C. Tomlinson, Richard N. Dyer, William M. Evarts and *Clarence A. Seward*, for the plaintiff.

Samuel A. Duncan, Leonard E. Curtis, Frederic H. Betts and *Edmund Wetmore*, for the defendant.

THE PHONOGRAPH.

Mr. Edison's improved phonograph was exhibited at the Electric Club House, New York, on the evening of May 12th, before a large audience of club members and their friends. The phonograph was presented by Mr. E. T. Gilliland, in an address, during which he recited some of the steps through which Mr. Edison has developed the instrument as placed before the audience. Mr. Gilliland has been intimately associated with Mr Edison in his experimental work for some years, during which he has given much attention to improving the details of the phonograph.

Mr. Gilliland was followed by Professor Spice, who set forth a few of the acoustic principles involved in the operation of the phonograph, illustrating them by a short series of very effective experiments.

An opportunity was then afforded to every one present to examine and try the phonograph. One was placed in nearly every room in the capacious club house, in charge of Mr. Gilliland's assistants, who courteously and patiently assisted all comers to use the instrument and learn for themselves its powers.

Much improvement has been effected in the apparatus since the phonograph exhibitions of 10 years ago. The improvement is less noticeable in the reproduction of music and set speeches from the platform to the audience, than in the individual use of the phonograph, with its listening tubes, in reproducing ordinary conversation. The gain here has unquestionably been very great.

Though the phonograph may still be thought to come short of a service sufficiently trustworthy and uniform for a considerable commercial use—the startling distinctness with which it sometimes reproduces human speech, indicates that its entire success is but a question of refinement in the apparatus.

Gen. W. T. Sherman, Col. Robert G. Ingersoll, Allen Thorndike Rice, Esq., and other gentlemen of prominence, were among the guests of the Electric Club.

INTENSITY AND CONSUMPTION OF DIFFERENT SOURCES OF LIGHT.

The following are the results of careful measurements; the unit being a standard English candle. The tables are summarized.

PETROLEUM LAMPS.

A number of different lamps were used. The general result was that all the forms had about the same efficiency. The consumption of oil is about 4.5 gramme per candle-power per hour.

Gas burners.	Candle-power mean.	Cubic feet per candle-power per hour, mean.
Ordinary fishtail	17.	.523
Argand	20.5	.410
Auer's incandescent	12.5	.290
Siemens' regenerative, No. 3	66.	.260
" " No. 1	172.	.350
Wenham, No. 2	40.	.230
" No. 4	181.	.160

The argand burner is better than the fishtail; the latter uses nine cubic feet per hour instead of five or six, as is usually calculated, although this is largely a matter of local condition. The Auer incandescent lamp uses only half the gas that the fishtail consumes, but the deterioration of the incandescent material must be added. Of the high candle-power lamps, the Wenham is most economical.

ARC LAMPS (ELECTRIC).

	Mean candles.	Mean candles per horse-power.
Piefer	250	900
Piette-Krizik	820	1,090
Siemens	2,200	1,330

INCANDESCENT LAMPS.

	Mean candles.	Mean candles per horse-power.
Edison (old type)	16	122
" (new type)	16	147
Swan (old type)	16	133
" (new type)	16	157
Siemens	16	169
Bernstein	16	157

MAGNESIUM LAMPS.

These consist of a small clock-work which gradually unrolls the magnesium ribbon, and advances it through the centre of a reflector at a rate which can be regulated to equal that of consumption. From one to eight ribbons can be used. A ventilator is provided for the escape of the fumes produced by the combustion of the metal. The price of the ribbon is nearly five dollars a pound, and this will make the price of 100 candles per hour 16 cents. This lamp can be improved, and the price of magnesium will probably fall.—*Science*

No. of ribbons.	Candles.	Consumption per hour per ribbon for 100 c.-p.
1	3,200	11.14 grams.
2	5,880	14.10 "
4	8,000	14.80 "
6	11,300	14.15 "
8	17,000	14.03 "

POINTERS.

.... THE maintenance account of a plant often defeats dividends.—*William Lee Church.*

.... THE progress of the future will be more and more towards central station lighting.—*J. N. Shoolbred.*

.... THE cost of the best overhead line for an electric railway is about one-tenth the cost of a conduit.—*R. W. Blackwell.*

... WHAT possible avail can it be, if the right thing is not done in the right way, by the right man and at the right time.—*Thomas D. Lockwood.*

.... WHEN we remember that for the price of two horses, and for the working lifetime of two horses, we can work tramcars by electricity; then when we think that it takes 12 horses, the mere question of £. s. d. will carry the day.—*William H. Preece.*

.... COMPARED with the two-wire system, the three-wire system would save about 12 per cent. of the electrical power, with a proportionate saving in the cost of engines and dynamos. It would also effect a considerable saving in the cost of conductors.—*Dr. John Hopkinson.*

.... THE system which offers the highest commercial efficiency will eventually survive against all competitors. The direct system of electrical distribution from the dynamo to the lamp is the only one by which the highest economy and the largest earning capacity can be obtained.—*Thomas A. Edison.*

.... THE hundreds of millions of dollars already invested in the now antiquated systems and wires, will be as much out of place, for all long distance and bulky matter, after the introduction of siliconized copper wires, and the machine system of telegraphing, as an ox-team on a dirt road competing against a steam engine on a well-appointed railway.—*D. H. Craig.*

.... WERE it not for the cost of the dynamos and motors, electricity would supersede to a great extent the use of belts and shafting. . . . . With electricity, the percentage of power lost in the transmitting medium becomes smaller as the amount of power transmitted is reduced, which is exactly the converse of what happens with belting and shafting.—*William Giessel.*

.... THE magnitude of the commercial interests which have been called into being by physical discoveries and the development of new ideas, indicates that if the progress of the past few years is to continue—if new achievements are to rival those of the past, it must be by a higher education and training, not of a few men, but of the many, so that no germ of talent shall miss its opportunity for development and its chance for increasing the powers and resources of man.—*Chauncey Smith.*

THE HEATING EFFECTS OF ELECTRIC CURRENTS.[1]

I have taken a great deal of pains to verify the dimensions of the currents as detailed in my paper read on December 22d, 1887, required to fuse different wires of such thicknesses that the law

$$C = ad^{3/2}$$

is strictly followed; and I submit the following as the final values of the constant "a" for the different metals:—

	Inches.	Centimeters.	Millimeters.
Copper	10,244	2,530	80.0
Aluminum	7,585	1,873	59.2
Platinum	5,172	1,277	40.4
German silver	5,230	1,292	40.8
Platinoid	4,750	1,173	37.1
Iron	3,148	777.4	24.6
Tin	1,642	405.5	12.8
Alloy (lead and tin 2 to 1)	1,318	325.5	10.3
Lead	1,379	340.6	10.8

With these constants I have calculated the two tables given below, which I hope will be found of some use and value.

wire which had fallen across the electric light wire. The amount paid was $3,500.

On May 14th, the Supreme Court of the United States denied the motion for a rehearing of the Bell telephone case, the motion having been made by the counsel for the People's (Drawbaugh) Telephone Co.

The telephone strike at Rochester, N. Y., which was inaugurated November 20, 1886, has been ended, and the people of Rochester will again enjoy the benefits of a telephone service, of which they were deprived by their own acts. A compromise has been effected, the telephone company agreeing to abandon the "toll system," the proposed adoption of which was the principal cause of the strike, and the subscribers are to pay a "flat" rate somewhat higher than that formerly charged.

.... THE position of a fireman may be considered an humble one by some folks, but he is a man for all that, and his pride in what he can do is a stronger spur than anything else. . . . . But eventually you must pay him what he is worth. If not, someone else will be glad to have him.—*Jarvis B. Edson.*

THE TELEPHONE.

Judge Don A. Pardee, of the United States Circuit Court, at New Orleans, recently rendered a decision on final hearing in the case of the American Bell Telephone Co. et al., *vs.* the National Improved Telephone Co., in equity. The court decides that the telephones used by the defendants are an infringement on the Bell patents, and orders that all such instruments be delivered to the clerk of the court, subject to further orders, and gives the complainants judgment against the defendants for all costs, charges and disbursements in this suit. William Grant is appointed master to ascertain costs and damages.

The Bell Telephone Co., of Buffalo, N. Y., has settled with the heirs of James F. Norton, the colored man who was killed some ten weeks ago while attempting to rescue a horse from a telephone

1. W. H. Preece, in *Industries.*

AN INTERESTING PATENT SUIT—DOUBLE CARBON ARC LAMPS.

The suit commenced recently in the United States Circuit Court at Chicago, by George H. Seeley and others against the Brush Electric Co., and another for alleged infringement of the patent of Matthias Day, 1874, on arc lamps will be watched with much interest, and perhaps some concern, by arc lamp manufacturers. Claim 1 of Day's patent is as follows: "In an electric light the combination with each electrode holder and one electrical circuit of two or more electrodes substantially as and for the purpose set forth."

The Western Electric Co., of Chicago and New York, are owners of an undivided half interest in the Day patent and take a leading part in prosecuting the present suit. The joint owners of the patent ask for an accounting and an injunction against the defendant company.

ELECTRIC LIGHT AND POWER.

In the United States Circuit Court, in New York, Judge Wallace rendered an important decision recently in favor of the defendants in 26 suits for infringement of patents brought by the Edison Electric Co. against the United States Electric Lighting Co. The suits were instituted about three years ago and related to certain alleged infringements on patents for incandescent lamps, dynamos and other electric light apparatus. The defendants' counsel took the position that the Edison patents could not be infringed for the reason that they had expired. Judge Wallace allowed this plea to the bills of complainant.

THE suit of the Brush Electric Co. against the Western Electric Light & Power Co., of Toledo, Ohio, for infringement of Mr. Brush's double carbon arc lamp patent of 1879, is still going forward.

AT ELIZABETH, N. J., the arc-lighting system was temporarily disabled by a lightning stroke during the thunder storm of Monday night, May 28th. Every lamp was extinguished.

THE CHICAGO ARC LIGHT AND POWER CO. are now operating one of the most extensive systems in the world—about 1,500 arc lamps being lighted every night. The *Western Electrician*, of Chicago, for May 5th, contains a fully illustrated description of the main station of this company at Washington and Market streets.

REFERRING to a rumor that the Edison company contemplates the raising of the standard voltage of the Edison system from 220 to 330 volts, *The Electrician*, London, says:

"On this point we are enabled to add some further information derived from an independent and thoroughly authentic source. It appears that about twelve months ago several important local companies working the Edison system in America found that they had practically arrived at the end of their tether—that is to say, they had completely covered the ground within the limits of the three-wire 220-volt system, and, unless they could extend the economical radius of distribution, the output could not be further increased. Whether or not they had in all cases arrived at the limit of 20,000 lamps, which Mr. Gordon holds to represent the maximum economical output for a single station, we cannot say, though a maximum current of 9,000 amperes mentioned by our correspondent represents about 36,000 lamps, and might mean nearly 50,000 wired. However this may be, it appears that under the aforesaid circumstances a strong disposition was shown to introduce alternating currents for the supply of the outer circle, and a memorial was presented to the parent company in favor of such a step. But although the movement was strongly supported by several of the leading men connected with the system, Edison himself set his face against it from the first. We may believe that it was this agitation which recently led Edison to rake up his earlier patents with motor-generators, and to lay down the experimental plant of this type, which is now running at Llewellyn Park. We have yet to learn how much success the latter system has attained, but it is tolerably evident that it has not yet emerged from the experimental stage. It is also evident that Edison has succeeded in stemming the movement which had set in amongst his supporters in favor of alternating currents. Probably the enormous increase of business from the transmission of motive power had also a good deal to do with the decision to stand by the continuous current."

ACCORDING to the *Revue Scientifique*, the most advantageous thickness of carbon for arc lamps, taking the currents specified, is given in the following table:—

Current in amperes.	Diameter of carbon in millimeters.
2 to 3	2
3 to 5	4
4 to 6	5
7 to 10	7
10 to 11	9
11 to 15	10
12 to 16	11
13 to 20	12
15 to 21	13
16 to 25	14
25 to 30	15
30 to 45	17
35 to 60	18
40 to 80	20
50 to 120	25
80 to 180	30

For heavy currents, our contemporary recommends bundles of carbon rods of 4mm. diameter or fluted carbon rods.

Foreign.

Austria.—Considerable progress is being made in various Austrian towns with electric lighting. The total number of glow lamps now installed in Vienna may be estimated at eighteen thousand, and in addition there are about one thousand arc lamps in use. One of the most complete installations in Bohemia is that on the Sophieninsel, in Prague, an island on which is a casino used for public entertainments. This installation has been erected by Herr Krizik, and consists of three Otto gas engines, each of 50 h.p., and a small gas engine for starting the big engines. There are four disc dynamos, each capable of supplying four hundred lamps. In the assembly rooms of the casino there are fixed five arc lamps, and nine hundred glow lamps; but as there is current to spare, some street lighting by arc lamps will be done from these dynamos. The whole of the plant for this installation, including the handsome electroliers, has been manufactured and supplied by Herr Krizik, who is also the contractor for the lighting. The light is paid for, not by the amount of current consumed, but by the amount of gas consumed in the engines, the charge varying from 20 kreuzer to 32 kreuzer per cubic meter, according to the number of lamps in use at a time. The gas for the engines costs 9½ kreuzer per cubic meter, or about 4s 9d. per 1,000 cubic feet, so that the contractor for the electric light receives a surplus of about 7s. on every 1,000 feet of gas required, and this covers his profit, the payment of wages, lamp renewals, carbons, and other charges standing against the installation.

Belgium.—The annual report of the administrative council of the Tramway Company of Brussels, states that the working of three cars electrically during 1887, has resulted in a loss of $3,000. The service was commenced on the 17th of April, 1885, with one car running between the Place Royale and the Rue Belliard. A second car was run on the 8th May, and a third on the 19th September. These cars are at present running in the Rue de la Loi. The electric cars covered last year 34,500 miles. The financial failure, although not officially so stated, is thought to be due to the rapid wearing out of the accumulators. The depreciation of these is calculated at 22 centimes per kilometer—or say 6½ cents per car mile; and as this estimate does not allow for general charges, nor for the cost of power, it is evident that the total working expenses must be considerable. The destruction of the plates is ascribed to the continual surging of the acid among them, coupled with the vibration to which the cells are exposed. M. Julien proposes to remedy the defect by placing a number of rubber rings round the plates, the rubbers to act as separators, and at the same time to subdivide the acid into smaller quantities, and so limit the surging action.—*Industries.*

The Molière Theatre at Ixelles, a suburb of Brussels, is entirely lighted by electricity, small glow lamps being used in the auditorium, on the stage, and in the rooms, and an arc lamp being placed in the chandelier. The atmosphere of the house has been much improved since gas was done away with. The price charged for the electric light is the same as was previously paid for gas. The generating plant is placed in the basement at the back of the theatre, a 35 h. p. Meunig engine and two Thomson-Houston dynamos being employed. Steam is supplied from a De Naeyer boiler.

England.—Lords Crawford and Wantage, Sir Coutts Lindsay, and others, have boldly thrown down the gauntlet to the gas people. They have taken ground at Deptford, for a central station, and are going to supply electricity to London. They start with 200,000 lamps, and charge at the same rate as gas at 4s. 2d. per 1,000 cubic feet.

Professors Ayrton and Perry have satisfactorily disposed of the question as to whether there is any difference in the light emitted by a glow-lamp when incandesced by alternate or direct currents. They find no difference. The same power (3.39 watts) applied gives the same light (one candle) in each case.

Germany.—The following relative figures of the cost of the production of 1,000 watt-hours, the unit of electrical energy introduced by the board of trade, are given by Peukert in the *Centralblatt für Electrotechnic*:

	s.	d.
Thermo-electric battery (gas)	33	4
Bunsen battery	3	2
Daniell "	2	2½
Dynamo (gas)	0	6¼
Dynamo (steam)	0	2½

Scotland.—THE BRUSH PLANT AT THE GLASGOW EXHIBITION.—The electric lighting plant of the Glasgow International Exhibition, supplied by the Anglo-American Brush corporation, is said to be the largest ever installed in connection with any exhibition. Nine large boilers drive engines of various kinds, and produce lights equal to over 1,000,000 candles. In the principal structure there are 437 arc lamps of 2,000 candles each, while in the art galleries there are 40, and in the grounds 70 lamps of similar illuminating power. In the dining rooms there will be 750 16 c. p. incandescent lamps.

PERSONAL MENTION.

MR. T. CARPENTER SMITH has resigned his position in the Allegheny County Light Company, of Pittsburgh, Pa., to go into business as one of the firm of M. R. Muckle, Jr. & Co., at No. 608 Chestnut street, Philadelphia, mechanical and electrical engineers and contractors. Mr. Smith has made an enviable record as an electrical engineer, and in his new connection will doubtless find scope for his talents in a more extended field.

MANUFACTURING AND TRADE NOTES.

THE SPRAGUE Co. have just received orders for a number of motors to be shipped to Paris. They report large sales of standard motors for the last two weeks. Mr. F. B. Thurber, of the wholesale grocery house of Thurber, Whyland & Co., New York, expresses entire satisfaction with the elevator service recently installed in their place by the Sprague Electric Railway and Motor Co. The service is regarded as not only good but cheap.

Among orders recently received by the company is one for a large number of motors to be used in the new marble building of A. J. Drexel, Philadelphia. The average power of the motors is about 7½ h.p.

Another order just completing is an installation of electric motors at the "Ophir Farm," White Plains, N. Y., the country residence of Mr. Whitelaw Reid. The motors are to be used for pumping water, stable work, and other purposes.

J. F. BAHR & Co., well known as manufacturers of electrical apparatus, have removed from 108 Liberty street to No. 38 Dey.

MESSRS CHAS. A. SCHIEREN & Co. report recent sales of leather link belting to the following parties, for use on dynamos: Home Electric Light Co., Tyrone, Pa.; Narragansett Electric Light Co., Providence, R. I.; Scranton, Ill. Heat and Power Co., Scranton, Pa.; Thomson-Houston Electric Co., Lynn, Mass.; Sheffield Electric Light Works, Sheffield, Ala.; Circleville Edison Electric Ill. Co., Circleville, O.; Lima Electric Light and Power Co., Lima, O.; Chester Electric Light Co., Chester, Pa.; Virginia Electric Light and Power Co., Richmond, Va.

THE UNION SWITCH AND SIGNAL Co. has made a new departure in the manner of supplying interlocking and signaling apparatus. Heretofore, the company has contracted to supply not only the special parts made at its works, but has contracted to supply the labor to erect the work ready for operation.

The managers of several railroad companies have requested them to bid on material delivered f. o. b. cars, and to furnish competent superintendents of erection, pointing out that they can utilize their ordinary labor for the work of erection, and thus make the total cost much less than it has heretofore averaged.

Hereafter all bids of the company will be for material with superintendence, except when for special reasons the apparatus erected complete, ready for work, is desired. In such cases, two bids will be made, one for the material only, and the other for the erection.

Mr. Henry Snyder has been appointed general manager of this company, succeeding Mr. C. R. Johnson. Mr. E. H. Goodman, who was connected with the Pullman Palace Car Co. for eighteen years, and since August 1886, as second vice-president, has been appointed assistant general manager and general agent.

HOLMES, BOOTH AND HAYDENS, manufacturers of bare and insulated copper wires, issue in very convenient form a pamphlet of note-book size, containing, along with other useful information, a table of maximum safe carrying capacity of bare copper wire, arranged by Mr. H. Ward Leonard, electrical engineer, of Chicago. On the page facing the table Mr. Leonard has placed a chart, with the curve of safe-carrying capacity, the whole making a valuable addition to an electrician's pocket book.

THE STANDARD UNDERGROUND CABLE Co., Pittsburgh, Pa., have issued a new price list (No. 5) of Waring cables, weather-proof line wire, &c. Convenience is afforded to customers by the columns showing approximate feet per pound and approximate weight per 1,000 feet in the list of weather-proof line wire. Important and desirable details are shown in the price list of electric light cables, in which are given first, the B. and S. gauge number and then the diameter of solid copper wire, also the area in circular mils, and the nearest approximate equivalent in Birmingham wire gauge, also the weight per foot of cable and the diameter of the same.

ELECTRIC STREET RAILWAYS IN AMERICA

Now in Operation.

ABBREVIATIONS.—**mi.**, miles of single track; **g.**, gauge; **lb.**, pounds rail per yard; **m.**, electric motors; **c.**, cars; **m. c.**, motor-cars; **h. p.**, horse-power; **T.**, T rail. Name of electric system used is in SMALL CAPITALS.

Worcester, Mass.—Worc. & Shrewsbury—(To be changed from steam to electricity); 2.7 mi.; g. 3; overhead cond. DAFT.

Notes.

THE MAIN ELECTRIC MOTOR is to be tried on the Fort Hamilton line of the Brooklyn City Railway Company.

AT COLUMBUS, OHIO, a 250 h.p. plant is being erected, intended to operate fifty street cars on ten miles of double track on the short series system. Charles F. Brush, of Cleveland, is said to be largely interested in this enterprise, and it is understood motors designed by him are to be used.

THE HARTFORD AND WETHERSFIELD RAILWAY COMPANY propose to use electricity on its line.

ELECTRIC RAILWAY enterprises are on foot in the following places:—Hudson, N. Y.; Huntington, W. Va., Montreal, Canada; Modesto, Cal.; St. Augustine, Fla., and Tiffin, O.

THE PEOPLE'S PASSENGER RAILWAY COMPANY, of Philadelphia will place a Wharton electric motor car, 22 feet in length with double trucks, on the 4th and 8th street line.

THE J. G. BRILL COMPANY, of Philadelphia, is building six electric storage battery cars for William Wharton, Jr., and ten for the Fourth avenue line in New York.

ALL the electric railway construction companies report rapidly increasing business in every direction, and important contracts are being closed almost daily. There is little doubt that the mileage of electric railways in the United States will be doubled, if not tripled, before the end of this year.

THE electric equipment furnished by the Sprague Electric Railway and Motor Company to the Richmond Union Passenger Railway has proved to be one of the most successful, as it is the most extensive undertaking of the kind in existence. The topography of the city rendered the project a very difficult one to carry out, and it gives us pleasure to record that the equipment has been accepted by the company, and that its operation is in the highest degree satisfactory. Forty cars are now running from one central station, and the total motive power expenditure, both in the central station and on the road, including depreciation and everything except executive expenses, proves to be only 4.32 cents per car mile. The cars are crowded with passengers, and the financial success of the scheme has been immediate and beyond anticipation.

C. J. VAN DEPOELE is now at the Lynn factory of the Thomson-Houston Electric Company, perfecting the details of electric railway motors.

THE trial trip of the Ansonia Electric Railroad was made April 30th. This is a freight as well as a passenger line, and the result of the experiment of hauling heavy freight cars by electricity will be watched with interest.

IT is reported that the Thomson-Houston Electric Company will introduce its electric conduit system on the line of the West End Street Railway Company between Cambridge and Newton, Mass. President Whitney is making a careful examination of the system.

THE SPRAGUE ELECTRIC RAILWAY AND MOTOR CO. have just moved into their new and capacious offices, 16 and 18 Broad st, N. Y., with increased facilities for the accommodation of their friends and customers.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From April 24 to May 15, 1888 (inclusive).

Alarms and Signals:—*Electric Signaling Apparatus*, M. W. Parrish, 381,576. *Electric Alarm for Ships' Compasses*, A. Gross, 381,698. *Annunciator and Signaling Apparatus*, M. EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VII. NEW YORK, JULY, 1888. No. 79.

By arrangement with the ELECTRICAL WORLD *of New York and with* THE WESTERN ELECTRICIAN *of Chicago, the publishers are enabled to offer either of those weekly journals, together with* THE ELECTRICAL ENGINEER, *for one year to new subscribers for* $5.00, *or the three journals for* $7.50.

THE COMMERCIAL ASPECT OF ELECTRIC LIGHTING.

THE record of litigation in connection with important patents relating to electric lighting, has been, so far as this country is concerned, a singularly disastrous one for their owners. The attempt of Siemens to obtain a patent, which if successful, would virtually have controlled the manufacture of the modern type of dynamo machines, was frustrated by his delay in making application until one of the machines had been two years in use in the United States. The Gramme syndicate were defeated in their efforts to place themselves in a similar position, by reason of the expiration of a prior foreign patent for the invention. The Brush company brought a suit to enforce its patent on the arc lamp, and after a protracted and expensive legal contest, was defeated by the production of evidence of an actual, though limited, prior public use. And now the Edison incandescent lamp patents appear to be doomed to share the fate of their unfortunate predecessors.

As a result of this state of affairs, the public has enjoyed what has been practically an era of unrestricted competition in both arc and incandescent lighting, for some 10 years. But contrary to the general opinion, indications are by no means wanting that the present condition of things is likely to undergo a material change at no distant day. A combination or consolidation of electric lighting interests has often been discussed, and sundry attempts have been made in the past to realize it. But the combined resistance of the innumerable personal interests which would be affected by such a move has been far too great to permit much real progress in the desired direction to be made. Meantime the stockholders of the electric light companies, as well as the public, have gradually become more and more disgusted with the present outlook. Only a very small proportion of the vast sums of money embarked in electric lighting enterprises has yielded any return whatever, and it is becoming painfully evident that the bulk of the investment must sooner or later be charged to the account of "profit and loss." On the other hand the public is badly served; many plants are becoming dilapidated, and the catalogue of disasters to life and property is lengthening with ominous rapidity. There exists in fact, an exact reproduction of the state of affairs which existed in the telegraphic service 30 years ago, and as surely as history repeats itself, so surely the same remedy will be applied, consolidation or union of interests. Such a consolidation will not come voluntarily; it can only be brought about, like the welding of metal, by the combined effects of internal heat and external pressure. Many considerations, some of which are of a commercial and others of a legal nature, indicate that the beginning of the end is not far distant. However well-founded the public antipathy to monopolies may be, it must at least be affirmed of an electric light monopoly, that it is so closely hemmed in by its great rival, gas, that no fear of extortionate charges need agitate the mind of the prospective consumer. But the history of the consolidation of the telegraph interests clearly shows that the real source of future profit lies in the reduction of expenditure and in the increase of the business. Every one knows that the money received in the electric lighting business to-day would yield a very large profit, if all unnecessary expenses were abolished. That the force of circumstances must ultimately bring about the result we have pointed out, in spite of all opposition on the part of persons interested in preventing it, seems to us as certain as any future event can be.

A SERMON FOR THE TIMES.

THE absurd story published in the newspapers a few days since, with the usual pretentious accuracy of detail, to the effect that a woman had been paralyzed by an electric shock while riding in one of the cars of the Brooklyn and Jamaica electric railway, is an example of the senseless prejudice with which the public mind has become saturated in respect to the use of the modern conveniences of life in which electricity is coming to take a prominent part. Everybody has laughed over the story of the destruction of the telegraph lines in Alabama some years ago, by a mob of ignorant and superstitious people, who believed the wires to be the cause of the dry weather which had destroyed their crops and deprived them of their means of subsistence. Yet it is difficult to comprehend wherein the intelligence of the average newspaper editor, or reader, for that matter, is so very much in advance of the "pore white trash" of Alabama in this particular respect.

But, when we undertake to account for this state of affairs, which forebodes an infinite amount of trouble and

expense in the future for electrical enterprises, we are met with the astonishing fact, that it has been sedulously and persistently inculcated by the electrical people themselves, and that as a matter of fact, it is wholly due to what in plain terms must be characterized as the criminal and reckless mendacity which has been indulged in without stint by the short-sighted officials and advertising agents of certain electrical companies, for the purpose of creating prejudice against the systems and apparatus of their business competitors. Of course this silly and senseless policy could have but one effect, that of inspiring the public, which as a rule is incapable of distinguishing dynamos from dynamite, much less one electrical system from another, with an unreasonable and childish terror of all electrical appliances whatsoever.

We might go into particulars and give a long list of offences of this kind, in the way of authorized publications which have been scattered broadcast, and which are filled to repletion with the most barefaced and unblushing falsehoods, misrepresentations and insinuations respecting the systems and apparatus supplied by their business competitors.

We cannot however refrain from particular mention of one publication of this character relating to electric railways, which came into our hands a few days since, and which might well cause Ananias, were he still living, to hang his head for very shame, to think of the vast possibilities in his peculiar line of ability which he never even so much as conceived of. In view of the number, the boldness, and the ingenuity of the lies which bristle from every line—we had almost said every word—of this incomparable production, we must in all kindness advise the authors of "Death in the Air," the "Fire Cracker," and even that recent convert from high-tension heresies, who in the columns of the *Evening Post*, is enlightening the public in respect to the "damnable" character of the alternate current, to cork up their ink-bottles and retire from the field. There is a fertility of resource, a picturesqueness of statement, a wealth of argument, and a mastery of statistics, exhibited in the work of the railway man, which even an university education and a long residence west of the Missouri river, seems utterly inadequate to account for. Seriously, every one interested in electrical industries should use his efforts to put an end to this state of affairs, alike useless, discreditable and harmful to all electrical interests. Whether justifiable or not in its original application it is certainly true in this connection, that the "injury of one is the concern of all."

TRYING IT ON THE DOG.

A PROMINENT electrician of this vicinage, who has not yet reached that stage of development which permits him to see a legitimate field of usefulness for any species of electricity the E. M. F. of which exceeds 110 volts, was recently appealed to by a reportorial representative of one of our esteemed daily contemporaries for information respecting the *modus operandi* of capital punishment by electricity. With his customary urbanity the electrician at once volunteered, in the true scientific spirit, to try it on a dog,—a yellow dog. We can almost see the childlike and bland smile of the experimentalist as he proceeded to prepare an electric current—an *alternating* current, as the reporter was carefully instructed to inform the public—of between 1,000 and 2,000 volts potential, which was duly administered to the unfortunate cur, with results too shocking to admit of being narrated here. This leads us to remark that if it were only possible—and perhaps it is possible—to educate public opinion up to the point of demanding legislation which should render compulsory the use of direct currents for lighting and other industrial purposes, and of alternating currents for extirpating criminals and other creatures whose room is considered preferable to their company, there would be little further occasion for the services of a certain electrical "literary bureau" whose efforts in the dissemination of useless misinformation have been prosecuted with a zeal and industry worthy of a better cause.

ANOTHER RICHMOND IN THE FIELD.

"I AM in the arena to fight these claims to the end, and warn all parties against entering into contracts with companies or persons offering the long-distance system of incandescent lighting by the alternating converter system for sale."

Thus energetically, not to say truculently, ends a letter dated April 28, 1888, which we received from Walter K. Freeman, electrical engineer, soon after its date. It was apparently a circular letter, and in it Mr. Freeman claimed "solely and absolutely" to be the inventor of the "alternating or converter system of electric lighting." The letter was designated "No. 1," and the author promised that No. 2 would "explain Mr. Red Book's position relative to the incandescent electric lamp." We have awaited No. 2 with interested expectancy, but, so far, in vain. Mr. Freeman is reported to have allied himself recently with the Fort Wayne Jenney Electric Light Co. We trust that engagement will not prevent his completing the series of letters fairly promised in his initial communication.

THE systematic and complete removal of dead wires from the streets of New York is the most obvious and needed step towards reducing present risks to life and property, and for improving the electric service of the city. No one knows how great a mileage of unused conductors a thorough examination of the lines of the telegraph, telephone and electric light companies, together with those of the police and fire alarm systems, would reveal; but it would scarcely prove less than some "thousands of miles," to use the words of Mr. W. L. Strong, president of the Brush Electric Illuminating Co. as reported in an interview recently published by the *New York Herald*. Here is a present danger and constant menace—concerning which there can be no difference of opinion among electrical engineers—easily and immediately removable. We have a board of electrical control. Must the dead wires remain until we have had a few more "accidents?" Apparently not, we think, since the appointment of Mr. Schuyler S. Wheeler, June 15, as electrical engineer to the Board, gives assurance that, so far as he is concerned, immediately practical measures for the improvement of the electric systems of the city will have prompt and intelligent consideration and action. We understand that Mr. Wheeler has already initiated a campaign against the dead wires.

VERY significant of the estimate placed upon the conduits provided by the politico-histrionico-legal subway commission of this city, now called the Board of Electrical Control, is the following paragraph from Mr. Strong's remarks reported in the *Herald* interview mentioned before.

> To show you that our company are ready and willing to comply with the law, I mention that we were about to sign a contract on November 1 last for a nine wire cable, which we intended to lay in the conduit along Broadway, from Fourteenth street to Thirty-fifth street. The makers were to guarantee the wire for five years, and were to give a bond to that effect. They asked time to examine the conduit, and when they had done so they came to us—five days later—and withdrew their guarantee. I am not at liberty to tell you why they withdrew it, but you can draw your own deductions. After this refusal we made an investigation on our own account and found that even if we had laid the wires we could not have made house connections without extra expenses that would soon have bankrupted us.

TUESDAY evening, June 19, Mr. F. J. Sprague read a paper on the "Solution of the Street Railway Problem," before the Institute of Electrical Engineers, at the Library building, Columbia college. We regret that it has not been found practicable to supply copies of the paper in shape for printing to the electrical journals in time for its appearance in this issue of THE ELECTRICAL ENGINEER.

After some general discussion of the difficulties to be encountered and surmounted in street-car traction, Mr. Sprague described the electric motor system now in use on the lines of the Union Passenger Railway Co., Richmond, Va.; in the construction and operation of which many very serious problems had been met with. It would hardly be proper to make extended comment in advance of the publication of Mr. Sprague's paper. It is sufficient to say that his account of the successful accomplishment of difficult tasks on the Richmond lines, particularly the climbing of steeper grades than have been thought practicable for self-propelled cars, implies a most promising outlook for a continued and accelerated growth of electric railroading in city streets. Mr. Sprague illustrated his descriptions with a large number of admirable photographs, projected on the lecture room screen by the new lantern presented to the Institute by its president, Mr. Edward Weston.

THE "alderman business" is proving quite as serious an obstacle to electric street railway enterprise in this city as the competing horse and cable systems. The scientific objection of the aldermen to storage battery cars, to wit: the danger apprehended from "accumulations" of electricity, still stands in the way of a permit to use on Fourth avenue the cars contracted for with the Julien Electric Co. Notwithstanding the considerable delay that will doubtless attend the process of illuminating the aldermanic mind on the electrical questions involved, we are glad to know that the promoters of the project are confining their efforts to that point, and evince no disposition to "talk business" with aldermen or their representatives.

THE North and East River Railroad Co.'s troubles are of much longer standing, and are due to obstruction by the Bleecker Street company, the present owners of which decline to carry out a verbal agreement to give the North and East River company, the use of about 1,000 feet of their track in Fulton street, which the late Jacob Sharp is said to have made soon after the formation of the latter company. The North and East River company, as our readers will remember, own a charter (under the Cantor Act) to run an electric railroad through Fulton street from river to river connecting Brooklyn and Jersey City ferries. The Bentley-Knight conduit system was adopted and the company began construction, purchased equipment, and would probably have been prepared to run its cars last October but for the failure of the Bleecker Street company to come to terms. Legislative relief was sought but was defeated in the Senate, and the dead-lock continues. As under the Cantor Act, the North and East River company must pay to the city over one-third its gross receipts, while the Bleecker Street company pays nothing, and as the public need of a cross-town line in Fulton street is obvious to all, it will be seen that the Bleecker street company is not only blocking the operation of an electric railway, but standing in opposition to manifest public interests.

IN the suit of the American Bell Telephone Co. against the Cushman Telephone Co., the evidence having been taken during an extended period, argument was begun before Judge Blodgett, at Chicago, June 4th, and concluded June 9th. The complainant's argument was made by Mr. Geo. L. Roberts and Mr. B. F. Thurston, and that of the defendant by Mr. C. D. F. Smith and Mr. J. L. High. The case has attracted much attention and interest, particularly in the west, where Cushman claims to have made his "talking boxes" some thirty odd years ago. He far outstrips Drawbaugh in his allegations of priority, claiming to have discovered the principles of the telephone in 1851 at Racine, Wis. Unless Cushman's narrative and testimony prove better able to bear legal and judicial analysis than did those of the more modest Pennsylvania anticipator, we may shortly expect another important judgment sustaining the Bell patents.

IN view of the large extent of arc lighting in this city—Mayor Hewitt's recent investigation showing that there are some seven thousand arc lights in use, while there have been but four fatal casualties since their introduction ten years ago—it is quite true that the industry is carried on with less danger to life than many others not usually deemed especially hazardous; but comparative immunity ought not to be pleaded in abatement of the demand for every safeguard known and possible of application.

THE New York *World*, in its issue of June 11, gave the names of 21 citizens who had been run down and killed by reckless drivers in the streets of New York since January 1, 1888, not to mention 130 more who have been more or less seriously injured from the same cause. During the same period of time two citizens have been killed by electric wires in the streets.

.... IN any system of electrical distribution, the greatest economy is attained when the cost of the energy lost in heating the wires equals the interest on the cost of the copper.—*Sir William Thomson.*

OBSERVATIONS.

AWAY back in the fifties the observer remembers of hearing his grandfather speak of a friend who was killed by a "thunder-bolt."

This term we don't often see now, nor indeed is it much used except by poets, who have a license and use it, and by the penny-a-liners of pink evening newspapers.

When thunderbolts are mentioned, one is reminded of the old notion that existed before Wall speculated upon, before Gray asserted, and before Franklin demonstrated the identity of electricity and lightning; the old notion that something solid and intensely hot, passed along the track of a lightning flash, and buried itself in the ground. Perhaps this notion arose from the concurrent influence of two classes of phenomena. When lightning strikes the ground it often bores a hole of considerable depth, which is found to be lined with a slag of vitrified sand. This presents no difficulty. But *aerolites* are sometimes found in the holes which they have made, still intensely hot, as a result of their rapid passage through the, to them, unusual density of our earthly atmosphere. A hasty generalization seems to have connected these two absolutely unrelated phenomena, and the supposititious thunderbolt is thus accounted for. The proverb about a lightning flash from a clear sky may also be accounted for by the occasional visit of these strangers from a strange land.

These observations were all suggested by a stray expression come upon the other day in Carl Hering's new book, which by the way, considered as a whole cannot be overpraised. On page 12, if memory is correct, we find the expression "bolt of lightning." It is doubtless intended merely as an equivalent phrase for "a stroke" or "flash of lightning," and may be equally proper; but a little thing will sometimes start a train of reflection, and it was Mr. Hering's "bolt of lightning," that caused the above bolt of thunder.

• • •

THE subject of thunder and lightning "bolts" affords an excellent opportunity to slide off into a second observation, which is that Mr. Delany's paper on the "Protection of the Human Body from Dangerous Currents," read before the Institute of Electrical Engineers, May 16th, was most timely and valuable. The truth brought out in the discussion, that both electromotive force and quantity are required to shock fatally a human being, is worth everybody's while to know; as is also the fact, which curiously enough few persons, even of large experience seem to appreciate, that lightning possesses in addition to its enormous electromotive force, considerable volume. It is true that Faraday and H. W. Spang are at swords' points here; but Spang is, upon this issue, in the right of it. It is to be hoped that Mr. Delany's plan of shunting will be successful.

The observer owns to a faint preference in favor of first "trying it on a dog" or perhaps some animal of a larger size, and also to a hope that Mr. Delany will not try it himself with a dangerous current, without first adopting some similar precaution; for while it is certain that Ajax Delany defying the lightnings, would be an impressive and instructive spectacle, and one well worthy of the pen of a Homer or the pencil of a Paul Veronese, he is altogether too valuable a man to lightly risk his life, e'en though it be in the cause of science.

• • •

CLOSELY allied to the electro-medical spectacles, which the observer commented upon last month, is a "*Headache Curing Hat*" which forms the subject-matter of a later patent, No. 383,899.

An ordinary "Derby" has two flat cases, one made of copper, the other of zinc placed inside its lining; one case is secured in the front of the hat, the other in the back. The cases are perforated, and hold absorbent material like woolen cloth which is saturated with dilute acid. The two cases are united by an insulated wire which runs round the interior of the crown of the hat. The perspiration is stated by the patent to be absorbed by the woolen material and to aid in generating the electricity. The wearing of this hat is warranted to relieve headaches. Very likely it will by the aid of "Christian Science," but will it not be equally competent to produce a headache if worn by a person who has not one ready made? As to the perspiration, it is quite conceivable that anyone wearing such a hat will indeed perspire freely.

• • •

AND while on the subject of patents, it may not be out of order to record that an electrical invention of universal interest was patented on May 29th, 1888 (see U. S. patent No. 328,485), to one A. C. Palmer. We have had neither time or opportunity to accord this invention the study it obviously deserves; but there can be no doubt that the "Electric Punch Register" (this being the modest but descriptive title of the invention) will meet a long felt want. "Punch, Brothers Punch with Care." Since writing the above we have been harassed by the feeling that, possibly the Punch we have been thinking of, may not be the Punch which is to be registered.

• • •

THE application of the telephone as a substitute for the galvanometer in electrical measurements with the Wheatstone bridge has often been alluded to in technical journals, and seems to have lately furnished a subject for some discussion in the electrical newspapers of England and the United States.

It may be of interest to note that apparently the first published suggestion of such a use is to be found in a communication by Herbert Tomlinson to *Nature*, March 14th, 1878.

• • •

THE "Spirit of '88" prevails even in political convention despatches. We are assured by Associated Press despatches, that "*Chicago is like a battery or a dynamo, sending out a magnetic current in every direction.*" It appears that Chicago is preserved from the alleged infringement of Mr. Edison's blanket mortgage on the distribution of electrical energy only by the fortuitous but lucky circumstance that the currents it evolves are not electric but magnetic.

• • •

UNDER the legend, "Bury your Watch," the Boston *Herald* of June 6th, reproduces an item of news written from Connecticut to the New York *Sun* by one of its correspondents. It appears that a homœopathic physician of Ansonia discovered to his sorrow —what others before him had found out—that evil communications, of a magnetic nature, corrupt good watches.

His remedy was novel. Inclosing the wayward watch in a cloth bag, he buried it in a box of earth. It remained there three days, and in 27 hours from the time of its disinterment it had turned neither to the right hand nor to the left, except in the accomplishment of its ordinary and legitimate work; to adopt the exact language of the correspondent: "It has not varied a hair."

The reporter naturally remarks on the simplicity of the remedy, and reviles the jewelers who have foolishly been using demagnetizers and anti-magnetic appliances vouched for by the eminent of the electrical profession. Our *Alma Mater* is surely verifying the words of the many writers who pronounce her "a great magnet," and her children are to be congratulated that even a small portion of her —in a box—is able to counteract with *its* magnetism, that of the machines that send forth their light by night and their power by day.

POINTERS.

.... IN reality, all machines are alternate current machines, the currents appearing continuous only in the external circuit during their transit from generator to motor.—*Nikola Tesla.*

... NOTHING can now permanently check the growth of the telephone, the telegraph or the electric light. They have become necessities of our civilization, and any hasty or ill-advised enforcement of the law to convert all aerial to underground systems which should result in serious injury to them, would prove the surest way to perpetuate the nuisances of overhead wires and poles in the streets.—*Professor G. W. Plympton.*

.... I CANNOT regard a lightning flash as an example of a small current. The heating effects which are present in such cases are sufficient to show that the current may rise to very many hundreds of amperes.—*Elihu Thomson.*

.... AFTER 25 years of the most careful study of the street railway problem, I am convinced that the motor of the future is steam.—*Louis Ransom.*

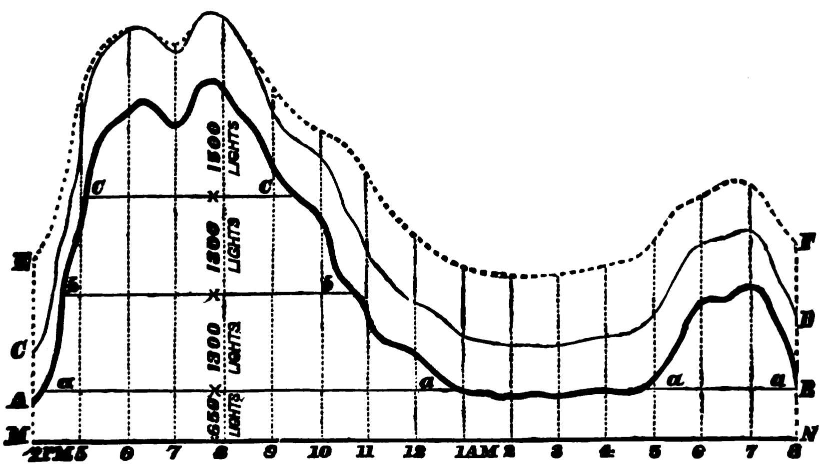
ARTICLES.

HIGH AND SLOW SPEED ENGINES.

BY J. A. POWERS, C. E.

The able paper read at the late convention of the National Electric Light Association, at Pittsburgh, by Mr. Wm. Lee Church (see Electrical Engineer for March, 1888, p. 97), suggests some points in the relative coal economy of high and slow speed engines which it is believed are not fully nor fairly treated in that paper. That the experience of Mr. Church in the making, testing and using of high speed engines, leads him to the conclusion that the independent high speed engine is the best in average coal economy in incandescent light stations, because the stations which he cites as users of large engines are less economical of coal than other well designed stations using high speed engines is no proof that high speed is a better economist than slow speed, even for the variable loads of incandescent light stations. The great variety of boilers, settings and draft appliances, and in the quality of fuel in use render any comparisons of coal consumption valueless except as a general index of possible results. The only fair way to state the general problem is to make a distribution of the steam consumption, which would be about as follows:

First.—Steam loss by radiation, and used for boiler feed and in providing water supply, etc. This will constitute a certain nearly uniform amount per day for any given plant when under steam.



Mr. Church's Figure 2.

Second.—Steam consumed in engines, as shown by indicator cards.

It is this second item with which we are concerned, as the first will be an individual factor for each station.

We should then consider the nature of the loads imposed on the power plant in every electric light station, and then deal fairly with the problem. These loads are—

1st. Friction.—*a*, consists of friction of engines in use; *b*, friction of shafting in use; *c*, friction of dynamos and belting in use.

2d. Effective load; power required for conversion from mechanical to electrical energy, including the losses in conversion out-put.

It will be evident that the "friction" load in the case of independent engines will be a nearly uniform percentage of the electrical out-put at any time, providing each engine is loaded to about its fair capacity, while in the case of slow speed engines there will be a certain constant quantity introduced, viz., the friction of the engine shafting and dynamos necessary to be run whether without load or not when certain dynamos are in operation. This is a consequence of the inflexibility of the shafting system, and we must, therefore, under light loads pay a penalty of a larger percentage of friction to load, than with independent engines, and this will entail an extra coal expense. The question of the coal economy of the two systems, therefore, depends on whether the slow speed can save enough coal when under heavy load to more than counterbalance the losses by friction under light load.

It is not to be presumed that any sane man will design a station for such a loading as Mr. Church shows in his diagram No. 2, which is reproduced below, to be run by a single engine large enough to handle the entire load. No steam engineer would consider the idea of handling the lightest loads—say from 60 to 75 h. p.—with an engine of 400 horse capacity. The necessities of any but the smallest station call for a divided engine plant. If the question of reserve power be left out, a station of 400 horse might be properly provided with one engine of 100 horse and one of perhaps 300 horse, both slow speed if desired. If the smaller engine be a high speed the station will be on the same terms as a station with exclusively high speed engines during the hours of light loading, which would limit the question of relative coal economy to the hours of heavy loading, say from 4 till 11 P. M., and 5 to 8 A. M. The arrangement for such a plant should be to drive each engine to a section of shafting conveniently arranged to give each engine its separate shaft and dynamos. These sections may be coupled by a friction clutch when desired, and friction clutch pulleys should be used for the driven pulleys from the engines. The dynamos may be provided with loose pulleys on the shaft or with some kind of belt holder to enable the dynamo to be stopped without interfering with the line shaft. The dynamos may be belted in opposite directions in pairs when space will permit, so as to reduce friction to a minimum.

Now in comparing the relative friction of the two systems the friction of dynamos may be neglected, since any dynamo may be stopped as soon as its load is taken off, in either system; in one case by stopping an engine, in the other by shifting a belt. This brings the question of friction down to whether the friction of large engines and shafting exceeds that of small engines alone.

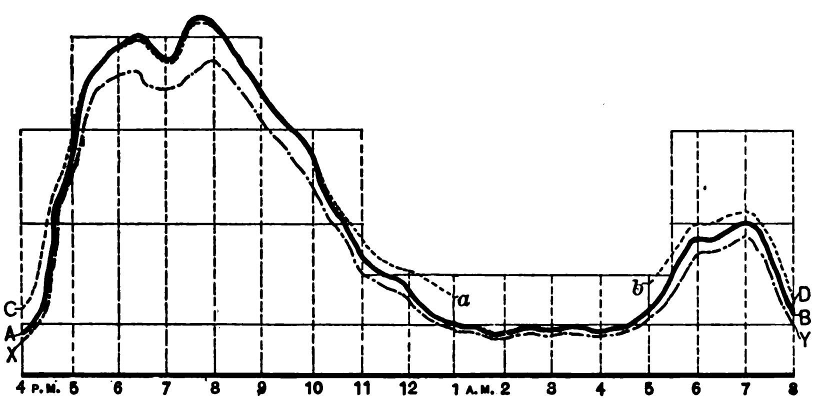
The friction of high speed engines is variously stated by engine builders at from five to eight or 10 per cent of full load. Probably the latter figure is not far from the truth, and if it were too large a percentage for full loading it must be remembered that a minute subdivision of power would be required to bring this about, and that this is neither practical in cost of investment nor of operation, and that a reasonably divided power plant will not ensure high speed engines always working on full loads. The percentage of friction will be greater under less than full loading, since engine friction seems to be nearly constant for all loading, in well designed engines.

Mr. Church states that shafting and engine friction ranges from 12 to 20 per cent. upward and not infrequently rises to 30 per cent. This may be possible, but it certainly is not so in all cases, and if we allow the same skill in designing a slow speed station which some of Mr. Church's show, it is entirely unnecessary. Indicator diagrams from a 20 x 48 Corliss engine driving 16 feet of $3\frac{7}{8}$ shafting at 320 revolutions, one 50-light Thomson-Houston 1,200 c. p. and one United States 20 arc light dynamo, out of circuit showed a total of $14\frac{6}{10}$ h. p., and deducting 3 h. p. for the dynamos, leaves $11\frac{6}{10}$ h. p. for friction of engine and line shaft, or $5\frac{8}{10}$ per cent. if the engine be rated at 200 h. p. This would indicate the engine friction to be as low as three per cent. The same engine driving 17 feet of $4\frac{7}{8}$, and 33 feet of $3\frac{7}{8}$ shafting with pulleys but

without belts, showed 22½ h. p. or nine per cent. for engine and shafting. If the dynamos are belted in pairs with belts pulling against each other, there will be no increase of their friction under load. A slight increase under load may be expected from the extra strain of the main engine belts under load, but a fair outside limit of 10 per cent. for engine and shafting friction may be taken from these data.

Now in the diagram shown of the load of an incandescent station (reproduced above) Mr. Church says that the heavy lines, A B, represent the fluctuation of the *actual load*, such as would be determined by indicating a series of independent engines, and the area enclosed between it and the base line, *mn*, may be denominated the net power required. This presumably includes the engine, belting, and dynamo friction of the high speed engine. Then Mr. Church proceeds to saddle all the sins of the high speed system on the slow speed system by saying: "The fine irregular line, *cd*, encloses the gross load when driven by a single large engine, being equaivalent to the *net load* plus the friction of the shafting and pulleys required in transmission." Thus assuming that the net load is the *indicated horse power* of the high speed engines, entirely ignoring the frictions which are chargeable to that system.

Now let us take some liberties with Mr. Church's diagram (see the figure below). We have reproduced his heavy line A B of gross loading as shown by the indicator on the high speed engine plant. From this line is constructed a new curve, shown in broken and dotted line, which is obtained by deducting from the ordinates to the curve A B, the 10 per cent of friction chargeable to the high speed system. This new line, X Y, is the true line of net power, and it is from this line that we must construct our friction curve for the slow speed system. This curve, C D will be found by laying off a line above the curve X Y, and distant from it 10 per cent of the maximum power in use. The diagram now shows simply the power used in driving the entire station, and does not consider the coal economy of the engines, which in Mr. Church's diagram is charged up against the slow speed system in the curve E F, and is not considered in the high speed curves at all. It will be noticed that this slow speed power curve, C D, nearly coincides with the gross power curve A B of the high speed system during the times of heavy loads, and that it rises above it as the load becomes less. The station is supposed to be operated by starting the 300 h. p. engine at 4 P. M. and supplementing it with the 100 h. p. at 5 P. M., then dropping off the 100 h. p. at 9 P. M. and starting it again at 11 P. M., shutting down the large engine at the same time. At 5.30 A. M. the 300 h. p. would be started and run till 8 P. M.; the 100 h. p. going out of service at 5.30 A. M.



We have now to consider the steam economy of the various types of engines in order that we may discuss intelligently the relative economy of the two systems. The following is a summary of the statement of engine builders on the point:

	Lbs. steam per h. p. hour.
High speed engines of 50 to 100 h. p.	28 to 32 lbs.
Corliss engines of 200 to 400 h. p.	
Single cylinder, high pressure	24 to 26 lbs.
" " condensing	20 to 21 lbs.
Compound, condensing	15 to 16 lbs.

These results would give with an evaporation of eight pounds of water per pound of coal,

	Coal per h. p. hour.
High speed	3.50 to 4.00 lbs.
Corliss single cylinder, high pressure	3.00 to 3.25 lbs.
" " " Condensing	2.50 to 2.62 lbs.
" Compound Condensing	1.87 to 2.00 lbs.

These results do not vary much from good practice for the Corliss engines, but the departure is very wide from the ordinary results in the case of the high speed type. A central station operator of great experience informed the writer not long since that he allowed six pounds of coal per arc lamp per hour as an average result. This would not be less than six to seven pounds of coal per horse-power hour for engines of 50 h. p. The experience of the writer goes to prove that this result is about correct for engines of that size. For 100 h. p. engines a result perhaps one pound better can be had. The results recently shown in changing some stations from high to slow speed seem to indicate the correctness of these results, one such case reporting a saving of 50 per cent. in fuel. Another case where a 20 x 48 Corliss was substituted for three 50 h. p. high speed the results were fully as good, though the Corliss engine was a part of the time under a very light load. The most curious result is that this engine is sometimes run under a load of 125 h. p. during a dark day in place of the 50 h. p. engine which ordinarily carries a day load of 60 h. p. and actually carries the heavier load with the same coal though the Corliss engine works at only half load, while the 50 h. p. was but slightly overloaded, and at a comparatively economical point of cut-off. This is a comparison of much value in considering the relative merits of the two systems, since the indications are that the Corliss engine is more economical even when under half loading than the 50 h. p. high speed engine is at a fair load.

Now let us consider the comparative coal consumption of the two systems on the power curves we have laid out in diagram No. 2. The planimeter shows between the base line and the power lines,

A B	h. p. hours 3,300	
C D		
4 to 11 P. M.		
11 P. M. to 5 A. M.		
5 A. M. to 8 A. M.		3,580

If these quantities are multiplied by the proper coal rates we have:

High speed A B, 3,300 × 5 lbs.		= 16.500
Slow speed C D.		
High pressure	3,300 × 3.25	— 10,750
Condensing	3,300 × 2.62	= 8,646
Compound condensing	3,300 × 2.00	= 6,600

These results show savings as follows:

	Saving.
High pressure Corliss	5,750 lbs.
Condensing "	7,854 "
Compound condensing	9,900 "

over the high speed engines at 5 lbs. coal per horse-power per hour.

Now the Corliss engine will not, of course, be working on an economical loading during part of the time, but in order to get an extreme comparison let us suppose that the Corliss system is run at full power whenever in use at all, or in other words, that the coal consumption is the same whether the engine is partly or fully loaded. I do not be-

lieve that the most ardent advocate of the high speed system will claim that a Corliss engine will burn *more* coal under light load than when fully loaded.

The schedule as above indicated would give the following horse-power hours:

310 h. p.,	4 to 11 P. M.	2,170
	5.30 to 8 A. M.	775
125 h. p.,	5 P. M. to 9 P. M.	500
	11 P. M. to 5.30 A. M.	812
		4,257

which would give the coal consumption—

High speed at 5 lbs coal per h. p. hour		— 16,500
Corliss, high pressure	4,257 × 3.25	— 14,835
" condensing	4,257 × 2.62	— 11,153
" comp. condensing	4,257 × 2.00	— 8,514

So that the high pressure Corliss engine is the better on coal consumption even under the *reductio ad absurdum*, that there is no saving in coal as the load becomes less, and giving the high speed engine the benefit of a coal rating at full load. It will be noticed also that the coal rates taken for Corliss engine, as above are the largest rates shown by ordinary practice and make no allowance for expert care which has its effect on all engines in saving of leakage and friction.

This discussion leads us to about the following conclusions as to the coal economy of the various types of engines, taking the high speed engine as unit:

	Coal consumption, lbs.	Percentage, saving.
High speed	16,000	0.00
Corliss, high pressure	11,000	.31$\frac{3}{10}$
" condensing	9,000	.43$\frac{3}{10}$
" comp. condensing	7,000	.57$\frac{3}{10}$

This is believed to be as fair a statement as can be shown from the average practice. These results speak for themselves. We must use condensing engines wherever possible, and to do this we must locate near a plentiful supply of water. If no stream or pond is convenient we must try driven or artesian wells. Both have proved effective, and location must determine the choice. The saving by condensing is not less than 25 per cent. under full loads, and one-quarter of our coal bill will pay large interest on any reasonable expenditure to obtain water supply.

First cost of steam plant is a matter of importance in station construction, and may be fairly stated about as follows for the different types of engine.

One 100 h. p. engine high speed	\$1,500 to \$1,800
" 200 " Corliss "	4,500 " 5,000
" " " " condensing	5,200 " 5,800
" 350 " " comp. condensing	13,000 " 14,000

If we add shafting to the cost of the last three engines we shall have a cost per horse-power—

	Cost per horse-power.
100 h. p. high speed engine	\$15 to \$18
200 " Corliss high pressure	30 " 32
200 " " condensing	33 " 36
350 " " comp. condensing	45 " 48

This is as far as the high speed advocate usually goes, but it is not far enough. If we need less steam we require less boiler capacity, and this reduction will be nearly in proportion to the coal rates of the different types of engines. A well set boiler of 60 inches diameter by 17 feet long with good draft will supply steam for three 50 h. p. engines, but will need forcing to do it. The same boiler will supply a 20 × 48 Corliss condensing engine of 250 h. p. much more easily.

We may fairly state the cost of steel boilers well set, as required by the different systems, about as follows:

100 h. p. high speed	\$16 to \$18 per h. p.
200 " Corliss	12 " 14 " "
200 " " condensing	10 " 12 " "
350 " " comp. condensing	7 " 9 " "

So that the total cost of steam plant will be about as follows:

High speed	\$31 to \$36 per h. p.
Corliss	42 " 46 " "
" condensing	43 " 48 " "
" comp. condensing	52 " 57 " "

Now let us compare our results of first cost and saving together,

	Cost per cent.	Coal consumption, per cent.
High speed	\$1.00	100
Corliss	1.31	62
" condensing	1.36	56
" comp. condensing	1.62	44

and with coal at \$3 per ton on the above schedule and interest at 6 per cent. the results will be for the 400 h. p. station under consideration—

	Cost of coal per day.	Saving in coal over high speed.	Interest per day on 400 h. p.	Loss in interest.
High speed	\$24.75	0.00	2.36	..
Corliss h. p	18.90	5.85	3.08	.72
" condensing	15.24	9.51	3.15	.79
" comp. condensing	11.64	13.11	3.75	1.39

Or in a 400 h. p. station the high pressure Corliss engine beats the high speed system \$5.13 per day, Corliss condensing \$8.72, Corliss compound condensing \$11.72.

It may be said that these figures are theoretical to some extent, but they will be found to agree pretty closely with the results of good practice for both systems.

It is to be noted that a number of stations lately laid out contemplate the use of Corliss engines, in part at least; and some of them from the plans of the best engineers we have.

The writer hopes to supplement this paper with a statement of some accurate tests on engines of each type, at an early date.

A STUDY OF CERTAIN ERRORS IN THE CONSTANT SHUNT METHOD.[1]

BY WILLIAM L. PUFFER, S. B.

A VERY neat and valuable application of Ohm's law is that usually called the shunt method for the determination of current. The method is described in the Munich, Vienna, and Philadelphia reports on dynamo tests as well as in the ELECTRICIAN AND ELECTRICAL ENGINEER, for January, 1885.

The principle is this: if a conductor of constant unknown resistance be placed in a circuit, and currents of different strength passed through it, there will be a difference of potential at the terminals of the conductor proportional to the currents flowing; and if this conductor be placed as a shunt upon a reflecting galvanometer whose resistance is high as compared to the conductor, and whose deflections are proportional to currents producing them, then the deflections will be proportional; first, to the currents in the galvanometer circuit; second, to the potential difference in the conductor; and third, to the currents in the conductor.

In order to extend the range of the apparatus, the galvanometer deflection can be kept the same by changing the total resistance in its circuit; then this total resistance is also proportional to the potential difference in the conductor. In order to save time, the galvanometer deflection may be nearly the same, and the product of the deflection and corresponding total resistance taken; these products will then be a measure of the corresponding currents in the conductor. If a known current be passed through this conductor or shunt, and the galvanometer deflection and total resistance of the galvanometer circuit multiplied, and the product divided by the known current expressed in am-

1. Read at a meeting of the American Academy of Arts and Sciences, January 11, 1888.

peres, we get the constant of the apparatus for amperes. To find value in amperes of an unknown current, we have only to note the deflection and total resistance in galvanometer circuit, multiply them, and divide by the constant. Or we could divide the known current by the product of resistance and deflection, and get a constant by which to multiply the resistance and deflection obtained with the unknown currents.

The range of the method is very great, and is, perhaps, limited only by the difficulty of making a suitable shunt of such a cross-section as to be free from injurious heating by the currents used.

Wishing to employ this method in the Rogers Laboratory of Physics in a slightly different way, requiring that the shunt resistance be known, I made some experiments to determine the resistance of a german-silver rod three feet long and 0.6 inch in diameter, with the intention of using it as a constant shunt of *known* resistance for currents from about 1 to 60 amperes. An inch from each end a small wire of german silver was silver soldered in a hole drilled nearly through the rod, and the lead wires running to a low resistance galvanometer were connected by screw-clamps. On the ends of the shunt were soldered brass screw connection for insertion of the main wires.

A standard ohm was placed in circuit with the shunt by means of mercury cups, and the resistance of the shunt found by comparison of the potential at its terminals with that at the terminals of the ohm, using a Hartmann dead-beat galvanometer and resistance box as usual with the shunt method.

The results were very unsatisfactory, although care had been taken to prevent, as far as possible, any error due to change in temperature, by placing both the shunt and the standard ohm in a water bath, and noting the temperature both before and after a set of readings.

As the observations were taken in a short time, and the resistances measured immediately afterward, it is not probable that there could have been any noticeable change during the experiment.

With the shunt in water, the results checked within about 0.3 per cent., the highest being 0.00 085 39, and the lowest 0.00 085 10 ohm. When the shunt was in melting ice the results were more variable, and in air very bad. A careful test of the wires and connection showed that when there was no battery in circuit, there was a variable electromotive force in both the galvanometer circuit, and in the shunt itself, sufficiently great to account for the errors in previous work.

The error in the galvanometer circuit was avoided by greater care in manipulation and the use of a mercury commutator; but the shunt proved so troublesome that a study of the nature of the small, disturbing electromotive force observed seemed desirable.

As this error, which I attributed to thermal action, was entirely negligible in the standard ohm because of the comparatively high difference of potential produced by the calibrating current, I thought that a german-silver shunt, capable of carrying 5 to 10 amperes, having a resistance of from 0.1 to 0.2 ohm, might be compared with the ohm, and then with the shunt, without any appreciable error from heating or thermal action.

The following is a brief description of the shunts made, and the arrangements for taking observations and avoiding errors :—

The large german-silver shunt has already been described. The standard german-silver shunt was made of a 50 foot length of wire of one-quarter inch diameter, drawn to order and of the quality known as "18 per cent." A short length of No. 14 german-silver wire was looped around this shunt near each end and silver-soldered to it, using borax as a flux, and similarly a set of copper wires as well, thus giving me virtually two shunts of the same resistance and material, differing only in the metal wires used for the potential leads. The shunt wire was doubled and bent back and forth through porcelain insulators fastened to a piece of board. Also a copper shunt was made of two pieces of No. 00 wire, each 11 feet long; these were connected by being soft-soldered into a brass block, using resin as a flux, and then coiled in the same directions, to avoid magnetic disturbance, and suspended from ebonite supports in a stone jar. At three places on this shunt—near each end and in the middle near the brass block—were soldered a set of four wires. Each set of four contained a german silver and a copper wire, silver-soldered with borax, and a similar pair soft-soldered with resin. This was equivalent to 12 simple copper shunts, with different leading wires and solders.

Each of these three shunts was placed in a tank of water provided with a thermometer. The potential wires were carried to mercury cups and commutators on a table 30 feet away, where the resistance boxes were placed.

The galvanometer was a double coil Hartmann, with bell magnet and copper damping-block; the deflections were read by a telescope and scale at a distance of 3.68 metres.

The galvanometer wires were soldered to amalgamated brass rods held in a piece of ebonite provided with a long handle, used in changing the connection from one set of wires to another.

In order to avoid temperature correction, the shunts were placed in water and carefully watched until it was evident there was no perceptible heating of the water or wires by the current. A loop of the galvanometer leads was always connected to a Wheatstone bridge used to measure the resistance in circuit. There was never any change large enough to cause any trouble, as the measurements were all taken in a short time, and the rise of temperature was very slow.

The deflections were always brought to about 10 double centimeters each side of the middle of the scale, and were written 1,000, calling the tenth of smallest division unity. Within the limits of the scale the proportionality of the deflections was nearly perfect, and quite so within the limits of working. The error due to change in length of the suspending fibre was studied, and found to be negligible only when the precaution was taken to compare a mark on the mirror with a mark on the metal frame of the instrument, and adjust the height of the mirror to 0.1 or 0.2 millimeter. The torsion of the fibre was negligible in the range of deflections used.

The galvanometer and its connecting wires had a resistance of 4.7 ohms, and was used as a voltmeter for measuring the thermal electromotive forces with an accuracy of about five per cent. The factor 0.00 000 040 was used to multiply the deflections by in order to obtain the thermal action in volts, when no resistance other than the galvanometer and connecting wires was in circuit.

It was assumed that these shunts would be calibrated with a current of one ampere, and that an accuracy of one part in 1,000 was desirable. The table gives the resistance of the shunts, and also the volts corresponding to an error of 0.1 per cent. of the difference of potential caused by a calibrating current of one ampere. These small electromotive forces are represented by two units of deflection of the voltmeter in the case of the copper and the large german-silver shunts, and 2,000 with the standard shunt.

	Resistance in ohms.	0.1% P. D., due to an ampere.
Large german-silver shunt..........	0.00 085	0.00 000 085
Standard german-silver shunt.......	0.16	0.00 016
Half of copper shunt	0.00 070	0.00 000 070

The large german-silver shunt in air often showed from one to three units deflection, sometimes in one direction and sometimes in the other; but when placed in water this error was reduced to a much smaller amount and seldom could be detected. At one time there seemed to be a vari-

able deflection, which was traced to the contacts in the screw connection used to join the galvanometer leads to the shunt wires; this was easily removed by bending the wires until the clamps were under water. After this I could never detect any deflection caused by thermal action in this shunt, although owing to the low resistance of the shunt an error of 0.05 per cent. would cause so small a deflection that it might pass unnoticed.

The copper shunt, with its different terminals, proved very interesting, and exhibited a great variety of thermal action which would, in many cases, be too large to be neglected if the shunt was to be used for comparison of currents.

The largest deflections were always found with the german-silver wires, and the least with copper wires with soft-soldered connection. The deflections were seldom twice alike even with the same wires, ranging from 0.0 to 20., being positive at one time and negative at others. The difference between the silver solder and the soft solder was not particularly marked, but seemed to be in favor of the soft solder, both with the copper and german-silver leads. These deflections were always smaller and more regular when the shunt was in water than in air. It often happened that the copper soft-soldered leads gave no indication of thermal action, and I never saw any indication of trouble from the double-soldered connection in the middle of the shunt.

This shunt was made to correspond approximately to some of the shunts described in articles on the shunt method of determining currents both in regard to size and length of wire and method of connecting the lead wires.

The thermal action in the standard german-silver shunt was very much greater than in any part or combination of the other shunts, being larger when the copper leads were used by about seven per cent.; still, even these large thermal E. M. F's were quite small when compared to that produced by the calibrating current, and could have been safely neglected if an accuracy of 0.1 per cent. was required. I thought I could now compare this shunt with the standard ohm easily enough; and then with the other shunts by using a current of several amperes, to get so great a difference of potential that the thermal effects would be drowned. I changed the storage battery letting the current pass through all three shunts, and after a few hours I broke the circuit, and tested the shunts to see whether the current had perceptibly heated them, although a sensitive thermometer showed no change. The copper and large german-silver shunts seemed about as usual, but the standard gave me a deflection of 2,000, which rapidly diminished. This was far too small to be of any effect with this particular shunt, but it was very suggestive. Examination of the shunt showed a slight blackening at the positive end and a few bubbles of gas, probably due to slight decomposition of water, as the difference of potential had been about 1.8 volts. A reversal of the current caused the blackening to appear at the other end of the shunt, and a slight lessening of the discoloration produced by the previous current.

A current of 22 amperes in all three shunts produced 3.5 volts in the standard, and in breaking, 0.00 06 volt at the end of half a minute, which fell to 0.00 000 2 at the end of five minutes. The deflection was in the same direction as when the current was passing, and was reversed by reversing the current. The other shunts gave no such effects even with 60 amperes, so work was chiefly on this shunt. A current of 45 amperes caused an effect which sent the spot off the scale for over a minute.

Curves were plotted, showing the diminution of the thermal effect at equal intervals of time after stopping the main current, which show that while the current is passing the apparent resistance of the shunt is greatly increased by this action. It appears as if this counter electromotive force increased with the current, although not quite in the same proportion.

At this point my experiments had to be postponed; so all apparatus was put aside for a number of months, and then set up in exactly the same manner and position, with the exception that I only used the standard german-silver shunt, to which I added three new sets of terminals,—two of german silver and one of copper, all soft-soldered, using acid for a flux.

Experiments were made to find what caused the variable deflection from this shunt after a current had been passing, and to see if there was any noticeable difference in the materials used in the potential leads and solderings.

I designated the different sets of leads in the following manner:—

Leads No.	1	were of	german silver,	soft-soldered.	
" "	2	"	copper,	"	"
" "	3	"	german silver,	"	"
" "	4	"	copper,	silver-soldered	
" "	5	"	german	"	"

When the shunt was in air, the effects—due to thermo-electric action arising from the slight differences in temperature in the shunt itself previous to the passage of a current,—were found to be of such a magnitude as to be negligible in a shunt of so high resistance as this one, although far too great to be permissible in a shunt of a resistance corresponding to those generally used. These thermal electromotive forces varied both in sign and amount from zero to 0.00 000 12 volt, and having as an extreme variation about 0.00 000 24 volt. In this respect the german-silver leads were anywhere from two to five or more times as bad as the copper, and the two soft soldered ones seemed to be best, although not enough so to make any marked difference in the readings, which were very small at most. The difference between the copper leads was not appreciable.

With the shunt in air I allowed various known currents to flow for five minutes, and then took several series of readings, every quarter or half minute for about five minutes or longer, if necessary, to see what effect was produced in the shunt by the passage of the current. When the currents were only two or three amperes there was no effect produced large enough to notice; and as I could readily detect an electromotive force greater than 0.00 000 04 volt the action, if any, must have been very small. With currents that produced a perceptible warming of the wire, I found a great variety of effects, differing even in the same set of leads at different times.

Curves were plotted, showing the effect produced by a current of 24.2 amperes in the shunt for five minutes. The sets of wires called No. 1 and No. 3 were made from the same piece of wire, and soldered at the same time with the same solder; and yet they vary in a very peculiar way, for which I have no explanation except that the composition of the german-silver shunt has been acted upon by the solder used, and that in the short length (about two inches near each end), where the soldered joints are, the metal is not homogeneous.

The greatest deflection shows the electromotive force to have been 0.00 002 volt. Both sets of copper wires act in a similar manner, and give curves which rise quickly during the first half minute, and then gradually drop. Terminals No. 5 give a curve which begins high and falls sharply, and recovers slightly only to fall again. The curves of No. 3 fall rapidly at first, then rise in a regular and very marked manner, after which a fall takes place. Terminals No. 1 do not give especially marked curves unless it be on account of the much smaller deflections than any of the other wires.

I next placed the shunt in water, and examined it the next morning before passing any current through it, and found a large deflection of 105 units, corresponding to 0.00 004 2 volt. There was a slight difference between the various leads, generally about 5 per cent, but all deflections were in the same direction. I was careful to see that all

parts of the shunt were under water, and that the soldered junctions were at nearly the same depth, but still the deflections remained. A current of 25 amperes was sent through the shunt to see if there would be a similar action to that when the shunt was in air, but upon connecting the galvanometer the deflection was entirely off the scale for five minutes, and lasted for an hour. I found that a current of less than an ampere in the shunt, but in the opposite direction, would reverse for a while the remains of the effect due to the 25 amperes. There was no apparent difference in the leads, and as the deflections were reversible by reversing the current, and always opposite to those produced directly by the current, I concluded that there was an electrolytic action caused by the current. The positive end of the shunt always turned black, and the negative end tended to become white. I found that by carefully timing duration and direction of currents, I could get a right deflection which would diminish and a left one begin, which would in turn give way to another right deflection, but I was not able to get four changes. With the soldered ends entirely out of water the actions were exactly the same; but the moment the *whole* shunt was out of water all action ceased, and the deflection became very small: even ten inches of submerged wire gave the deflection, though to a lesser degree, as did also a wet rag wrapped around the wire for a short length.

A current of less than an ampere would produce less than 0.2 volt at the terminals, yet I could get these effects by it, so that simple decomposition of the water was not the cause of the trouble, which it seems to me must be attributed to a "polarization" effect. Having found the cause of the strange deflections when the shunt was in water, I did not continue the experiments any longer. The reason the large german-silver shunt did not show such trouble is, probably, that it had been carefully shellaced when made, and was protected from the oxidizing action.

In the light of these experiments, it seemed desirable to plan a shunt and galvanometer for use in comparing currents ranging from 1 to 1000 amperes, which would not be affected by either thermal electromotive forces in its circuit or in the shunt itself. These data were assumed, and the galvanometer calculated.

Calibrating current to be 1 ampere.
Largest current to be 1000 amperes.
Resistance of shunt to be 0.001 ohm.
E. M. F. at terminals when calibrating 0.001 volt.
Largest observed thermal E. M. F. 0.00 000 8 volt.
Average observed thermal E. M. F. about 0.00 000 08 volt.
Galvanometer current when calibrating to be less than 0.001 ampere.
Galvanometer coils to be 25 ohms of german-silver wire.
Deflection to be 10 c. m. at 1.5 meters, or about 2°.
Earth's field alone to be used.
Required dimensions of galvanometer.

The field due to the coils must be 0.006 in order to produce a deflection of 2° where H is 0.1717. The current producing this field would be 0.00 000 4 absolute unit; 25 ohms of No. 18 B. & S. german-silver wire would be a length of 8,440 c. m.

$$\text{Then radius of coil} = \sqrt{\frac{8{,}440 \times 0.00\,000\,4}{0.006}} = 2.37 \text{ c. m.}$$

$$\text{Average length of a turn} = 2\,\pi\,r = 14.9 \text{ c. m.}$$

$$\text{Number of turns} = \frac{l}{14.9} = 566 \text{ or } 283 \text{ per spool.}$$

15 × 19 turns give a coil section 0.604 × 0.766 inch.

The galvanometer was made of a single copper casting, with two channels for the coils, 0.2 inch apart. Each channel was 0.77 inch deep, 0.61 inch wide, and had an inside diameter of an inch. If the galvanometer is much lower than 25. ohms, the variable plug resistance of an ordinary bridge will cause an error too great to be safely neglected when only the galvanometer, leads and plugs are in circuit. The reasons for the other numerical figures are almost self-evident.

The shunt itself I would make of thin sheet german silver, with either copper or german-silver end blocks, as was most convenient, but preferring copper. The lead wires to the galvanometer would be of copper, either soft or silver-soldered to the end blocks, and should go to a commutator very near the shunt itself, and the galvanometer circuit so arranged as to be easily disconnected from the shunt and placed in a mercury cup to close the circuit for the resistance measurement. I would prefer to measure the total resistance by a standard bridge always connected and kept at a constant temperature.

This kind of a shunt could easily be made so that there would be very little heating, and if shellaced, or protected from oxidation in any other manner, could be used in water, although some kind of oil would probably be better.

There should be suitable mercury cups arranged so that the current could be easily and quickly reversed in the shunt, or the shunt entirely disconnected from the circuit.

Rogers' Laboratory of Physics, January, 1888.

DISCUSSION OF THE PRECISION OF MEASUREMENTS.[1]

BY SILAS W. HOLMAN, S. B.

Assistant Professor of Physics, Massachusetts Institute of Technology.

(Continued from page 201.)

Best magnitudes. In using almost any instrument it will be found that, on account of the nature of its indications, its greatest accuracy is secured at a certain point or within a limited part of its range. In designing an instrument there will be a best proportion among its parts. In arranging the plan of an indirect measurement, there will be some magnitudes more favorable than others to be assigned to the various component measurements. Thus in general there will be best magnitudes, either actual or relative, of the components. For instance, current measurement by a tangent galvanometer, whose readings are taken from a circular scale of equal parts, is fractionally more precise at or about 45°;—a bar whose moment of inertia, I, is to be computed from its dimensions and weight, may have for a given value of I a best proportion between its length and diameter;—in the magnetometer there is a best ratio between the distances from the needle to the two positions of the deflecting magnet.

The problem therefore arises to determine what these best magnitudes are in any given case. This is but another and higher phase of the subject already presented. Instead of determining, as by "equal effects," the best values of the precision measures for given magnitudes of the components, we are now to determine the best magnitude of the component qualities for prescribed conditions in regard to the precision in their measurement, and to the relative or absolute magnitudes of the final result or one or more of the components.

These conditions are thus of two sorts, viz.: First, *Precision conditions, i. e.*, having given the absolute or relative precision measures δ_1, δ_2, etc. Second, *Magnitude conditions*; *i. e.*, having given the absolute values of the components M_1, M_2, etc., or of the final quantity and one or more of the components. To see more closely what this statement implies, consider that throughout all this subject, where we deal with the effect of errors of measurement, those quantities or components are treated as independent which are the subject of separate or independent measurement—not calculated from another. But quantities may properly be thus independently measured and treated which are not mathematically independent, but are "conditioned," so that one is capable of expression

1. Copyrighted, 1888, by S. W. Holman.—From *Technology Quarterly*.

in terms of another either with or without another independent quantity. The function expressing such a relation would then give an equation of condition which must be regarded in determining the "best magnitudes," though not needed in the simpler case of computing the precision of the result, or assigning the precision of components.

As examples of conditions let us take the following:—*a.* Required the best values of c, r, and t for measuring the electric energy, $W = c^2 r t$, expended in heating a conductor. Given as *precision conditions* $\delta c = 0.01$ ampere, $\delta r = 0.01$ ohm, $\delta t = 0.2$ sec.; *magnitude condition* $W = 5{,}000{,}000.$ units. Note that the quantities c, r, and t, are wholly independent except for the magnitude condition that W is fixed. The numerical solution is given subsequently under head of *solution of examples of best magnitudes.*

b. It is desired to construct to best advantage a right circular cylinder of brass, whose moment of inertia around a transverse central diameter is to be computed from $I = m\left(\frac{h^2}{12} + \frac{d^2}{16}\right)$ where $m =$ mass, $h =$ height or length of cylinder, $d =$ diameter of cylinder. The value of I is most easily determined by measuring directly m (by the balance), h and d, which would be treated as independent (independently observed) if we were discussing the precision of I. Now, in determining the best magnitudes of m, h, and d we must know first the precision conditions. Suppose the measurements show these to be,—δm negligible, $\delta h = \delta d =$ constant. Second, we must have the magnitude conditions,—which would vary with circumstances. Suppose that it is required that I shall be of a given amount. Then as δm is negligible, m may have any value consistent with the other requirements, and we have to find the best value of the ratio of h to d. But h, d, and m, although independently observed, are not mathematically independent; for $m = \frac{\rho \pi d^2 h}{4}$ where ρ is the density of the brass. Hence the magnitude conditions are $I =$ constant, and $m = \frac{\rho \pi d^2 h}{4}$. The algebraic solution is given subsequently.

Methods of solution of problems on best magnitudes may be reached in two principal ways. First, whatever the number of the components, provided that they are mathematically, as well as by observation, independent, we may show from the principle of least squares, as in deducing the formula XXI for "equal effects," that in the long run the best magnitudes of these components will be found by solving for them from either the general expression XXI or the proper special one from XXII to XXV. The solution will, of course, be made for values either absolute or relative of the components M_1, M_2, etc., under both the assigned precision conditions respecting δ_1, δ_2, etc., and the magnitude conditions. The method is intended for those cases involving three or more variables, and which cannot well be solved by the second method, about to be described. Its results are but approximate, and therefore will differ usually by a slight amount from those obtained by the second method, which is to be preferred for one or two variables. But it is to be remembered that a considerable departure from the best conditions will affect the precision but slightly, and that best values to 10 per cent. are usually more than sufficiently close.

Second, if the number of components is one or two, and if two, whether independent of each other or one a function of the other, we may solve more exactly by the usual process of finding minima by differentiation. (Todhunter's Differential Calculus, chapter on Maxima and Minima of Two Variables.) By this process the general plan of the solution would be this: Write by means of formulæ XIII to XX the expression for Δ or Δ^2 in terms of the δ's as given by the precision conditions. Simplify as much as possible, and find by differentiation the values of M_1, M_2, etc., which will make Δ a minimum.

The cases which arise in differentiating are as follows:—

1. Where $u = f(x)$, *i. e.*, where it is required to find the value of x which will make u a minimum, u being a function of x alone. Here, of course, the desired value of x will be formed from the familiar conditions.

$$\frac{du}{dx} = 0, \text{ and } \frac{d^2u}{dx^2} \text{ is } +. \qquad \text{XXIX.}$$

Inspection alone often suffices to solve this simple case.

2. Where $u = f(x, y)$, but x and y are *not* independent, but $y = \psi(x)$. In this, the most common case, the general solution is by the equation.

$$\left(\frac{du}{dx}\right) + \left(\frac{du}{dy}\right) . \ \psi'(x) = 0, \qquad \text{XXX.}$$

where the parentheses indicate that the differentiation with respect to the variable is made on the supposition that the other at the time remains constant; and where $\psi'(x)$ denotes $\frac{d\,\psi(x)}{d\,(x)}$. Of course there are further conditions to discriminate between maxima and minima, etc., which must be applied when inspection alone does not suffice. The expression XXX is solved for the best values of x, or of $x : y$, or of x and y, etc., as the case in hand may require.

It is often convenient, instead of employing XXX, to substitute directly for y its value $\psi(x)$, so that $u = f(x, \psi(x))$, and then to differentiate with respect to x and equate to zero, as in XXIX.

3. Where $u = f(x, y)$ but x and y *are* independent. In this case both conditions

$$\left(\frac{du}{dx}\right) = 0, \text{ and } \left(\frac{du}{dy}\right) = 0 \qquad \text{XXXI}$$

must be fulfilled. The parentheses indicate as in XXX. As before, the further conditions for minima have seldom to be considered, as inspection serves to discriminate in most cases.

Solution of examples of best magnitudes. 1. Problem previously stated at *a.* $W = c^2 r t = 5{,}000{,}000.$ Precision conditions: $\delta c = 0.01$ ampere, $\delta r = 0.01$ ohm, $\delta t = 0.2$ second. Magnitude condition: $W = 5{,}000{,}000.$

To find magnitudes of c, r, and t to make ΔW a minimum. Solving by equal effects (general expression XXI.)

$$\frac{dW}{dc}\ \delta c = \frac{dW}{dr}\ \delta r = \frac{dW}{dt} . \ \delta t$$

$$\frac{dW}{dc} = 2\,c\,r\,t, \quad \frac{dW}{dr} = c^2\,t, \quad \frac{dW}{dt} = c^2\,r.$$

$$\therefore\ 2\,c\,r\,t \times 0.01 = c^2\,t \times 0.01 = c^2\,r \times 0.2$$

$$\therefore\ r = \frac{c}{2} \text{ and } t = 10\,c$$

Substituting these gives

$$W = 5{,}000{,}000. = c^2 \times \frac{c}{2} \times 10\,c = 5\,c^4$$

$\therefore c = 32$ amperes, $r = 16$ ohms, and $t = 320$ seconds are the desired best magnitudes.

Or by the formulæ for factors (XXIV),

$$\left(\frac{\delta c^2}{c^2} = \frac{2\,\delta c}{c}\right) = \frac{\delta r}{r} = \frac{\delta t}{t} \therefore \frac{2 \times 0.01}{c} = \frac{0.01}{r} = \frac{0.2}{t},$$

$$\therefore r = \frac{c}{2}, \text{ and } t = 10c. \ \therefore W = 5\,000\,000 = c^2 \frac{c}{2} \times 10\,c = 5c^4$$

$\therefore c = 32$ amperes, $r = 16$ ohms, $t = 320$ seconds, as before.

2. Suppose a tangent galvanometer read by an index moving over a circle graduated to equal parts. The precision measure, $\delta\,\varphi$, of deflection readings will be the same at all parts of the scale. Let φ be any reading, and K the galvanometer factor, the current is given by $C = K \tan\varphi$. Required the value of φ at which the errors of reading will have least effect, *i. e.*, for which $\frac{\varDelta C}{C}$ will be a minimum.

Precision condition : $\delta\,\varphi =$ constant.

Magnitude condition : none,

By xv.

$$\frac{\varDelta C}{\varDelta \varphi} = K \frac{d \tan \varphi}{d \varphi} = K \sec^2 \varphi, \quad \therefore \frac{\varDelta C}{C} \frac{2 \varDelta \varphi}{\sin 2\varphi} \qquad \text{XXXII.}$$

By XXIX the value of φ, which will make $\frac{\varDelta C}{C}$ a minimum, is to be obtained from

$$\frac{d}{d\varphi}\left(\frac{\varDelta C}{C}\right) = o \;\therefore\; \frac{d}{d\varphi}\left(\frac{1}{\sin 2\varphi}\right) = \frac{d}{d\varphi}\left(\operatorname{cosec} 2\varphi\right)$$

$$= -\frac{\cos 2\varphi}{\sin^2 2\varphi} = o.$$

Hence— $\frac{\cos 2\varphi}{\sin^2 2\varphi} = 0$, $\therefore -\cos 2\varphi = 0$, and $\varphi - 45°$, as, indeed, might have been seen at once from inspection of XXXII.

3. It is desired to construct a circular brass cylinder of given mass, m, whose moment of inertia around a central transverse diameter may be determined by measurements of its mass and dimensions with as great accuracy in units as possible. $I = m\left(\frac{h^2}{12} + \frac{d^2}{16}\right)$, where $h =$ height or length and $d =$ diameter.

Precision conditions : $\delta\, m$ negligible, $\delta\, h = \delta\, d =$ constant. Magnitude conditions : $m =$ constant, and $m = \frac{\rho \pi d^2 h}{4}$ where $\rho =$ density of brass = a constant.

From XIII. we find

$$\varDelta^2 I = \frac{m^2 h^2}{36} \cdot \delta^2 h + \frac{m^2 d^2}{64} \cdot \delta^2 d \text{ or as } \delta h = \delta d$$

$$\varDelta^2 I = \frac{m^2}{4}\left(\frac{h^2}{9} + \frac{d^2}{16}\right) . \;\delta^2 h$$

We have now to find the value of $\frac{h}{d}$, which will made $\varDelta I$ a minimum. Now $\varDelta I$ is a minimum when $\varDelta^2 I$ is so, and therefore (rejecting constant factors) when $\frac{h^2}{9} + \frac{d^2}{16}$ is so. Now h and d are not mathematically independent, because m is fixed, but from above value of m, $d^2 = \frac{4\,m}{\rho \pi h}$.

The case, therefore, falls under XXX, and we have

$$u = \frac{h^2}{9} + \frac{d^2}{16}, \; x = h, y = d, y = \psi(x) = \sqrt{\frac{4\,m}{\rho \pi h}}$$

$$\left(\frac{du}{dx}\right) = \frac{2h}{9}, \; \left(\frac{du}{dy}\right) = \frac{d}{8}, \; \psi'(x) = -\frac{d}{2h}$$

$$\therefore \frac{2h}{9} - \frac{d^2}{16h} = o \;\therefore \frac{h^2}{d^2} = \frac{9}{32}, \text{ and } \frac{h}{d} = \pm 0.53$$

Or we may solve by the second way previously suggested, as follows :

$d^2 = \frac{4\,m}{\rho \pi h}$ $\therefore$ substituting this in $\frac{h^2}{9} + \frac{d^2}{16}$ we have $\frac{h^2}{9} + \frac{4\,m}{16 \rho \pi h}$ to be made a minimum. Solved by XXIX.

$$\frac{d}{dh}\left(\frac{h^2}{9} + \frac{4\,m}{16 \rho \pi h}\right) = \frac{2h}{9} - \frac{4\,m}{16 \rho \pi h^2} = o$$

Restoring now for $\frac{4\,m}{\rho \pi h}$ its equivalent d^2, we have

$\frac{2h}{9} - \frac{d^2}{16h} = o$, whence as before $\frac{h}{n} = \pm 0.53$.

4. Problem previously stated at b.

Precision conditions : $\delta\, m$ negligible, $\delta\, h = \delta\, d =$ constant.

Magnitude conditions : $I =$ constant, $m = \frac{\rho \pi d^2 h}{4}$, ρ = constant.

The problem is similar to 3, but the value of I is now determined in advance instead of m, and it is desired to construct the bar so that I may be found with as great fractional accuracy as possible, which as I is fixed will be when $\varDelta I$ is a minimum. We will solve first by finding the minimum by differentiation.

The value of $\varDelta^2 I$ is as in 3, but m is now not fixed, so that h and d are independent of each other. We have not to adjust the magnitude of m, because whatever this may come out, $\delta\, m$ is negligible. But m is a function of h and d and ρ, and as it is not constant we must substitute for it the value $\frac{\rho \pi d^2 h}{4}$ before differentiating with respect to h and d, in order to fulfill the magnitude condition respecting I and ρ. We have now to find the value of $\frac{h}{d}$, which will make $\varDelta I$, and hence $\varDelta^2 I$, a minimum. Hence, substituting for m and removing constant factors $\frac{d^4 h^4}{9} + \frac{d^6 h^2}{16}$ must be a minimum.

This case, as h and d are independent, falls under XXXI, and

$$\frac{du}{dh} = \frac{4 d^4 h^3}{9} + \frac{d^6 h}{8} = o, \text{ and } \frac{du}{dd} = \frac{4 d^3 h^4}{9} + \frac{3 d^5 h^2}{8} = o.$$

Equating these, dividing by d^7 and transposing, gives

$$\frac{h^3}{d^3} - \frac{h^2}{d^2} + \frac{27}{32} \cdot \frac{h}{d} - \frac{9}{32} = o$$

This by approximate solution yields $\frac{h}{d} = 0.47$ as the desired ratio. [Methods for approximate solution of such equations may be found in some works on algebra ; *e. g.*, Wells' University Algebra, page 417.]

This fourth problem may also be solved, of course, by the condition of equal effects, but, as already stated, the result may not be precisely the same as the more exact one just obtained.

$$I = m\left(\frac{h^2}{12} + \frac{d^2}{16}\right) = \frac{\rho \pi d^2 h^3}{48} + \frac{\rho \pi d^4 h}{64}$$

As $\delta\, m$ is negligible and ρ is constant,

$$\frac{dI}{dh} \cdot \delta h = \frac{dI}{dd} \cdot \delta d, \text{ and as } \delta h = \delta d, \; \frac{dI}{dh} = \frac{dI}{dd} .$$

$$\frac{dI}{dh} \frac{\rho \pi d^2 h^2}{16} + \frac{\rho \pi d^4}{64}, \text{ and } \frac{dI}{dd} = \frac{\rho \pi d h^3}{24} + \frac{\rho \pi d^3 h}{16}$$

Equating and transposing gives

$$\frac{h^3}{d^3} - \frac{3\,h^2}{2\,d^2} + \frac{3\,h}{2\,d} - \frac{3}{8} = 0$$

This, by approximate solution, yields $\frac{h}{d} = \frac{1}{2}$ approx. as the desired ratio. This solution by equal effects is not intended, as has elsewhere been stated, for application where the ordinary differentiation will apply, but for cases with three or more variables.

Investigation of special problems. As further illustrations of the application of the foregoing methods, and to illustrate the way in which any considerable investigation presents for solution its own special line of problems, the following discussions are given.

Cradle dynamometer. The principle and operation of the Brackett cradle dynamometer are known to electricians. The cradle consists of a platform suspended at each end from a horizontal knife-edge, both having their edges in the same line. If the rate at which mechanical work is put into a dynamo is to be measured, the dynamo is placed upon the platform with its axis of rotation as nearly as possible in the line of the knife-edges. The centre of gravity of the whole system is brought up close to the same line by means of counterpoise weights above the edges. The rotatory moment applied to the machine is counterbalanced by a known weight, w, applied at a known distance, l, along a horizontal arm rigidly attached to the cradle; and the number, n, of rotations per minute of the dynamo shaft is counted. We have thus to measure three quantities, w, l and n. But a study of the reliability of the cradle dynamometer involves more than the consideration of the exactness with which the quantities w, l and n can be observed. The general action of the instrument must be considered to see whether there are in its adjustment or action, during or before a run, any causes which might tend to produce errors, whose existence might perhaps not be indicated by the action of the apparatus at the time. A discovery of such would lead to their study with a view to finding the conditions governing the design or use of the dynamometer.

It is, of course, impossible to maintain the dynamometer absolutely at its normal position at all times during measurement; *i. e.*, to keep its pointer at the zero or fiducial mark. It is therefore essential that the centre of gravity of the whole system should be sufficiently near the line of the knife-edges, so that the failure to adjust to zero during a run shall produce a sufficiently small effect; that is, it is necessary that the system, like a balance in weighing, shall have a sufficient sensitiveness. If the axis of the dynamo shaft were adjusted as nearly as possible to the line of the knife-edges, with the belt off, still on putting the belt on for a run, there would be introduced by the belt-pull a moment of rotation about that line, because the adjustment could not be absolute. We must therefore find whether by making the zero adjustment with the belt on, thus counterpoising this erroneous moment in large part, we may sufficiently eliminate its effect. Then there arises the very important question as to the rigidity essential in the whole system. Under the belt-pull the shaft axis and the centre of gravity of the whole system must be somewhat displaced. How small must this be in order to be of no sensible effect; that is, how rigid must the system be in order that the erroneous moment introduced either by the belt-pull acting through the displaced axis, or by the great weight of the whole system acting through its displaced centre of gravity, may be negligible or of the same effect as the other unavoidable sources of error. These and some other points will be now developed. In order, however, to make the problem cover a fairly illustrative case of use of the dynamometer, it will be stated as follows:—

Desired to one part in 100 the efficiency of conversion, E, of a 60 incandescent light shunt dynamo, the measurements of power to be made by the cradle dynamometer. Given in advance the rough values:—current $= c = 60$. amp.; volts at terminals of dynamo $= v = 75$. volts; resistance of armature $= r_a = 0.003$ ohms; resistance of field coils $r_f = 20$. ohms; number of rotations of armature per minute $= n = 1400$.; length of fixed arm for weights $= l = 3.4$ ft.; diameter of dynamo pulley $= 2R = 10$ inches; weight of dynamo + dynamometer $= P = 3{,}000$ lbs.; efficiency of conversion $= E =$ about 90 per cent. Required the closeness necessary in the component measurements and in the adjustments, and a study of the rigidity necessary in the whole system. How far should π be carried in the computation, and how closely should the factor (746) for reduction of volts to horse-power be computed?

Let L denote the total rate of electrical output in horse-power, and W the rate of application of mechanical power.

Then $E = \frac{L}{W} = 0.9$. For shunt machine,

$$L = \left(c\,v + c^2\,r_a + \left(\frac{v}{r_f}\right)^2 r_f\right)\frac{1}{746} = 6.4 \text{ h. p. approx.}$$

In the parenthesis $c^2\,r_a$ is written for $c^2_a\,r_a$, as being a sufficiently close approximation.

Whence $W = 7.1$ h. p. approx. And as $W = \frac{2\,\pi\,l\,n\,w}{33000.}$, we find $w = 8$ pounds.

It will be convenient if we can separate mechanical from electrical quantities in the discussion. This we may accomplish by assigning proper relative precision[1] to the factors L and W, and treating each by itself. Since each of these contain about the same number of observed quantities as the other, it will be sufficiently close to write

$$\frac{\Delta\,W}{W} = \frac{\Delta\,L}{L} = \frac{1}{\sqrt{2}}.\ \frac{\Delta\,E}{E} = \frac{0.01}{\sqrt{2}} = 0.007$$

Electrical—By general method. *N. B.*—In differentiating with respect to c, the term $c^2\,r_a$ may be dropped, since it is only $\frac{1}{460}$th of cv; and in differentiating with respect to v, the term $\frac{v^2}{r_f}$ may similarly be dropped.

$$\frac{d\,L}{d\,c} = \frac{v}{746} = 0.10;\ \frac{d\,L}{d\,r_a} = \frac{c^2}{746} = 5.;\ \frac{d\,L}{d\,v} = \frac{c}{746}$$

$$= 0.09;\ \frac{d\,L}{d\,r} = -\frac{v^2}{746\,r^2} = -0.02.\quad \Delta\,L = 0.007$$

$$\times\ 6.4 = 0.045;\ \frac{\Delta\,L}{\sqrt{3}} = 0.027,$$

using $n = 3$ because r_a may be neglected, as inspection will show.

$\delta\,c = 0.027 \div 0.10 = 0.27$ ampere, $\delta\,r_a = 0.027 \div 5 = 0.005$ ohms.

---

1. Suppose $M = f\,(M_1,\ M_2, \ldots,\ M_r,\ M_s, \ldots,\ M_t)$ when all M's are observed quantities, and that $f\,(\,)$ is capable of separation into two (or more) factors each a function of observed quantities, so that

$$M = f\,(M_1, \ldots,\ M_t) = \varphi\,(M_1, \ldots,\ M_r).\ \rho\,(M_s \ldots,\ M_t).$$

Let r and p denote the number of quantities in $\varphi\,(\,)$ and $\rho\,(\,)$, respectively. Then for equal effects

$$\frac{\Delta\,\varphi\,(\,)}{\varphi\,(\,)} = \sqrt{\frac{r}{n}}.\ \frac{\Delta\ M}{M} \text{ and } \frac{\Delta\,\rho\,(\,)}{\rho\,(\,)} = \sqrt{\frac{p}{n}}.\ \frac{\Delta\ M}{M}$$

where $\frac{\Delta\,\varphi\,(\,)}{\varphi\,(\,)}$ and $\frac{\Delta\,\rho\,(\,)}{\rho\,(\,)}$ are the fractional precision of $\varphi\,(\,)$ and $\rho\,(\,)$, respectively.

$\delta v = 0.027 + 0.09 = 0.3$ volt, $\delta r' = 0.027 \div 0.02 = 1.4$ ohms.
Hence r_e may be neglected altogether, and r_f must be measured with coils at temperature attained during the run.

Also, $\frac{\Delta 746}{746} < \frac{1}{10} \cdot \frac{\delta L}{L} < 0.0007 \therefore \Delta 746 < 0.5$.

Mechanical.—By factors. $\frac{\delta l}{l} = \frac{\delta n}{n} = \frac{\delta w}{w} = \frac{1}{\sqrt{3}} \frac{\Delta W}{W} = 0.004.$

$\delta l = 0.004 \times 3.4 = 0.014$ ft. $= 0.17$ inch.
$\delta n = 0.004 \times 1400 = 5.6$ rota. p. m.
$\delta w = 0.004 \times 8 = 0.03$ lbs. $= 0.5$ oz.

$\frac{\delta \pi}{\pi} < \frac{1}{10} \cdot \frac{\delta w}{w} < 0.0004$, $\delta \pi < 0.0012 \therefore \pi = 3.142$ is sufficient.

Sensitiveness and index error.—The sensitiveness o the whole system to turn about the knife-edges is measured by the weight p (to be found by trial) necessary, when suspended at the distance l along the lever arm, to move the index from zero to one division of its scale. Suppose $n =$ average number of divisions unavoidable error in adjusting to zero or normal position during run. Then $\frac{n p}{w}$ is the fractional error in total weight w at l due to this source. To be negligible this must be less than $\frac{1}{10} . \frac{\delta w}{w}$ $\therefore p < \frac{1}{10} \cdot \frac{\delta w}{w} . \frac{w}{n}$. For the case in hand $w = 8$ lbs., and suppose $n = 0.25$ division (m. m.), and $\frac{\delta w}{w} = 0.004$, $\therefore$ $p = 0.0004 \times \frac{8}{0.25} = 0.013$ lbs. $= 0.2$ oz. This limit may be easily reached. Ten times this amount would cause an error of the same magnitude as $\frac{\delta w}{w}$.

Shaft to line of knife-edges, and zero adjustment.—How closely must this adjustment be made with the belt off? Let $2a =$ sum of tensions on two sides of belt. Assume for simplicity, at present, a parallel belt. Whether the belt is at rest or running the resultant pull is about the same in amount and direction; and as at time of weighing there is rotation without translation, there must be a resultant through axis of shaft equal to $2a$, and in same direction. If this axis is out of line of knife-edges by a perpendicular distance, d, there is on the dynamometer a moment not exerted in rotating the armature but still to be counterbalanced at l; *i. e.*, an erroneous moment, of amount $2ad \sin \theta$, where θ is the angle between direction of resultant belt-pull and direction of d, an angle equally likely to have any value. Let $R =$ radius of pulley on dynamo, $b = T - S =$ excess of tension of tight over slack side of belt. Then $bR =$ driving moment. Hence fractional error from imperfect adjustment, *i. e.*, ratio of erroneous to driving moment, is

$$\frac{a\, a\, d \sin \theta}{b\, R}$$

for which we must find a in terms of b. For leather belt on iron pulley $T + S$ cannot be more than about $\frac{5}{3}$ without excessive slip; and on tight dynamo belts it is likely to be much more than this. Hence

$$\frac{T}{S} = \frac{a + \frac{b}{2}}{a - \frac{b}{2}} = \frac{5}{3} \therefore a = 2\, b$$

as a least value, and $a = 5b$ would be nearer an average amount. Substituting the latter *under the assumption* that it is *constant*, *i. e.*, that the resultant belt-pull remains constant, gives

$$\frac{2\, a\, d \sin \theta}{b\, R} = 10 \frac{d}{R} \sin \theta$$

This, then, would be the fractional error if shaft were aligned with knife-edges, and dynamometer were brought to zero position with belt off, and *not* again adjusted with belt on, which would be the easiest, but, as will be seen, a very inexact procedure. In order that this error may become negligible,

$$10 \frac{d}{R} \sin \theta < \frac{1}{10} \cdot \frac{\delta w}{w} \therefore d < \frac{1}{10} \cdot \frac{\delta w}{w} \frac{R}{10 \sin \theta}.$$

Of course θ is always unknown. We may, therefore, solve for its average value $\frac{2}{\pi}$ or $\frac{2}{3}$ approx. In the present case $R = 5$ inches, whence $d = 0.0004 \times \frac{5}{10 \times \frac{2}{3}}$ 0.0003 inch, in order to be negligible, or 0.003 inch to be of same effect as $\frac{w}{w}$. Obviously either of these limits is utterly beyond reach, and hence the dynamometer *must* be adjusted to zero or normal position *with belt on and strained* to full tension at which it is to be run. If this were done the error would be fully compensated, *provided* that the belt-pull remained constant and the index were kept at zero at all times, and, also, that d remained constant,—a point to be considered later. But all of these provisions are impossible of fulfillment, and must, therefore, be further discussed. First, then, as index cannot be returned to zero at time of weighing within n divisions ($n = 0.25$ as already stated for this case), we must find how small d must be in order that this unavoidable error may be negligible. Moving index over n divisions will turn dynamometer through a small angle $\delta \theta$, such that $\delta \theta = \tan^{-1} \frac{n}{l}$. Now the change in erroneous fractional moment due to this will be

$$\frac{d}{d\theta}\left(10 \frac{d}{R} \sin \theta\right) = -10 \frac{d}{R} \cos \theta \therefore \delta \left(10 \frac{d}{R} \sin \theta\right) = -10 \frac{d}{R} \cos \theta . \delta \theta.$$

To be negligible this must be less than $\frac{1}{10} \frac{\delta w}{w} \therefore d < \frac{1}{10} \cdot \frac{\delta w}{w} \frac{R}{10 \cos \theta . \delta \theta}$.

For the case, in hand $n = 0.25$ mm., and $l = 3.4$ ft. $= 1040$ mm.

$$\therefore \delta \theta = \tan \theta = \frac{n}{l} = \frac{0.25}{1040.} = 0.00025,$$

and to be of negligible effect for average value, $\frac{2}{\pi}$, of $\cos \theta$

$$d < 0.0004 \frac{5.}{10 \times \frac{2}{3} \times 0.00025} = 1.2 \text{ inch.}$$

Thus so far as error from erroneous moment of belt-pull owing to imperfect zero adjustment is concerned, a very rough adjustment to line of knife-edges will suffice.

But the assumption that the belt-pull is the same when the belt is running as when stationary, and that it remains constant during a run,—apart from fluctuating changes which neutralize each other,—is one which persons familiar with leather belts in practice will not readily grant. Even under favorable conditions, the quantity $2a$, when the belt is running is liable to differ by several per cent. from its value when the belt is stationary. Hence we must see how this affects the admissible value of d. Let us compute the value of d, which would lead to a negligible error for a ten per cent. change in the total belt-pull. Obviously this would be ten times as great as the value found in the solution for the error due to the total belt-pull; *i. e.*, it would be

$$d' = 10 \times 0.0003 \text{ inch} = 0.003 \text{ inch},$$

or to be of same effect as $\frac{w}{w}$, $d' = 0.03$ inch. There are no sufficient data to determine whether a change of ten per cent. is unusual; but in my opinion it is not so. Any permanent change in belt-pull would be indicated by changed position of rest after the run. Thus the alignment of axis to knife-edges must be made with very great care, in order that the unavoidable errors may not be greater than those coming from δw, δw, etc., and it can hardly be rendered much smaller than these.

From the considerations of this section we then infer that

Dynamo shaft must be adjusted as nearly as possible to line of knife-edges.

Dynamometer *must* be adjusted to zero with belt on and tightened.

Belt should not be unduly tight.

Radius of dynamo pulley should be as large as possible.

Yielding of structure under belt-pull. Erroneous belt-pull.—The system of structure consisting of the dynamometer and the attached dynamo cannot be absolutely rigid. The belt-pull is large (200 to 500 lbs., say, in present case). Under this stress the structure is strained, and the shaft is thus displaced from the line of the knife-edges. Also, as the shaft is not an absolute fit in its journals, it may "climb" slightly in running, with an effect similar to the above. We have first to consider the erroneous moment due to the belt-pull, arising from this yielding. This problem is similar to the one solved in the last section. Let d be the amount of displacement of axis, measured at the pulley and normally to the line of the knife-edges. That part of d which is constant will be compensated by the adjustment to zero with the belt on. That part which is rapidly fluctuating will eliminate itself; and the component of d in the direction of the belt-pull will not be effective. Only the progressive change in d will enter into the result. To study the effect of this we have to differentiate the expression for the fractional erroneous moment with respect to d.

$$\frac{d}{d\,d}\left(10 \frac{d}{R} \sin \Theta\right) = \frac{10}{R} \sin \Theta.$$

Of course the tendency to greatest yielding will be in the direction of the belt-pull. But owing to the form of the structure, the direction of d will usually be more or less out of that line. The value of Θ would have no general average. Let us solve for $\Theta = 90°$. Then for case in hand, to be negligible,

$$\delta d < \tfrac{1}{10} \cdot \frac{\delta w}{w} \cdot \frac{R}{10 \sin 90°} < 0.00\,02 \text{ inch},$$

or 0.002 inch to be of same effect as $\frac{\delta w}{w}$. This shows the vital importance of great rigidity, and leads us to inquire in what direction the yielding will probably be least. A consideration of the form of the system shows that this will be the vertical direction. Hence the belt should be run vertically, and, preferably, downward. Thus

Whole system must be very rigid.

Belt should run downward from dynamo pulley.

Dynamo must be adjusted to zero, with belt on and tightened.

Yielding. Displacement of centre of gravity.—Let h be the horizontal and v the vertical component (referred to the dynamometer in its normal position) of the displacement D of the centre of gravity of the whole system under the belt-pull (or for any cause), D being measured perpendicularly to the line of the knife-edges. Let P represent the weight of the whole apparatus. The vertical displacement produces no effect except to slightly change the sensitiveness. The fractional error in the measured moment would be $\frac{P\,h}{w\,l}$, which obviously diminishes as the weight of the whole is less and as the value of $w\,l$ increases, *i, e.*, as the rate of output is larger. If the dynamometer is adjusted to zero with the belt on, then the constant part of this error is eliminated, and the error is reduced to $\frac{P.\delta h}{w\,l}$ when δh represents the permanent or progressive change in h, since fluctuating changes eliminate themselves. To be negligible,

$$\delta h < \tfrac{1}{10} . \frac{\delta w}{w} . \frac{w\,l}{P}$$

In the present case this gives

$$\delta h < 0.0004 \times \frac{8 \times 3.4}{3{,}000} = 0.00\,000\,4 \text{ ft.} = 0.00\,005 \text{ inch},$$

or 0.0005 inch in order to be of same effect as $\frac{\delta w}{w}$. Obviously this would require enormous rigidity of construction and attachment with a belt running in any other direction than that (downward) of greatest resistance, and very great resistance in that case. Hence,

Very great rigidity of construction and attachment in every part is essential in accurate work with a cradle dynamometer.

Belt should run vertically downard from dynamo pulley.

The greater the output and the smaller the weight of the apparatus, the better the result.

It would obviously be of decided advantage to drive the dynamo by means of a *couple without thrust* upon the axis if possible.

Position of centre of gravity.—To find experimentally the distance x of the centre of gravity below the knife-edges: Use letters with former significance, then $p =$ weight at l necessary to tip system through such small angle φ that the index moves over one division of the scale. Then

$$P x \tan \varphi = p\,l,\ \tan \varphi = \frac{1}{l} \therefore x = \frac{p\,l^2}{P}$$

For case in hand, suppose p to have been found by trial as 0.1 oz. = 0.06 lbs., when system was in adjustment. Then

$$x = \frac{0.06 \times 1040.^2}{3000.} = 22. \text{ mm.}$$

Tangent galvanometer. It is of importance to know the closeness necessary in the component measurements, in

the corrections, in the adjustments, etc., necessary in the tangent galvanometer of the form ordinarily employed in the laboratory. The following discussion affords not only this knowledge, but a basis for computing the dimensions of such an instrument for any desired work. The galvanometer here discussed is of a type having a single coil of n turns; radius $r = 20$ cm., about; breadth $= 2b = 2$ cm., about; depth $= 2d = 2.4$ cm., about; needle, with distance between poles, $= 2l = 1$ cm., about, suspended by single silk fibre (coeff. torsion $= \Theta$), and carrying glass index read to 0°.1 by estimation on circle of about 10 cm. diameter, parallax error being reduced by use of mirror. The expression for the current is, in its simple form,

$$C = \frac{10\,H r}{2\,\pi\,n}.\tan\varphi.$$

But the second member requires several corrections and assumes several adjustments to be properly made. The corrections may be introduced in the form of factors, so that the whole may most readily be treated by the method of factors. These factors will be indicated as we go on, and will be denoted by m_1, m_2, etc. The solution will be made to find the closeness necessary in the components, adjustments, etc., to produce *separately*

$\frac{\delta\,C}{C} = 0.001$. The attainable closeness will also be considered.

$m_1 = \frac{10}{2\,\pi}$ is a numerical factor which should, of course, be taken to $\frac{\delta\,m_1}{m_1} < \frac{1}{10} \times 0.001$ whence π should be taken to 3.1416.

$m_2 = H = 0.17$ abt. $\therefore \frac{\delta\,H}{H} = 0.001 \therefore \delta\,H = 0.002$ abt.

The measurement of H with this precision is difficult; and diurnal and local variations are of about this order of magnitude, though the latter may be much larger. The nature and magnitude of the errors entering into the measurement of H depend so entirely upon the method and instrument employed that they will not be here discussed. It will be assumed that H can be found to less than

$\frac{\delta\,H}{H} = 0.003$. It should be remembered that *relative* measurements of C are independent of the absolute value of H, and are subject only to the variations in H during the measurements.

(*To be continued.*)

TROUVE'S AUXANOSCOPE.[1]

In view of the great usefulness of pictorial illustration in elucidating technical discussions in the meetings of scientific societies and in proceedings in courts, everybody interested in such matters will welcome new devices for simplifying such illustration.

Hitherto, for the most part, recourse has been had to projection, either by oxyhydrogen light, or by a voltaic arc. For this a projecting lantern is necessary, as well as a suitable supply of light, and (a more important matter) prepared glass slides to make the projections. It will be easily understood that very often the most eager for discussion shrink from this expense and inconvenience. Mr. Trouvé has designed a very simple little apparatus called the auxanoscope, intended to reduce the difficulty of such illustrations. It is composed (figure 1), of two cylindrical tubes joined at a determined angle, one of which has at its extremity a parabolic reflector with a suitable source of light placed in its focus, and the other an ordinary photographic objective.

At the apex of the angle formed by the two tubes the object or picture to be projected is placed, perhaps a photograph, a design upon paper, a diagram, or the like.

This design, or object, receives the luminous rays thrown out by the light in the focus of the reflector, becomes luminous itself, and forms its focus at some distance before

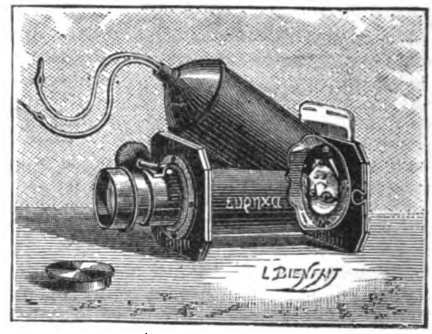


FIGURE 1.

the objective, which latter is arranged in a tube with grooves so as to admit any lengthening necessary. To obtain these effects there is no need of using a very powerful source of light; an ordinary incandescent lamp of several candle power, fed by a suitable number of cells of bichromate battery is sufficient to give satisfactory

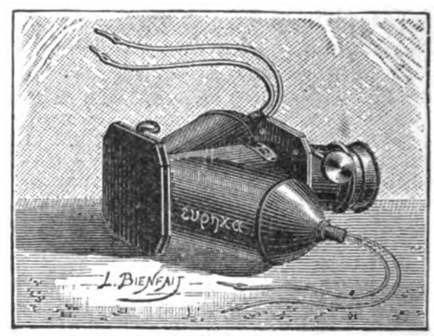

FIGURE 2.

results. Finally, to augment still further the effects produced, Mr. Trouvé has arranged (figure 3), on the other side of the central tube, a third similar to the first, and furnished like it with an incandescent lamp placed in the focus of a second parabolic reflector.

This apparatus may be applied to opaque bodies, which are thus lighted up in front. For transparent substances

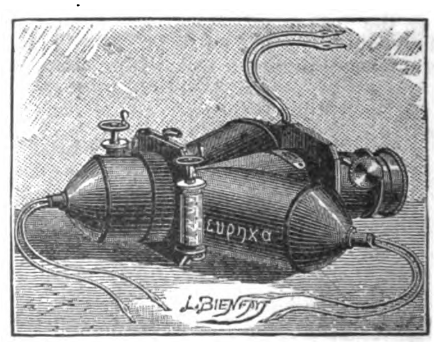

FIGURE 3.

a small reflector is applied on the extension of the tube containing the objective, and lights the substance by transparency. This little arrangement, called the *electric auxanoscope*, from its simplicity, will certainly be appreciated for demonstrations made in public, and also must replace advantageously the *old magic lantern* of our fathers.

1. Translated and abridged from *L'Electricien* of April 14th, 1888.

ABSTRACTS AND EXTRACTS.

ELECTROLYSIS OF IRON SALTS.

BY ALEXANDER WATT.

(Continued from page 261.)

Magnesio-Citrate of Iron.—The electrolyte was formed by dissolving freshly precipitated carbonate of iron in a strong hot solution of citric acid and then adding hydrated carbonate of magnesia until the solution was nearly neutral. The liquid, when cold, was diluted with about twice its bulk of water. With a current from two Daniells a good deposit of iron, but of a greyish white color, was at once obtained upon a copper plate. After a short immersion the coating became streaky and of a dark color; two more cells were then connected, and an addition of citric acid made to the bath, when the character of the deposit was greatly improved, and it soon assumed a fairly good white color, and adhered well to the copper surface. This solution, however, like the sodio-citrate, is inferior to the simple protocitrate, from which much better results can be obtained.

Borate of Iron.—To prepare a solution of this salt a quantity of freshly precipitated and moist carbonate of iron was digested for some time in a nearly boiling solution of boracic acid. Although the carbonate is but sparingly soluble in this acid, the resulting solution, when diluted with about twice its bulk of water, formed an electrolyte from which a good bright deposit of iron was obtained upon both sides of a copper plate immediately after immersion. The current from five Daniells was used, and the surface of the electrodes was about equal. During the electrolysis the anode kept perfectly bright and clean, and the deposit maintained a uniformly bright surface throughout the trial. It should be mentioned that an excess of boracic acid was given to the liquid.

Sulphates of Iron and Soda.—A solution of the mixed salts was prepared by adding to a solution of sulphate of iron (one ounce of sulphate in 10 ounces of water) about an equal quantity of a solution of sulphate of soda. With the current from five Daniells, and about equal electrode surface, a fine white and uniform coating of iron was obtained upon a copper plate a few seconds after immersion, and the deposition proceeded with perfect uniformity and with great rapidity, a good coating being received upon the plate in about a quarter of an hour. It seems probable that a bath prepared from these salts, with such modification of density as a larger trial might suggest, would prove a useful electrolyte for depositing iron for practical purposes. A second plate was next placed in the bath and allowed to remain for a longer period, when, as before, a perfectly uniform deposit was obtained, while the anode still retained its brightness, and exhibited signs of having been freely acted upon. On examining the solution (which was faintly acid) after the trial there was no evidence of oxidation on its surface. It should be mentioned that the deposit took place on both sides of the cathode, the back of the plate being fairly coated with iron a few seconds after immersion, indicating that this bath is a very good conductor. In many of the solutions of iron salts which I have electrolyzed during these experiments, the front of the cathode—that is, the surface facing the anode—alone received a deposit of metal, while in some instances there was only a partial disposition for the metal to deposit on the back of the plate. In several instances the film positively refused to make its appearance on this surface of the negative electrode. In the present case the deposition commenced at the bottom of the plate and continued upward, which, as I have shown, is not always the case; indeed, I have known many instances in which it has been practically impossible to obtain a coating of metal upon the corners and lower edges of the cathode, even when the upper part of the plate has been coated with metal. When this peculiarity shows itself, however, it is a sure sign that the solution is an indifferent conductor.

Pyrophosphate of Iron.—A solution of this salt was prepared as follows:—A moderately strong solution of the pyrophosphate of soda was first obtained, and into this was poured, gradually, a solution of persulphate of iron. The mixture being well stirred, the resulting precipitate rapidly became dissolved, when fresh additions of the iron salt were added to nearly the point of saturation. The solution thus obtained was worked with five Daniells. In a few moments there was a moderate evolution of gas, and a dark brown salt became formed at the cathode. The plate after remaining in the bath for about five minutes was examined, when a dark blue horizontal streak of iron appeared on its upper surface, but no metal had deposited upon the remainder of the plate. On raising the anode it was found to be covered with a thick white and dense mass, which had apparently stopped the passage of the current. Beyond these effects no result could be obtained from this solution.

Chlorides of Iron and Magnesium.—To prepare this bath a solution of acid protochloride of iron was first neutralized with carbonate of magnesia and then filtered. The clear liquor was then electrolyzed with the current from three small Daniell cells, in series, when a dark bluish-grey film was immediately obtained upon a brass cathode. Two cells were next tried, when, as before, the deposit took place instantaneously; the solution was now diluted and a fresh plate immersed. The deposition being still too quick, however, more water was added to the bath, when the character of the deposit improved. The current from a single cell was next tried, with still further advantage, since the film now became whiter and more bright. With the single cell there was but little evolution of gas, but in a short time the liquid became murky. A moderate addition of a solution of chloride of magnesium was now made, and the solution well stirred, when it at once became light and clear. A freshly prepared brass plate was then immersed, which soon became coated with a film of iron of a good white color and very adherent. The deposition being still rather more speedy than was desirable for a good reguline and tenacious deposit, the anode surface was reduced to about equal that of the negative electrode, when the deposit took place more gradually, and the character of the film greatly improved. There was, however, considerably more gas eliminated after the addition of the magnesium salt, and the hydrogen bubbles had a tendency to rest upon the plate.

Chlorides of Iron and Sodium.—A moderately strong solution of the protochloride of iron was first made, and to this was gradually added a strong solution of carbonate of soda, until the liquid was neutral to litmus paper. With the current from three Daniells, and large anode surface, a partial film of iron slowly formed on the brass cathode, and at the same time a white gelatinous deposit appeared on the plate, which was ejected from the surface by the hydrogen (which was very copious), and finally deposited at the bottom of the vessel. A few drops of hydrochloric acid were now added to the liquid, when the solution became clear; the anode surface was also increased, when a bright film of iron slowly formed upon the plate. The solution was next diluted with about double its volume of water, and a small quantity of common salt added and dissolved in the liquid, when the deposition immediately improved in every way, being not only more rapid, but the film became perfectly bright, and of a brilliantly white color. It was found necessary now, however, to reduce the anode surface considerably, little more than half that of the cathode being sufficient. It was next determined to reduce the number of cells, one and two cells respectively being tried; but the most suitable current was obtained from the latter number of cells in series, and equal electrode surface, with which a fine white and remarkably bright and adherent film was obtained at a fair rate of deposit. Although this solution of the mixed salts is capable of yielding very favorable results, it is scarcely one that could be recommended for practical working, inasmuch as it might be somewhat uncertain in its performance as an electrolyte, unless the current and anode surface were regulated, as we have seen, to a degree of nicety that is scarcely so necessary with some of the solutions described in the former papers of this series.

Nitrates of Iron and Potassa.—This bath was prepared by adding to a solution of protonitrate of iron one of nitrate of potassa, the compound solution being of moderate strength. The current from a single Daniell cell was first tried, when a dull, opaque film of a non-metallic character—probably a subsalt of iron—was obtained upon the cathode. Two cells were next tried, with similar results. A third cell was then connected in series, when after a short immersion of a brass cathode, a dark green salt formed upon its surface, and in about two minutes after accumulated on the plate as a green spongy mass, finally falling off the surface and depositing at the bottom of the vessel. This green salt, when exposed to the air, oxidized with great rapidity, forming a rusty compound of somewhat brighter color than ordinary rust of iron. No metallic deposit of iron could be obtained from this bath with any modification that suggested itself, either in strength of current or density of the liquid, so the experiment was abandoned. It should be mentioned, however, that the dark green salt referred to sometimes formed an adherent film—apparently transparent—which could only be detached from the plate by force, while the remainder of the same material, which formed the upper layer of the deposit, came away from the plate spontaneously, or was easily removed by wiping it off with the finger. I may mention the fact that I have frequently met with the same dark green, semi-adherent substance when electrolyzing some of the persalts of iron.

Iodide of Iron.—This salt was first prepared by digesting fine iron wire in warm water, to which was added a quantity of iodine, the containing vessel being repeatedly shaken at intervals of an hour or so, and then allowed to repose until the following day, by which time the iodine had disappeared, and the solution was ready for use. The liquid, which had a greenish tint, was moderately diluted with water, and then electrolyzed with two Daniell cells, when a film, of a blued steel color, was promptly obtained upon a brass cathode. A single cell was next tried, when the deposit was still very rapid, of a dark color and dull, but very adherent. After a time the solution became turbid from decomposition, and the experiment was then discontinued.

Ferrocyanide of Potassium and Iron (Soluble Prussian Blue).—A solution of this double salt was formed by adding a solution

of perchloride of iron to one of ferrocyanide of potassium, the latter being in excess. The precipitate of Prussian blue thus obtained was, after filtering, dissolved in water, and the resulting liquid then gently warmed and electrolyzed with a current from one, up to five, Daniells, but no deposit of iron could be obtained upon a brass cathode. The liquid was then heated to about 120° F., but with no better result, so the experiment was pursued no farther.

Tannate of Iron.—This electrolyte was prepared by cautiously adding a solution of tannic acid to one of perchloride of iron, avoiding an excess of the former. The black liquid thus obtained was then heated and electrolyzed with the current from four Daniells, when a slight metallic film was received upon a brass plate, but only in patches, while other parts of the plate became coated with a dark brown, tolerably adherent non-metallic film. A good deal of gas was liberated at both poles, which rested on the surface of the liquid in very large bubbles, and when the cathode was lifted out of the bath these came away with it and remained for some time upon its surface without breaking, a peculiarity before observed in respect of the electrolysis of the pernitrate of iron solution. The bath was now heated, but with little or no advantage, since nothing but a trifling deposit of iron, in parts of the plate only, could be obtained, while a gelatinous deposit formed upon the plate, indicating that the solution was gradually decomposing.

Gallate of Iron.—A solution of gallic acid was gradually added to one of perchloride of iron, and the blue black liquid thus obtained was electrolyzed with the current from four Daniells. The results were of a precisely similar character to the preceding, except that there was no actual film of metallic iron; the only deposit obtainable was a brown non-metallic film.

Potassio-oxalate of Iron.—A solution of this salt was prepared by Graham's method, namely, by dissolving hydrated peroxide of iron in a solution of binoxalate of potassa, a pale green solution being obtained, which was first electrolyzed with a single Daniell, when an opaque, white and firmly adherent insoluble salt was deposited upon the cathode. Three cells were then tried, when a tardy deposit of metallic iron, of fairly good color, appeared on the surface of a freshly prepared plate. The liquid was afterwards heated, and in this state it yielded a very white film of iron, which was firmly adherent. It is a singular fact that when the plate was first put into the bath after it had been heated, that the same opaque film, before noticed, at once appeared on its surface, but when the plate was allowed to rest undisturbed for a few minutes, this film disappeared, and the metallic deposit then occupied its place.

Pertartrate of Iron.—A bath was prepared from this salt by digesting recently precipitated and moist hydrated peroxide of iron in a boiling solution of tartaric acid. The resulting liquid, which, after filtration, was of a bright yellow color, was diluted, and then tried with a current from four Daniells, when there was a brisk liberation of hydrogen, but no deposit of metal appeared on the cathode. The strength of the current was then gradually reduced, until finally a single cell was tried, but without any result. The liquid was then heated, and the experiment repeated with the same variations of current strength, but only a slight film of iron could be obtained with the warm solution, four cells being used, by briskly moving the cathode about in the bath; when stationary, no deposit whatever could be obtained. It was next determined to try the effect of dilution, as I had previously found that metallic deposits could be obtained from highly attenuated solutions of persalts of iron, which were impossible with stronger liquids. Water was now added until the bath had become diluted to about 10 times its original volume. With four Daniells and increased anode surface, a bright film of metallic iron soon appeared upon a brass plate, except at the lower corners, where there was no deposit. Farther additions of water were afterwards given, a fresh plate being immersed after each addition, until the solution had become weakened to the extent of about 20 times its original bulk, when even in this very dilute condition films of metallic iron were obtained. The results of this experiment clearly show that under certain conditions of the electrolyte—extreme dilution, apparently being the most essential condition—solutions of iron persalts will give up their metal by electrolysis; and if this has hitherto been considered unattainable it must be evident that such necessary conditions have not been fulfilled by those who have experimented with these salts.—*The Electrician* (London).

ADVANTAGES OF ELECTRICITY FOR RAILROAD WORK.

THE rapid advances of the application of electricity to street car traction brings up the question whether we cannot in the near future look to the displacement of the steam locomotive by the electric motor. The conditions of street car and railroad work are different: in the first, electricity is called upon to displace horses, an extremely costly motive power; in the second, it must displace steam. That it can economically replace horses has been shown by a number of electric tramways at present in operation. The only question is, will considerations of safety and æsthetics allow the current to be economically conveyed to the cars? For instance: in the Sprague Electric Railway in Richmond, using an overhead conductor, it is costing for power about $1.70 per day per car, the cars averaging over 80 miles. This is for only 20 cars. When the full complement is running, the cost will be reduced, probably to about $1.50 per car per day. This cost is to be compared with the $5 or $6 that must be allowed per car per day for horses, at an average of, say, 60 miles per car per day. If the overhead system could be used, then, in all of our cities, there would be no doubt as to the results as far as street car traction goes. When it comes to ordinary railroad work, the state of affairs is very different. The question is, shall we substitute for steam, used directly, a power which is in the first place derived from steam, and which suffers the losses due to at least two transformations before it is utilized in driving the train? As far as mere economy of power production goes, the question is easily answered: the efficiency of a stationary steam plant is greater than that of a locomotive engine; and the cost of a horse-power delivered to the driving axles of the train by the electric motor would not be more for coal, attendance, and depreciation, than the same power from the locomotive, even after allowing for all the losses in the different transformations. The advantages of the electric motor are these: the driving machinery is the simplest that it is possible to conceive of: the armature of the motor would be fitted directly on the car axle, while the field magnets would rest on the truck. Each axle would have its motor, and in a train every second or third car would be a motor car. One advantage of this has been pointed out, first, probably, by Professor George Forbes. Taking a six-car train, we would have the traction, not of four wheels, but of 16, supposing two motor cars. This will enable us to make any speed that safety will allow, to start quickly, and to take at high speeds grades that at present are inadmissible. In fact, we can dispense with a great deal of the grading that makes the construction of railroad lines so costly. Again: on the down grades we can make our motors into dynamos feeding current into the line,—a plan due, I think, to Mr. Sprague,—instead of wasting energy by braking the wheels; and we can in the same way brake the cars when stopping. The advantages, then, are great simplicity, increased traction, allowing an increase of speed and a decrease in the cost of constructing the road, recovery of energy on down grades and in stopping. As compared with city electric tramways, such as are now in use, railroads would have the advantages of simplicity, in not requiring any gearing between the motor and car axle, and in allowing any economical means of conducting the current to the car, and the employment of high electromotive forces. There is one great disadvantage, however, that the future may remove, but which at present is serious. A station supplying any portion of the line will have to have a capacity equal to the maximum work that will be required of it at any time, while the mean work might be very much less than this. As the maximum may differ from the average work five or six times, we would have to equip stations of five or six times the present capacity of the locomotives, at a cost that would throw the balance in favor of the present system, unless there happened to be very considerable sources of natural power along the line. The remedy for this—a remedy which cannot be at present applied—is in equipping the stations with storage batteries; charging them when the required power is below the average, drawing from them when it is above. We may say, then, that with long-distance direct lighting and electric tramways, electric railways wait the development of a more perfect storage battery to be successful.—*Science.*

. . . . You might as well try to stop the sea as to stop the use of alternating machines.—*Gisbert Kapp.*

. . . . The Standard Oil Company have capable men whose only study is to reduce the cost of the output. We all know the result.—*The Millstone.*

. . . . If secondary batteries were good enough I should never dream of putting down alternating transformers, but I have never seen a good battery.—*Gisbert Kapp.*

. . . . You can get but a certain number of volts out of any combination of two substances, no matter what they are; you can calculate just the possible amount, in volts, and you can get no more.—*C. S. Bradley.*

. . . . A nation of 60,000,000 people, in whose territory are the finest copper mines, producing every year enough copper of the very best quality to supply the home demand, must now go on its knees to a speculator in Paris for the copper which it needs.

. . . . It is clear that in all directions distribution by means of transformers is the order of the day, and whether it be by alternating current machines on the one hand, or by accumulators on the other, or by motor-dynamos, it is clear that transformers will be the means of distribution.—*Silvanus P. Thompson.*

THE ELECTROMOTIVE FORCE OF MAGNETIZATION.[1]

BY EDWARD L. NICHOLS AND WILLIAM S. FRANKLIN.

AT the Ann Arbor meeting of the American Association for the Advancement of Science, we described some singular modifications in the relation of iron to acids which occur when the reaction takes place within the magnetic field. The present paper deals with the behavior of iron when that metal acts as one electrode in a voltaic circuit, and is at the same time subjected to magnetization.

A galvanometer placed in a circuit consisting of two electrodes of iron, metallically connected on the one hand, and dipping, on the other, into a cell containing any liquid capable of dissolving them, will indicate the existence of a current whenever the reaction between the metal and the liquid differs in character or rapidity at the two terminals. There are always at work a number of causes of such inequality of action, and the electromotive force between iron poles in any liquid which attacks them freely is not inconsiderable. It amounts as a rule to several thousandths of a volt; and even when special precautions have been taken to secure homogeneity in the elements of the circuit, a sensitive galvanometer will not fail to show the existence of a current. If one of the terminals be placed within a magnetic field, new differences of potential will be developed, both from the magnetization of the iron and from the change in the chemical relations between the metal within the field and the liquid. This electromotive force we have proposed to call *the electromotive force of magnetization.*

With the exception of two papers by Dr. Theodor Gross,[2] of Berlin, which came to our notice too late to enable us to take advantage of their valuable contents in our investigation, we know of no observations of the effect of magnetization upon the voltaic behavior of iron. Dr. Gross's research deals chiefly with the electromotive force due to the magnetization of the iron, and touches only incidentally upon the nature of the currents produced when one of a pair of iron electrodes has its electro-chemical relations to the solution modified by being placed within the magnetic field. It is with the latter phase of the subject, principally, that our experiments have to do.

The first form of cell, which we used, consisted of two glass tubes, *a* and *b* (figure 1), about 1^{cm} in diameter and 10^{cm} long.

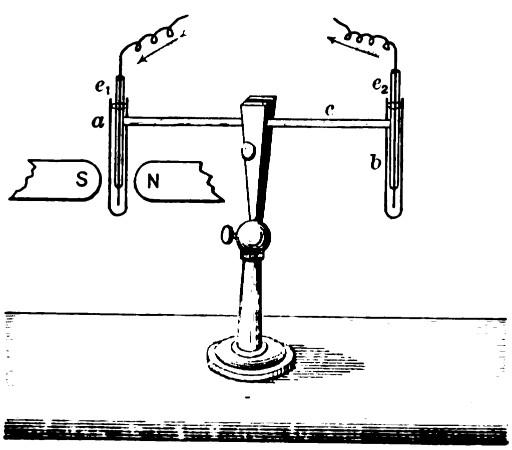

Fig. 1.

These were closed at the lower end and were connected by a narrower glass tube (*c*), about 50^{cm} in length. The electrodes, e_1 and e_2, consisting of soft-iron wire were inserted through the open ends of *a* and *b*. They were exposed to the liquid for about 1^{cm} at their lower ends. When this apparatus was filled with a liquid capable of dissolving iron, it formed a single cell, one terminal of which could be placed between the poles of an electromagnet, while the other was well outside of the field. When the free ends of the wires, e_1 and e_2, were connected through a sensitive galvanometer, it was found that, although the terminals were taken from the same piece of wire, and were immersed in the same liquid, a measurable current was always flowing in the circuit. The electromotive force was constant neither in amount nor in direction. In many liquids it changed but slowly, however, and could be balanced by means of a variable counter-electromotive force introduced into the circuit. For this purpose a Daniell's cell was placed in circuit with two variable resistances, R and *r* (figure 2). The cell with iron electrodes was shunted around *r*, and the ratio R/*r* was so adjusted that the current in the shunt circuit, due to the Daniell's cell, was just sufficient to reduce the galvanometer deflection to zero. The galvanometer could then be sensitized to any desired extent, but the fluctuations in the electromotive force of the iron cell were such that the balance was never more than momentarily maintained, and the galvanometer drifted continually.

In very weak acids and in solutions of $FeSO_4$, $FeCl_2$, NH_4Cl, and similar salts, these fluctuations were not such as to preclude the possibility of making measurements, but in concentrated acids they were for the most part so rapid and irregular as to put galvanometer readings out of the question. In nitric acid, of considerable strength, these fluctuations were so remarkable as to deserve special mention. The electromotive force, amounting to a considerable fraction of a volt, changed sign continually, carrying the spot of light across the galvanometer scale, to and fro, with great rapidity. The frequent and irregular oscillations con-

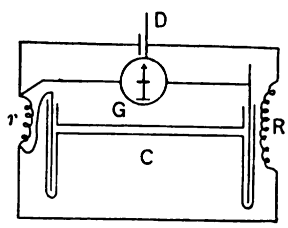

Fig. 2.

tinued with undiminished violence until the electrodes were entirely dissolved or the acid nearly neutralized. Upon first closing the circuit one of the iron terminals would be slightly more active than its fellow. The tendency of the less active electrode would then be to protect the other from the attack of the acid, rendering it temporarily passive, as a piece of platinum would do under the same circumstances. The passive terminal would then react in like manner upon the first, and electromotive force would be reversed again and again until the electrodes were consumed.

In those cases in which the fluctuations were not such as to make the attempt at compensation ineffectual, we were able to make measurements of the initial electromotive force of the cell and of the changes in electromotive force caused by the action of the magnet.

One of the iron terminals was placed between the poles of a large electro-magnet. To obviate any direct effect of the magnet upon the galvanometer needle, the galvanometer was set up in a room several hundred feet distant from that in which the former instrument was located. The "iron" cell having been connected with the wires leading to the galvanometer room, the initial electromotive force was balanced by the method already described, and the galvanometer was brought to the desired degree of sensitiveness by means of a governing magnet. One observer then proceeded to made galvanometer readings at intervals of 15 seconds, while another magnetized and demagnetized the electro-magnet every two or three minutes, reversing the magnetizing current each time. The electro-magnet in question has been described in a previous paper.

Like most large instruments of the kind, it required several seconds after the circuit had been closed to attain its full strength; and it retained considerable residual magnetism when the circuit was broken. By the following very simple device, however, the residual magnetism was almost entirely destroyed. A reversing switch of Poggendorff's pattern and an ordinary telegraph key were placed in series in the magnetizing circuit. While the magnet was in function, a piece of soft iron wire about 1^{cm} long was suspended by magnetic attraction from the underside of one of the pole-pieces. The wire served as an indicator of the magnetic condition of the poles. Upon breaking circuit with the key the residual magnetism was sufficient to hold it in position. When, however, the current was first reversed by means of the Poggendorff switch, and then broken at the instant when the magnet was passing through the condition of neutrality, the proper moment being indicated by the dropping of the suspended wire, the magnet was left thoroughly demagnetized. The interval of time between reversal of the current and neutrality was about two seconds.

After each series of readings, the galvanometer was calibrated, the resistance of the iron cell was measured and the strength of the magnetic field was estimated by a modification of Rowland's method. The instrument used in most of these measurements was Edelmann's form of the Wiedemann galvanometer, read with telescope and scale. For some experiments in which a high degree of sensitiveness was necessary a Thomson reflecting galvanometer of 2500 ohms resistance was used.

It was found possible by this method, excepting when the fluctuations in the initial electromotive force of the cell were very marked, to detect changes amounting to much less than .00001 volts.

We experimented with a variety of reagents, including nitric

1. Paper read at the New York meeting of the American Association for the Advancement of Science, August 11, 1887. From the *American Journal of Science*, vol. xxxv, April, 1888.

hydrochloric and sulphuric acids; ferrous sulphate, ferrous chloride, and ammonium chloride, in aqueous solutions, and finally, sulphuric acid, to which potassium bichromate had been added, and hydrochloric acid containing potassium chlorate. In every case there was unmistakable evidence of the development of a permanent electromotive force due to the influence of the magnet. The smallest effect, .000008 volts, was observed with terminals in concentrated nitric acid, the iron being passive—the largest effect in those solutions in which rapid oxidation took place. In a solution consisting of dilute sulphuric acid containing potassium bichromate, the electromotive force of magnetization amounted to .039 volts. In the same acid, the concentrated sulphuric acid of commerce diluted with 10 parts of water, without the addition of the potassium bichromate, it was only .0005 volts. Concentrated hydrochloric acid (sp. gr. 1.1768), gave .003 volts, the same acid, diluted with four parts of water, only .00002. When potassium chlorate was added to the dilute acid, the effect due to the magnet became very marked, amounting certainly to several hundredths of a volt; but the fluctuations in the initial electromotive force were such as to make readings impossible. In nitric acid diluted with nine parts of water the effect was also very large, but it was so masked by the initial fluctuations described in a previous paragraph, that no quantitative determinations were secured. The strength of field during these experiments was about 10,000 H.

In the hope of eliminating these fluctuations in the initial electromotive force, two modifications of our apparatus were made. In the first, it was so arranged that a current of the fresh solution passed through both arms of the cell, and the products of the reaction were carried away from the neighborhood of the terminals almost as soon as formed. In the second modification, terminals were prepared, the surface of which consisted of pure iron, electrolytically deposited. When these prepared terminals were used, the fluctuations were somewhat less marked than when the original surface of the iron wire was exposed, but the adoption of these two modifications led to no new results. A more important modification consisted in the substitution of platinum or copper for the iron terminal outside of the field. These metals being unaffected by the magnet, could be placed in close proximity to the magnetized terminal; the internal resistance of the cell was thereby greatly diminished and its form simplified. The iron-copper and iron-platinum cells were placed between the poles of the electro-magnet, and the investigation consisted in determining the electromotive force before and after the magnet had been made active. The most satisfactory results were obtained with a cell patterned after the Daniell battery—a two-fluid cell in which copper immersed in sulphate of copper was separated from the iron pole by a porous diaphragm, the iron being submerged in a solution of ferrous sulphate or of ferrous chloride. A cell of this description in which a neutral solution of ferrous sulphate surrounded the iron, and which possessed an initial electromotive force of .6072 volts, increased to .6361 volts when placed within the field. Similar results were obtained with other solutions.

In the various forms of apparatus already described the currents due to magnetic action did not always flow in the same direction. The iron terminal within the field would sometimes act as zinc toward the unmagnetized electrode, sometimes as platinum. To determine the law governing the direction of the currents due to the electromotive force of magnetization we tried the following experiments. The terminals of iron wire used in our original apparatus were supplanted by cylinders of soft Norway iron 1^{cm} long and 4^{mm} in diameter. These were placed horizontally in the solution and were attached to the end of copper wires. The wire was in each case thoroughly insulated from the liquid, and the iron bar itself was protected by a coating of wax with the exception of a single portion of its surface, which to the extent of a few square millimeters was exposed to the action of the liquid. Under these conditions, the direction of the electromotive force developed between the terminal within the field and a similar one outside was found to depend upon the portion of the bar exposed and the position of the latter with reference to the lines of force. Whenever the exposed surface was in the neighborhood of an induced pole within the soft iron electrode it became in its relations to iron outside of the field, as zinc to platinum. Whenever, on the contrary, the exposed surface was situated in a neutral portion of the bar, it became as platinum in its relations to unmagnetized iron. When platinum, carbon or copper was substituted for the unmagnetized electrode the electromotive force of the cell thus formed was increased by magnetization, in the case in which a pole of the iron terminal was exposed to the liquid and diminished by magnetization when the surface acted upon lay in the middle of the bar. A reversal of direction in the current flowing between such a bar of iron in the field, one end of the bar being exposed to action, and an unmagnetized iron terminal, could be produced by turning the former in the field. When the axis of the bar was parallel to the lines of force and it was accordingly magnetized longitudinally, it acted as a zinc pole, the current flowing from its surface through the cell to the unmagnetized electrode. When turned through 90° upon an axis perpendicular to the line joining the poles of the electro-magnet, the bar became magnetized transversely and the direction of the current was reversed.

Between bars lying with their axis parallel to the lines of force, the end of one and the middle of the other of which was exposed, the effect was more marked than between either of them and a piece of unmagnetized iron; the bar with exposed pole acting as zinc, that exposed in the middle as platinum.

After having determined the conditions which govern the direction of the current, we turned our attention to the relation between the strength of the magnetic field and the electromotive force which it is capable of producing. The cell selected for this work was an iron-platinum element, containing a solution of potassium bichromate in dilute sulphuric acid. In this liquid the electromotive force of magnetization was so marked that when the cell was placed between the pole-pieces of the electro-magnet the influence of the residual magnetism of the latter upon its electromotive force could easily be detected. Measurements were made in fields varying in intensity between 2,000 H., and 20,000 H. The results are given in the following table. They show the manner in which the effect in question increases with the strength of the field.

TABLE.

Influence of the strength of field upon the electromotive force of magnetization.

Strength of field.	E. M. F. in volts.
2,000 H.	.0008 volts.
3,600	.0045
5,040	.0208
7,770	.0386
8,400	.0424
12.750	.0487
16,300	.0510
19,700	.0680

We had noticed in the course of our experiments that a layer of the more or less magnetic solution of the salts of iron, produced by the reaction, always gathered around the induced poles of the electrode within the field. In this way a two-fluid battery was formed between the iron within the field and that outside, whenever the surface nearest the poles of the magnetized electrode was exposed. The terminal within the field was thus surrounded by a concentrated solution of its own salts, and was in a measure protected against the direct attack of the acid. In the case, however, in which a neutral portion of the electrode within the field was exposed, the products of the reaction were continually withdrawn by magnetic attraction towards the pole-pieces, and the surface was left more open to attack than the opposing electrode outside of the field.

For the purpose of ascertaining whether this arrangement of the solution in the field would tend to produce the effects which have been described, measurements were made of a variety of batteries in which iron formed one electrode. The results were such as to make it evident that the influence of the magnet could, in part at least, be thus explained. An iron-carbon cell, the liquid being nitric acid diluted with one part of water, was found to have an E. M. F. of .88 volts. When the acid was placed in a porous cup, containing the carbon pole, and the iron was submerged in weak sulphuric acid (1:10), the E. M. F. rose to 1.83 volts. The same metals in dilute sulphuric acid containing potassium bichromate gave 1.05 volts which was increased to 1.32 by placing the carbon and bichromate solution in a porous cup and the iron in dilute sulphuric acid. A cell with iron and platinum, in a solution consisting of 200^{cc} of strong hydrochloric acid, 200^{cc} of water and 20^{grms} of potassium chlorate, gave 1.17 volts. When converted into a two-fluid battery, the iron submerged in weak sulphuric acid, the platinum in the above solution, the E. M. F. became 1.39 volts. When the iron in the last case was submerged in dilute hydrochloric acid the result was nearly the same, the E. M. F. being 1.41 volts. In sulphuric acid containing potassium permanganate the same metals gave 1.44 volts, which rose to 1.60 volts when the platinum and solution were placed in a porous cup and the iron was dipped in sulphuric acid containing no oxidizing agent. Iron and platinum in ferrous chloride showed only .74 volts, but a two-fluid battery with iron—dilute hydrochloric acid—ferrous chloride—platinum gave 1.07.

In all these cells the electromotive force obtained by the solution of iron with ferric reaction was smaller than when a ferrous reaction occurred. The application of this fact in the explanation of the electromotive force of magnetization is very manifest. When the *poles* of an electrode within the magnetic field are exposed to action, the gathering of the salts of iron around the exposed surface tends to bring about a change from *ferric* to *ferrous* reaction and to *increase* the electromotive force. A corresponding *decrease* follows when a neutral surface is exposed within the field. The extent to which the electromotive force of a cell in which a ferric reaction is taking place may be reduced by briskly stirring the solution and exposing the surface

of the iron to the fresh acid, thus doing mechanically what is done magnetically when the reaction occurs, at a neutral surface, within the field, was shown by the following experiment. A one-fluid cell, consisting of iron and platinum in nitric acid diluted with four parts of water, had an electromotive force of 1.07 volts. Stirring reduced it to .95 volts. When left undisturbed it immediately regained its former intensity.

The electromotive force developed between the poles of one iron electrode placed within the magnetic field and the neutral parts of a similar electrode in the same cell, will also exist between the poles and intermediate portions of a single piece of iron. Consequently there will always be local action between different portions of the surface of iron exposed to chemical action within the field, the currents passing through the liquid from the regions nearest the induced poles.

It is doubtless to this local voltaic action, which has its source in the electromotive force of magnetization, that the various phenomena, described in our papers on *the chemical behavior of iron in the magnetic field*, and on *the destruction of the passivity of iron by magnetization*, are to be ascribed.

THE COMPARATIVE VALUE OF THE ALTERNATING TRANSFORMER AND CONTINUOUS CURRENT SYSTEMS FOR CENTRAL STATION LIGHTING.[1]

BY F. B. BADT.

We have heard three papers on apparently the same subject, though each of these papers was named differently by its author. I know a good many of you are under the impression that I will be an advocate of the alternating system, against the continuous current system; but such is not the case. In the title I have given my paper, I have narrowed this discussion to its proper limits. I do not believe, by any means, that the alternating transformer system will be substituted for isolated lighting, or for lighting within moderate distances, but I do believe that for an economical central station lighting system, the alternating transformer system is the best in existence. This remark may seem superfluous, but lighting within short distances, and even isolated lighting, has been dragged into the discussion on this subject. Although the author of the first paper read apparently tried to show that the only practical system for central station lighting of to-day, is the three-wire system of, say, not exceeding 230 volts, I propose to show to you that this attempt is not even consistent with the practice of the company this gentleman represents. In the first place, let me read an abstract of a circular concerning the Edison municipal system.

I quote: "The Edison municipal system has especially been devised to meet all the requirements of perfect outdoor illumination. * * * The current used in this system is of high tension (1,200 volts), which would be unsafe to introduce into dwellings, hotels, stores, or buildings of any character, where the wires and sockets are liable to be handled by inexperienced persons, but when they are stretched on poles in the open air, and the lamps are attended by persons who have been properly trained, all danger to the public ceases. If desired, the circuits for this system can be laid underground at a reasonable cost.

"Each lamp is screwed into a socket, which is protected from rain by a metal hood, and in the upper part of the hood is placed an apparatus that closes the circuit whenever a lamp carbon breaks, thus keeping the continuity of circuit uninterrupted. At the same time an instrument in the station indicates the breakage, so that the attendant may be sent out with another lamp to replace the broken one."

N. B. I hope he is provided with a bicycle.

Secondly, I will quote from a paper read by a gentleman during the Edison convention in Chicago, February, 1888:

"A modification of the Edison three-wire system was mentioned where two Edison 600-volt, 26 ampere dynamos, furnished current for several hundred lights; five 110-volt lamps being used in series on either side. The dynamos run without sparking, there is no more evidence of high pressure visible at this plant, or in the municipal 1,200-volt machines, than with 125-volt dynamos. There is probably no more perfect plant running than this, which has been in service since the middle of last year." And, again, "Within proper limits, the principle of high pressure is not absurd or inconsistent with correct principles of future progress. The idea underlying the transformer is the logical outcome of experience, but thus far we have no satisfactory application to general commercial uses, excepting, possibly through the electric motor."

Now, gentlemen, in both cases an electromotive force of 1,200 volts is employed, and they call the last-named system a "modification of the Edison three-wire system." If what we heard in the first paper is true, why does the same company employ an electromotive force up to 1,200 volts? The 1,200 volt three-wire system, as I understand it, is used for store lighting, and is introduced into houses; while in the pamphlet concerning the municipal system, the introduction of 1,200 volts into houses is condemned.

Where is logic? Where is consistency? I cannot see it, but I hope that during the discussion which probably will follow the reading of this paper, some of the gentlemen will be kind enough to explain it to me. I am well satisfied that there is a tendency, even among the most ardent advocates and admirers of the low tension system for central station plants, to occasionally raise the electromotive force when they cannot raise the necessary money to buy copper enough for their feeders and mains on the 230 volt three-wire plan. There is certainly less objection to even a 1,000 volt alternating transformer system than to the introduction of a 1,200 volt continuous current into houses.

Now, gentlemen, what I believe is that all these systems, namely: Multiple arc, three-wire and multiple series *continuous* current, as well as multiple arc, multiple series and transformer *alternating* system, are good in themselves, and that it is our task to find the proper places and the proper conditions for each. Each one has it place. We all agree that for isolated lighting, the multiple arc system is the best; whether continuous or alternating is a question which I do not want to answer here. For longer distances we will properly use according to circumstances, multiple series of two lamps (three-wire) or multiple series of more lamps, again either continuous or alternating. And for still longer distances, we will employ a general system of incandescent lighting, where all points, near and far, must be reached in order to supply *all* customers, the *alternating transformer* system. These few remarks will probably outline my ideas of the application of the different systems of incandescent lighting under different conditions. What I want to show, however to-night, is the comparative value of the alternating transformer system and the continuous three-wire system for central station lighting. I will adhere to the points named in the previous papers, namely:

First—First cost.
Second—Economy, efficiency and depreciation.
Third—Reliability.
Fourth—Variety and value of the possible sources of revenue.
Fifth—Safety to life.
Sixth—Effects upon existing property.

First and Secondly—First cost and economy. (Efficiency and depreciation.)

It was shown in the first paper that the cost of the conductors transmitting a given amount of energy at given loss for a given distance varies inversely as the square of the initial electromotive force employed. In the accompanying figure, circles 1 to 6, show the combined cross-section of copper feeders at five per cent. loss for 500 16 c. p. 110-volt lamps at a distance of one mile. They represent:

Circle 1—Multiple arc. (110 volts.)
Circle 2—Three-wire system, according to Professor Forbes (220 volts).
Circle 3—Three-wire system, according to H. Ward Leonard (220 volts).
Circle 4—Groups of five 110-volt lamps in series (550 volts).
Circle 5—Alternating transformer system (1,000 volts).
Circle 6—Alternating transformer system (2,000 volts).
The ratio is as follows:

TABLE No. 1.

Fig.	1	2	3	4	5	6
System.	Multiple Arc.	Three-wire. Forbes.	Three-wire. H. W. Leonard.	Multiple Series.	Alternating Transformer.	
E. M. F.	110	220	220	550	1,000	2,000
Ratio of cost of feeders.	328	246	108	13	4	1
Cost of feeders per lamp at 5 % loss at one mile	$71.00	$53.00	$23.00	$2.80	$0.85	$0.21

I think this table is perfectly clear without any further explanations. I will repeat, however, the statement made by Mr. Slattery, that according to Professor Forbes (as shown in his paper published in the New York ELECTRICAL ENGINEER, July, 1885), the saving of the three-wire over the multiple arc system is only 25 per cent., and that to assume any more saving may suit American financiers, but is not electrical engineering. The originator of the so-called Edison three-wire system, Dr. Hopkinson, of England, thoroughly coincided with Professor Forbes in this view.

For the sake of argument, however, I will assume whenever I speak of the three-wire system, the figures given by Mr. Leonard, or a saving of 66⅔ per cent. over the multiple arc system.

Table No. 1 also shows the cost of feeders per lamp, at five per cent. loss, at one mile, assuming the cost of copper at 20 cents per pound. In Mr. Leonard's paper the parallel was drawn only between the thousand volt alternating system employing 50-volt

1. Read before the Chicago Electric Club, at a special meeting, April 23, 1888. The fourth of a series of papers upon the subject, "The Continuous Current *vs.* the Alternating Current," before the club.

lamps and the three-wire system employing 110-volt lamps. I hardly think this fair, as it increases the cost of copper wires for the secondary circuits four times the cost of the copper wires in the branches of the three-wire system. In making this comparison the most economical alternating systems employed to-day in Europe and America should be considered. These systems employ an electromotive force in their primary mains of about 2,000 volts and use 110-volt lamps in their secondary circuits. Any improvement which in future should be made in these lamps, will, of course, be an improvement in the alternating transformer system as well as in the three-wire system.

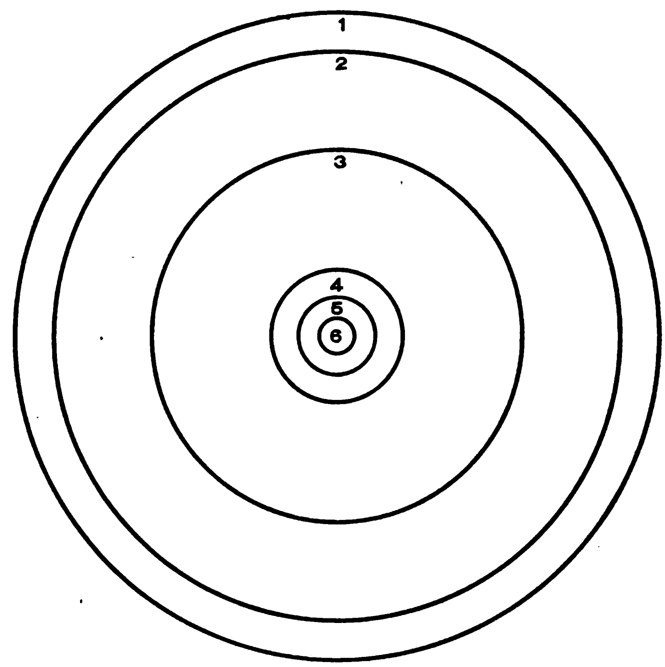
Now, in comparing the cost of the two systems, I will, for the sake of argument, again compare the three-wire system to the 1,000-volt alternating system. Let us assume that the cost of feeders per lamp at a certain distance for a 1,000-volt alternating system at 2½ per cent. the loss is one dollar. Then, according to Mr. Leonard, the cost of the copper for the three-wire system would be $27.50. Table No. 2 gives the cost of the two systems at 2½ per cent., at 5 per cent., at 10 per cent. and at 20 per cent. loss.

TABLE No. 2.

COMPARATIVE COST OF FEEDERS PER LAMP.

Loss in Feeders.	Three-wire System.	1,000 volts alternating System.	Difference of cost between the two Systems.
2½ %	$27.50	$1.00	$26.50
5 %	18.75	.50	18.25
10 %	6.87	.25	6.62
20 %	3.43	.12½	3.30

You can very easily see that the ratio in columns 2 and 3 is the same, but I want to draw your attention to column 4, showing the difference of cost per lamp in the two different systems under the conditions named. Suppose now that the cost of machinery, including boilers, pumps, engines, dynamos, house wiring and lamps in each case is about $15,000 for a 1,000 light plant. We would have to add in the three-wire system, figuring on 20 per cent. loss with full load:



$$1,000 \times \$3.43 = \$3,430.$$

In the alternating system we would have to add,

$$1,000 \times \$.12\tfrac{1}{2} = \$125.$$

But we will allow five times this amount in order to enable us to get a wire of very high insulation. This would make $625. In addition we should calculate $3,000 for transformers ($3 per lamp). This would make a total of $3,625.

It must be borne in mind, however, that a pole line, or underground conductors, for the three wire system would be much more expensive than for the alternating system, for obvious reasons. This would give us the following total result:

Total cost of 1,000 light three wire system, $18,430.

Total cost of 1,000 light transformer system, $18,625.

This would show the three-wire plant $195 cheaper than the alternating plant.

But now let us make some calculations on 2½ per cent. loss in the feeders; and we find that the feeders for the three-wire system would cost

$$1,000 \times \$27.50 = \$27,500,$$

and for the transformer plant:

$5,000 (again allowing five times the cost of copper for good insulation) and $3,000 for transformers, making,

Total cost of 1,000 light three-wire system, $42,500.

Total cost of 1,000 light transformer system, $23,000.

This would make the transformer system $19,500 cheaper than the three-wire system.

You can very easily see the trick in this calculation. Take a certain amount of money as cost for the entire plant, excluding copper feeders in both systems, and also excluding transformers in the alternating system; and assume a comparatively high loss in feeders; the difference in cost for such feeders in the two systems will then appear as a small percentage of the total cost of the plant. Then assume a high efficiency of such conductors, say, only 2½ per cent. loss, and the cost of such feeders will be a very large per centage of the total cost of the plant. You see in column 4 of table No. 2 that though the ratio at different losses is the same, the difference in cost will appear very small when a large loss in the feeders is allowed.

This method of calculation is not electrical engineering, but is instead a calculation invented, and probably patented, by some selling agent, who worked on commission. You can very easily see that if you want to sell a low voltage system, a high loss must be assumed, but if you want to sell a high tension transformer system, a small loss in feeders is permissible and competitive with the low voltage copper mine system. Thus you can make the total cost of the low voltage plant appear smaller or greater than the total cost of the alternating plant, as occasion may require. I very reluctantly make public this trick of the trade, but there is no charge for it to those gentlemen who should not have known it.

Now the question, of course, could be raised, why not figure on a higher percentage of loss in the feeders and still get the good results as shown in the first paper. I simply say this: Assuming a high loss in copper feeders is poor electrical engineering; it is a permanent waste of power; it requires complicated apparatus and permanent attention to keep the pressure alike in the different feeders with varying loads; it will cause greater lamp breakage, as necessarily even in the best laid out system, the potential will very often rise in some of the branches far above the normal; it necessarily must be quite a complicated task of electrical engineering to get all the conditions right for best results. On the other hand, with a small loss and a nearly constant pressure kept at the main distributing point, all these difficulties disappear. The electrical engineering part becomes very simple, and lamps can be attached almost anywhere to the line without throwing the system out of balance. Simply the impossibility of advocates of the low tension three-wire system inducing capitalists to spend money enough for such large conductors, as a small loss in the feeders would require, prohibits them from acknowledging all these advantages; and they necessarily must claim that it is good economy to lose more energy in the wires.

You can very easily see that the average load and loss question in table No. 1 of the first paper was simply introduced in order to make the loss appear smaller than it really is. Now I think I can save a good many arguments by simply giving you some information concerning the wires running out of the central station of a three-wire low tension plant in Minnesota. The first pole near the station carries all the outgoing wires; there are 54, varying in size from No. 0000 wire to No. 6. About one-half of the wires are No. 0000, and the remainder vary from 0 to 6. Lamps of various candle-power are put up, whose equivalent amounts to about 7,500 10-c. p. lamps. The average number of lamps burning during the day amounts to 2,000, while the average number in use during lighting hours is about 7,200. The loss in these feeders amounts, with full load, to about 20 per cent.; in one circuit it is even more. The claims, as far as economy is concerned, are 10 10-c. p. lamps per horse-power, including the loss in the conductors. The station is equipped with 10 dynamos, five engines and boilers for about 1,000 h. p. There are 14 employés connected with the station. The coal consumption for 24 hours, is about 53,000 pounds.

Now Gentlemen, taking these data, do you think that the theoretical tables and curves we had explained in the first paper were known to the gentlemen who laid out this station? The fact of the matter is that such a station can neither be economical nor on a paying basis. It can be only the laughing stock of electrical engineers except those who own some stock in the concern.

A 2,000-volt alternating system would, of course, show up far better than a 1,000-volt system, as far as first cost and economy is concerned. Even granting that the efficiency of an alternating dynamo is not quite as good as that of the continuous current dynamo, and that a small percentage of loss will occur in the transformers, what are these in comparison with the enormous loss in the feeders of a three-wire system, and the necessity of all

the complicating balancing devices at the station necessary in that system?

There is one point, however, which has not been touched upon, and that is that the whole calculation made in the first paper, was based upon the fact that the number of lamps fed by different feeders was at all times reduced in the same proportion. I know from practical experience that in most plants, this is hardly ever the case, and that resistance must be introduced to equalize the varying losses in the different feeders. This not only means waste of power continuously, but it also means wages of employés to watch the necessary instruments continuously, and to keep the different feeders balanced. So much for economy and efficiency. Of course, I do not want to repeat all the points covered in the paper read by Mr. Slattery nor by the latest communications to the electrical journals made by advocates of the alternating system against the three-wire system as expounded by Mr. Leonard.

As far as depreciation is concerned, let me again draw your attention to the Minnesota three-wire station and let me simply ask the question, would you rather repair transformers, or would you prefer to keep a pole line covered with a network of naked wires in repair? Suppose customers did not renew their contracts for lighting; which would be cheaper, to take a transformer and place it somewhere else, or have a high priced electrical engineer sit down and calculate how to balance that line again and take a couple of hundred lights from one place and transfer them to another point on the circuit. These points I think naturally apply to the chapter headed "depreciation."

I grant that well insulated wire will depreciate more rapidly than bare copper wire; but for my part I would prefer to keep six well insulated wires in repair, than a pole line with 54 naked wires as here illustrated.

Whether the depreciation of a high tension dynamo, is greater than that of a low tension dynamo, is a question that can only be answered after more experience than we have had up to this time.

Thirdly—Reliability.—I can see scarcely anything in the corresponding chapter of the first paper which still needs answering. I certainly can not see that for the reasons given, a continuous current system is any more reliable than a transformer system. Again let me draw your attention to the picture. I think that in the network of wires represented, troubles are more likely to occur than in six well insulated wires. Practical experience so far has not shown that the alternating transformer system is not as reliable in operation as the low tension continuous current system.

That a switch-board in an alternating central station plant should be more expensive than a switch-board and the necessary apparatus to run a three-wire plant, is something very surprising to me. I think that from what I have seen of the two systems, that the traps used in a three-wire station plant cost at least five times as much as those used in an alternating plant. What our contemporaries in Europe think of the reliability of the two systems, will best be illustrated by the following examples:

First—Milan, Italy, had a low tension direct current 10,000 light station. To reach a theatre 6,500 feet off, they added a Zipernowski-Deri 1,800-volt alternating transformer system, using underground cables.

Second—Dijon, France. This town had a low tension direct current central station, located in the centre of the town. The city council regarded the noise of steam engines, smoke, etc., in the heart of the city, a public nuisance, and compelled the local company to go to the outskirts. The company abandoned the whole continuous system and replaced it by a Zipernowski-Deri 1,800-volt alternating transformer system.

Third—Rome, Italy. A large central station is being erected and is partly finished—all done on the Zipernowski-Deri 1,800-volt alternating transformer plan, with a capacity of about 18,000 lights at distances of 10,000 to 16,000 feet.

Where, gentlemen, is the low tension plant reaching customers at such distances? I could go on in this way *ad infinitum*, but I think these few examples will suffice.

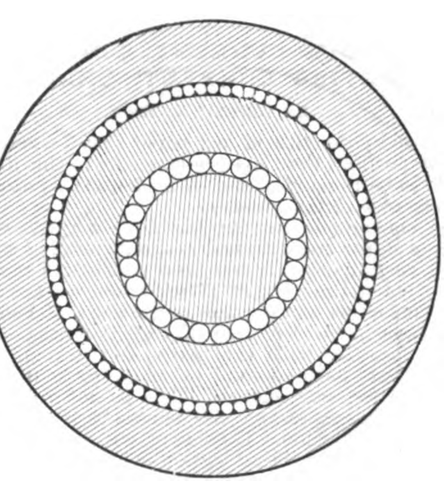
Fourthly—Variety and value of the possible sources of revenue.—The question of increasing the income from the central station by renting out power has been ventilated before, and it has been shown that it is not by any means impossible to run motors on the alternating transformer system. It has been found furthermore that in practice it is advisable to run a separate circuit for the distribution of power. There is no objection to using continuous current dynamos for this purpose. It could be said that extra dynamo capacity would be necessary in such cases, but I hardly think this is true. It certainly can not be expected that the same dynamo will run day and night in succession without ever stopping. I think that a certain reserve is necessary in any event. In the central stations I have seen only a part of the dynamo capacity is used during the day and the whole during the main lighting hours in the evening, leaving no reserve whatever. If these same dynamos should be loaded, running motors all day, there would be, in my opinion, a continuous strain put on the apparatus, which is certainly not advisable.

I quote from the first paper the following: "Then there is an almost unlimited number of applications of a continuous current on a small scale for such purposes as fire alarms, burglar alarms, distribution of time, annunciators, tickers, electro-plating, telegraph lines and telephones, all of which rely upon a continuous current."

Now I would like to have somebody tell me from what central stations such applications have been made on a large scale and on a paying basis. I do not know of any, and I think no central station would like to be troubled with these infernal little nuisances. The amount of money which could be gotten as revenue for furnishing current to these appliances would certainly not compensate for the trouble they would continually cause. Therefore I must say that I cannot see that the alternating system is any more dependent for its revenue upon the sale of light alone than a continuous current system.

Fifthly—Safety to Life.—The danger to human life from high tension alternating currents is always held up as a bugbear by the advocates of the low tension continuous system. In the first paper it was stated that it has been conclusively proven in practice that a 1,000-volt alternating current is fatal to human life and will kill a horse. I do not know of any experiments made in that direction, but it would certainly be interesting to know how much larger an animal than a horse could be killed by a 2,000-volt alternating current. A telephone operator at Pittsburgh, who was killed dead (by the first paper) with a high tension current, while handling the switch-board at the telephone exchange, has come to life again, in a communication to the *Western Electrician*. Maybe the same will happen yet with the horse. The fact of the matter is that at least 90 cases out of 100 where persons have been killed by the high tension current, death has been caused by the extra current set up in the field of a series dynamo when the external circuit was broken by the victim. Now, gentlemen, this danger does not exist in any alternating system.

The field of the alternating dynamo is separately excited, and such a powerful extra current cannot be set up and discharged



through the body of the careless workman even in case he should break the external circuit. I therefore claim that the main cause for *fatal* accident does not exist in the alternating high tension system. There is another danger which I think is greater in the continuous current system than in the alternating high tension system. Just look at that picture hanging before you again, and imagine a workman in that network of wires short-circuiting two of those heavy copper conductors by some means. The result would be a pound or so of molten and fused metal which would not only inflict very severe wounds but might even prove fatal. Quite a number of cases have come to my knowledge where persons have lost their eyesight or got otherwise mutilated by such accidents. You must remember that the wires of a low tension system are mostly bare while the wires of the high tension alternating system are well insulated. It may be asked why, in the case mentioned, the safety strips would not prevent such an accident. I will say that heavy fusible plugs melt rather slowly and would not break the circuit in time to prevent the accident. The smaller safety strips of the high tension alternating system carrying only a few amperes would respond a good deal quicker, though, as mentioned before, such an accident is less liable to happen in this system.

Sixthly—Effect upon existing property.—Why a low tension continuous system should be better protected by safety strips than a high tension alternating system is a conundrum to me, and I refer to the discussion of this matter following the reading of Mr. Warner's paper. The inductive influence which might cause trouble to telegraph and telephone lines can be just as easily avoided in a transformer as in a low tension direct current system. For underground work, I think a cable, as represented in the accompanying figure, would prevent all such troubles and would

furthermore prevent the retardation of the alternating system, as explained in a brief article of mine published in the *Electrical Review*, September 3, 1887. It may be mentioned here that wires carrying an alternating current are not in danger, from electrolysis, and that the wires keep cleaner if fastened underneath ceilings or on walls. Wires carrying continuous currents will very soon show a layer of dust and dirt which will appear as a demonstration of the magnetic whirls surrounding the wires.

In conclusion, I will give a *resumé* of the advantages of the alternating transformer system, as used for station lighting, in comparison with the three-wire system of distribution.

ADVANTAGES.

1. Location of central station plant need not be in the expensive centre of the city, but cheap real estate and power miles off can be utilized, thus decreasing the cost materially.
2. All customers near and far may be reached on a paying basis.
3. The price of conductors for feeders and mains is reduced to a minimum.
4. These wires being very small, the cost for poles and erecting lines or of underground work is materially reduced.
5. It does not take any great electrical engineering skill or complicated calculations to lay out such a system and make any alterations which may be necessary in the course of time.
6. The system is very simple, requires comparatively few stationary appliances and fewer employés for regular running and repairs.
7. The small loss in the feeders will result in greater efficiency, more lamps to the horse-power, smaller engines will be employed, less fuel consumed, and the earning capacity of the whole plant will be greatly increased.
8. It is easier to keep the electrical pressure constant thus burning the lamps at all times at even candle power and lengthening their average life.

THE CONTINUOUS CURRENT, LIMITED, vs. THE ALTERNATING CURRENT, UNLIMITED.[1]

BY GEORGE CUTTER.

YOU will see by the title of my paper that I assume rather a more positive position than my predecessors in this discussion. I do not claim to be impartial, and then produce arguments wholly tending to one side of the question.

That the continuous current has done a great work in the distribution of lights from central stations, none of us will deny, and, that in certain cases it has been successful in spite of the limitations of such a method of distribution, we are also pleased to admit. The effort among the originators of central station systems has been in the direction of high potential. We are all more or less familiar with the many and various devices and methods that have been adopted to enable us to use high potentials in distributing our energy. This is not only the case in electrical work, but it is also the tendency in other classes of central station distribution. Outside of our own especial department, one of the most striking instances is the high pressure hot water system of distributing heat in Boston. The statement of the chief engineer of this enterprise seems to me quite appropriate to our work, in that he considers "the distribution of heat a transportation problem." We can also consider the question of distributing electricity a "transportation problem," and the question is, the cheapest method of transporting the energy we sell. The cost of installation for doing this should, of course, be as light as possible in proportion to the work accomplished.

In the discussion which followed the reading of the last paper before the club, I maintained a position somewhat different from the other participants in the discussion, and immediately decided upon the title of the paper that I rashly offered to prepare, viz: "Continuous Current, Limited, *vs.* The Alternating Current, Unlimited," because I wished to emphasize the arguments offered at that time. I do not wish to close the door on the continuous current, nor on any department of electrical work whatsoever, as I wish for the greatest work possible with electricity, and stand ready to rejoice at the success of any method, be it with continuous current or without. I think such a position should be made very prominent as it contrasts so forcibly with the spirit of the first paper. I wish merely to show that in the present stage of our industry, the alternating current has decidedly the best outlook.

Shortly after the reading of the first paper I prepared a picture of the pole line in front of a station of an Edison three-wire system in New England, with which I was quite familiar, and then also planned the necessary pole line for the same number of lights on the converter system. In the discussion which followed the reading of Mr. Slattery's paper, I mentioned this point, of the relative appearance of the wire work of the two systems, to show that the relative depreciation was not simply that between pure copper and transformers.

As Professor Badt produced a very pretty picture of the three-wire system in Minnesota, I simply reproduce the same picture, with exception of the poles and wires. (We omit the pictures referred to here, as too large for our space. They are given in the *Western Electrician*, April 28 and May 12.) Here I have represented the necessary wires for 7,500, 10 c. p. lamps on the converter system. Not knowing the distance to the lamps that produced such a net-work of wires as was pictured in Professor Badt's illustration, I adopted the greatest distance which Mr. Leonard knew of an Edison feeder, viz.: 6,000 feet. I then calculated on the basis of one-half the number of lamps at 3,000 feet, and one-half 6,000 feet away, which you will readily perceive would be an exceptionally difficult condition for the continuous current to fulfill. For this work I have 10 wires in place of the 54 as pictured for the three-wire system, and in place of a good many more than 54, as would be necessary if the lamps were distributed as I have figured, and the wiring was done on the three-wire system. Moreover, my figures are for 2½ per cent. drop, whereas the three-wire system is on a drop of 20 per cent., giving a good margin for any difference in efficiency in the apparatus. Mr. Bliss made the remark "that the plan selected by Professor Badt was an exceptionally severe one for the three-wire system, inasmuch as all the wires went out in the same direction." I look upon it as a fair representation of the wiring for this number of lamps on the three-wire system, with the exception of having so many of them on the same poles. The difference would simply be, having more poles and more routes.

By leaving out some of the factors of the installation, it is easy to maintain by figures most any position we wish. This is the method adopted by some business men, and it is also the method in the first paper. No account whatsoever, was taken of the construction of the plant, or of the cost of poles, etc., which make up part of the installation, and which all tend to increase the cost of the three-wire system much more rapidly than that of the alternating converter system.

Mr. Leonard figures the cost of copper for the feeders of the three-wire system, and the copper and the converters in the converter system, and draws a very pretty diagram to show how far he can go with a continuous current three-wire system for the same money as with the converter system. The very best answer, to my mind, to these figures, is to have Mr. Leonard's customers ask him to put in the installation at the prices he gives. We will, in such a case, give him the advantage of the difference in price of copper.

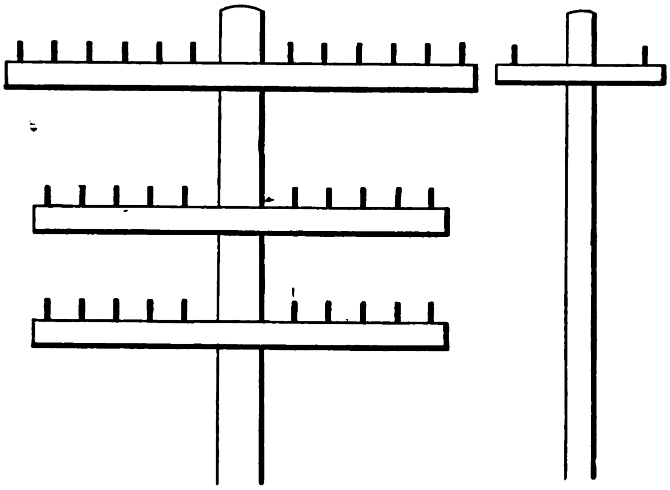
One feature of this figuring is something I do not quite understand; for instance, in table No. 3 of H. Ward Leonard's paper, it is stated, "that with 30 volts maximum loss, the cost of copper per lamp for the three-wire system at 6,000 feet, would be $3.87. Then, in his analysis of this table, he calls this 6,000 feet "the average feeder length," and says this is equal to a circular area of 18,000 feet, or 3½ miles. How many times I have wished that the cost of copper for distributing our lamps was as elastic as this implies. Now, a radius of 18,000 feet circle is 9,000 feet. Mr. Leonard figures 800 feet between feeder terminals for his mains, and 100 feet from the mains to the lamps. We will suppose that half this distance between feeder terminals, 400 feet, and the 100 feet for the service wires, are in a direct line with the feeder itself, thus making the feeder 6,500 feet. I would like to understand how the cost of wires for a lamp 6,500 feet away can be the same with the same system as for 9,000 feet away. The relative cost of the wire under such circumstances being as the squares of the distances, I make it out that the wire work for 9,000 feet costs about double that for 6,500 feet.

The continuous current advocates, try to scare away the alternating current with the cry of "danger." To attempt this at the present day, in face of the large amount of good work that has been done with high tension currents is about like trying to mop out the ocean with a kitchen mop. The people who raise the cry, with few exceptions, do it for a check on the alternating current, not because they fear the danger they portray. If the danger is such as to preclude the high tension system, we might as well stop at that point and not bother to figure on the cost, depreciation, etc., of high tension plants. Their remarks, and the practices of the companies some of them represent, show that neither of them fear this danger. They are kind enough to say they think the converter system might be used as an adjunct to the continuous current plant to reach outlying districts beyond the limits of their favorite, but limited system. If the alternating current is such a dangerous fellow, as they try to prove, why should they advocate its use for outlying points, especially, when such points would consist largely of residences? I must ask them if they would distribute lamps around the family hearth for servants and children to handle, with a system that is too dangerous to use in stores and offices? The converter was developed on purpose to enable us to reach customers at a distance, and still have the E. M. F. at the lamps reduced to a harmless quantity. By systems of installations already in use, the secondaries can all be made absolutely safe. The danger then is reduced to the primary wires.

1. Read before the Chicago Electric Club, May 7, 1888. The fifth of a series of papers upon the subject, "The Continuous Current *vs.* The Alternating Current," before the club.

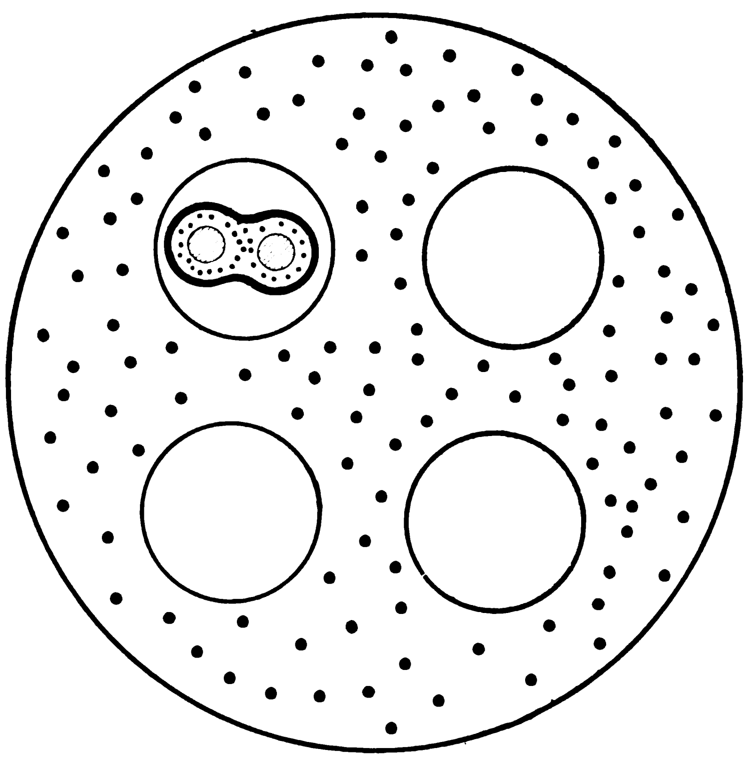
Dynamos of 1,200 volts are run on three-wire systems. I must therefore ask a direct question. Is a 2,400 volt system of distribution continuous current, less dangerous than 1,000 volts alternating? If the tension of 1,000 volts is dangerous why install and advocate systems of 2,400 volts?

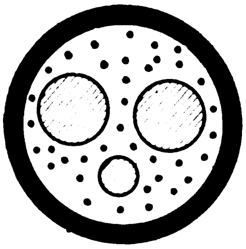
I feel that I must raise another point to show that fear of high tension is assumed for business policy, and not philanthropy. Suppose we do not adopt the policy of grounding the secondary,



and some transformer leaks. The individual secondary is thereby subjected to the same tension to ground as the primary, provided, of course, that the other ground comes on the opposite primary wire. On this secondary circuit may be but few lamps that people could handle. This is probable. Therefore the danger of such a leak only exists in a few lamps.

Mr. Leonard says, the best method of distributing the electric energy from a distant point is with the motor generator. Two





1,200 volt dynamos to be connected in series and the circuit carried to the upper story of some building where the motor generators are placed. From this upper story the regular three-wire low tension system is distributed. Leave out the item of cost of the secondary system, and its limitations, but consider now the danger. If any one motor generator of the whole lot should leak, there would then be the danger of the 2,400 volt tension throughout the whole network. I quote Mr. Leonard, "The motor generator for this work is ready for the market, but it has been learned the cost per lamp can be very materially reduced by increasing the speed."

The alternate current converter is, as Mr. Kennedy well said, "The simplest piece of apparatus imaginable," and it has no moving parts whatever, no increase of speed; therefore the relative danger of leakage between the two converters is almost as one to infinity, in favor of the alternator. And still the leak in the alternate converter endangers a few lamps only, whereas the leak in the motor generator endangers the whole network. Here is a company with able representatives facing their almighty dollar, and advocating a system in which a leak would give 2,400 volts throughout a network of wires, and then facing somebody else's dollar and crying "danger" against a system in which a leak gives 1,000 volts to a few lamps, and even that danger can be eliminated.

When Faraday was showing some experiments illustrating his great discoveries, and showed how simple it was to produce the electric spark with his apparatus, the dean said, "He was sorry for it, as it put new power into the hands of the incendiary."

Gentlemen, when any new devices are put forth to the world, there are always people who cry them down for one reason or another and generally the cry of danger is raised, but our progress is not to be checked in any such manner. These considerations lead me to believe that our continuous current friends do not fear the danger, or consider it should hinder our progress beyond the limited field of the continuous current. And, as I believe the danger of distributing electric energy by high tension alternating converter currents to be much less than the danger with gas, locomotives, steamboats, crowded streets, with all sorts of teams, and drivers, in fact, most of the methods and practices in crowded centres, I think we can proceed with the consideration of cost, depreciation, and revenue, to learn if the scheme is strong commercially.

I have also made another sketch, illustrating in a certain extent, the difference in the pole line between the three-wire system and the converter system; the large pole representing the pole in front of the Edison three-wire plant in New England, which was figured for 1,000 13 c. p. lamps, the longest feeder in the system being 2,400 feet. My friend, who has charge of this installation, writes me that he is now using 980 16 c. p. lamps, and therefore has not sufficient potential at the lamps.

The company have decided to reconstruct the whole wire work this summer. There are about 10,000 lbs. of copper in the feeders and mains, and a nice little half ton more in the connections in the station. If the company were fortunate enough to buy this copper at the price quoted by Mr. Leonard they would have to pay about $1,600, provided they used bare wire, but in this instance they used underwriters' wire, which, of course, costs 25 or 30 per cent. more, owing to the extra weight.

Every installation of this sort requires a system of feeder regulators, which are a very expensive factor in the first cost. In this particular case these regulators cost about $1,200, which is 75 per cent. of the cost of copper for feeders and mains. Any comparison in the first cost between the two systems under consideration should include all these different items.

I also have pictured the necessary pole and wires for 1,000

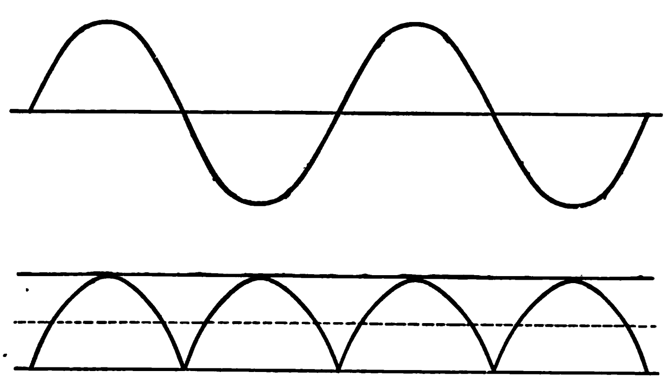
16 c. p. lamps, supposing they were all at a distance of 2,400 feet, which is much more severe than the three-wire installation pictured on the pole by the side of this one, and still you can all compare the difference. The alternating system requires no pressure wires because of the facility of making a voltmeter, which compensates for the variation in loads. As the alternator plant is operated with a very low percentage of drop, in this case I have figured on 2½ per cent The difficulties of regulating for change of load are very slight, and the apparatus for accomplishing this, very cheap. Moreover, wherever regulators are used for alternating currents, they consume little or no power in doing their work,—just the reverse of the continuous current regulators.

As a probable improvement in the incandescent lamp was mentioned, I would like to emphasize the fact that most makers of these lamps to-day are willing to guarantee about 25 per cent. better efficiency with the 50 volt lamp than with the 110 volt lamp, and the result of our experience in this direction thus far indicates quite decidedly that whatever improvement is made in the 110 or higher voltage lamp, will also give a proportional benefit in the 50 volt lamp. Briefly, then, the 50 volt lamp will probably always be 25 per cent. better than the 110 volt lamp. The importance of this difference in lamp efficiency is readily appreciated by all electrical engineers and by business men also, when they are able to sell 25 per cent. more energy with the same outlay for the plant.

The relation between dynamos and converters has been alluded to. This relation is only electrical, and not mechanical. Mechanical difficulties in a dynamo change the electrical relations very materially. How we wish that the mechanical conditions would allow us to run our armatures within about one-hundredth of an inch of our pole pieces.

As I expressed myself quite emphatically in relation to the relative reliability of the alternating and continuous current installations, I will not venture upon this point, the situation simply being that with equal engineering ability, the converter system can be made as reliable, yes, more reliable than the three-wire system, because of the greater flexibility in the converter system.

As to the relative depreciation in the two installations, I would like to call attention again to the two pictures of the station in Minnesota, and ask any practical man which he would prefer to



maintain for twenty years,—pole lines with a network of 50 wires, as shown for a three wire system, or a pole line with 14 wires for the converter system and the converters. Is this depreciation that between pure copper and the converters? And when we get to placing our circuits underground the relative depreciation will be decidedly in favor of the alternating system.

Mr. Lieb, the engineer in charge of the Milan station, has had considerable experience with the Edison tubes and Siemens cables, and also cables for 2,000 volt alternating system, and in a communication to an English periodical, he says:

"How closely allied the question of underground conductors is with the future of electric lighting from central stations needs no demonstration. The local engineers do not claim that this difficult problem has been completely solved in Milan; but what has been done in that direction thus far, makes it appear probable that no very serious difficulty will be met with in a general system of distribution of high tension currents by means of underground cables."

I have also made a picture of the underground conductors. full size, for 1,000 lamps on the three-wire system 6,000 feet away at 10 per cent. drop, and the same number of lamps on the converter system at 2½ per cent drop. If anything goes wrong with the large conductors and tubes, the street must be taken up for the repairs, whereas in the converter plant, the cables are drawn into conduits, as shown, which is the only proper method for underground distributions, and these wires can be withdrawn and new ones put in their places at comparatively small expense.

Just glance at that large plan and imagine the conditions under the surface of the street with all those tubes laying there like a gridiron barrier to any other work. The case shown is a mild one as compared with some places, where twenty odd tubes lay along a snug little strip twenty feet across.

The retardation caused by the iron in the neighborhood of the converter plant is of too slight a quantity to be considered at all in practice.

Early in my experience in making estimates for alternating plants, I wished to know whether I should make any allowance whatever for this retardation, and therefore, wrote to our people at Lynn for advice, as I knew they had experimented a great deal on this particular point. Their answer was, that I need make no allowance whatever, that in the installations they had made, they had never realized any loss from this cause. The figures certainly back up this assertion. A 40 light converter uses about 3⅓ h. p.

As Mr. Leonard quotes Bro. Kennedy as good authority on transformer work, I will quote him also, as he said distinctly that he "could use transformers with a loss of less than 2 per cent." My experience leads me to believe that this is correct, but I will take a loss of 5 per cent. mentioned by Mr. Leonard, which will give us a loss in a 40 light transformer of .16 h. p. running at full load. If empty, the loss would be much less than this. The primary wires for this converter have two amperes, passing at full loads through many convolutions placed very near the iron. As the loss in this transformer is electrical as well as magnetic (and probably largely electrical) the loss by retardation will be a small part of .16 h. p.

It is difficult to imagine a primary circuit of a 1,000-light converter plant to be so situated in relation to the iron in the neighborhood, as to use up the same energy by retardation as is used in a 40-light converter when empty, which shows pretty conclusively that the retardation from this cause is too small a factor to talk about.

This diagram is intended to represent the relative energy of the continuous and alternating currents. Drawing all the waves above our zero line then draw a line along the top of the waves for the 50 volt line. The areas of all the waves show the energy of the alternating current and the areas between the two straight lines that of the continuous current, provided the alternating current has the same voltage as the continuous current. In that case the actual energy is much less than the continuous current. As the carbon cools very slowly and the waves are very rapid, probably this is very near the actual condition.

The heat of a 16 c. p. lamp 52 volts may average less on alternating currents than on continuous currents, and still the illuminating power be practically the same to the eye because the impression left on the vision would be that of the greatest brilliancy with the rapid changes of the alternating current. This indicates that the actual energy in a 16 c. p. lamp is less on the alternating current than on the continuous current.

I have touched upon the various points of first cost, economy, reliability, safety to life, etc., in rather a mixed up fashion, and now I come to the most interesting part, and the most important part of the whole question, that is, "Variety and value of the possible sources of revenue."

In distributing our energy we wish that system which will enable us to accomplish the most, and which will be readily adaptable to the various demands. Some business men may adopt a system that can only be used in a limited area, and that at an enormous expense. It is barely possible that Mr. Bliss touched the keynote of this tendency on the part of some business men. We are all aware of the past relations of Mr. Bliss to the Edison company, and probably, therefore, he is more or less conversant with the business policy of this company. In the discussion at our last meeting, Mr. Bliss said, "The capital that is being furnished for those stations (referring to the large Edison stations in Chicago and New York) comes very largely from the same persons who made the first installation of a large incandescent plant that was put into the United States." Possibly, these capitalists have some other benefits from their investments than that arising from the actual income of the stations themselves. That has often struck me as a peculiar feature in the business of the Edison company, which company is mentioned because of the large amount of work it has done with continuous currents, and because they are about the only large concern that tried to close the door against the alternating current, viz: the capitalists who furnish the necessary funds for the largest Edison plants in different parts of the world, are interested in the sale of similar installations elsewhere; possibly they look to these sales for the reward of profit on these large central plants that have been put in at such an enormous expense.

As Mr. Bliss has promised a paper on the continuous side of this question, I certainly hope he will give us figures that will enable us to understand how the dividends can be paid by the actual earning capacity of large central stations of the continuous system, not only because I wish to know positively that these enterprises are a sure success, but also, for the benefit that such demonstrations will be to the alternating side of the question, because if that will pay which is so limited in its capabilities, we can certainly feel sure that another installation furnishing the same class of energy can pay still better by virtue of its greater flexibility and almost limitless possibilities.

In the discussion which followed the reading of Mr. Leonard's paper, this gentleman stated that the "cost of operating and maintenance of any system is certainly reduced if they can operate from one source of supply." Thus showing that he does not believe in various stations for supplying energy to a large city. The remark was made as applying to central stations, but it appears to me to apply also to accumulator stations, because they must be operated on low potential, therefore, there must be many of these accumulator stations, each one of which is of necessity equipped with many and varied devices for regulating the feeders, etc. That attempts are being made to run lights from accumulator stations, we are all well aware, and hope, of course, that they will prove a success, but that remains yet to be proven. When they are perfectly developed, and supplied with all the regulating devices above mentioned which appear to be necessary, the possibilities of profit may disappear, and I am free to admit I am afraid they will.

The idea of converting our energy seems to be the prevailing idea of to-day, and our electrical journals are filled with illustrations, paragraphs, figures, etc., about some sort of a converter system, alternating converter, continuous current converter, accumulator converter, each one trying to prove that his especial system of conversion is the best. This is interesting, as it shows pretty conclusively the general feeling that the continuous current of itself, is altogether too limited in its possibilities for the work that we have in hand all over the world to-day. Our industry is growing, and people are not satisfied with working within just such prescribed limits. Hence, the various devices that enable us to go beyond these limits,—and the alternating current seems to be just the thing wanted for the purpose, as it does its work in a manner not accomplished by any other converter system.

Admitting that the continuous current converter may be made quite a success, it still can never be placed about town in all sorts of situations, and of all sizes, as can the alternating current converter. It is a machine more or less difficult to keep in order, being, as Mr. Leonard says, "run at a high speed," that necessarily means constant watching. Therefore, these converters must be used in secondary stations with low tension system distributed from them. This is also the case with the accumulator. It also requires a great deal of attention, and if used for central station distribution, must be placed about town in secondary stations. As the network from each secondary station is low tension, we must still work on high percentage of loss, in order not to have too many stations, and this combination of low potential and high percentage of loss, means constant attention to the regulating devices, that is to say, every one of these secondary stations embraces more or less the difficulties of the present continuous current station. And, further still, the secondary network can give but a uniform electrical condition *theoretically*, therefore your continuous current, whether it is of the 3-wire system, multiple series system, continuous current converter system, or accumulator system, is limited, and very much so, in its possibilities. Any use of them at all, requires high engineering ability, and the very best of engineering ability can only accomplish a limited amount of work.

The alternating current is entirely a different sort of fellow; extremely flexible and unlimited. It enables us to start small and grow with the demands with but very little trouble in the calculations. The cost of the conductors being a very small part of the whole installation, it is easily determined what the installation will cost. Those of you who have made calculations for the continuous current plant, or have been called upon to furnish the necessary data for such a calculation, appreciate readily the difficulties involved, nearly all of which difficulties disappear the minute you commence to work with the alternating current. The change in the load of a considerable amount in one part or the other, it is readily taken care of by an ordinary man and at no very great expense. Possibly, a little work for the expressman to carry a few converter boxes from one customer who has given up lights to another who has taken some on. There is no great bother about maintaining proper potential. This current will also furnish almost any phases of electricity desired. Instead of having a couple of wires in our rooms which will furnish 110 volts and no more or no less, we have a couple of wires which will furnish any voltage, or most any quantity desired, so that if a new industry should arise where 8,000 or 10,000 volts are required, two little wires carrying the alternating current, will furnish the energy which can be converted to this potential. Or, if a very large quantity is desired of low potential, these same two wires will furnish it.

For the rental of lights alone the general impression has been, that the alternating current can do it satisfactorily.

The work of motors on the alternating current has been discussed sufficiently before the club, therefore we will await further developments in this direction. The alternate current motor is certainly further advanced to-day than was the continuous current motor when the work commenced with the continuous current distribution, so we will soon be able to rent power from our alternating network, provided it is found a matter of policy to do so from the electric lighting circuits.

There are other industries now before the world which certainly bid fair to become of great importance, and as one department has been pretty well developed, I will allude to that more particularly, and that is, the welding and manipulating of metals by electricity. I have been fortunate enough to secure a number of samples of metals welded in this way, showing that I am not dealing in "futures" when talking of this industry. There may be a large source of revenue to central stations that are providing alternating currents, in furnishing the energy for this class of work. As it may be said that the continuous current is also being used for the welding of metals, I must say that this method has not proven a success, having seen the operation in a large workshop in Paris, where they tried to make oil tanks by welding metals together with a voltaic arc; I know that the method is not at all a practical success as yet, as the metal is oxidized and destroyed, burnt up, so to speak, by the intense heat.

The continuous current can be used for electric welding, but as enormous quantities of current are required, the dynamo supplying the same must be near the work. This limits the continuous current very much for this class of work. Not so with the alternating current converter. We can attach to our two little wires a very small converter for jewelry work, or a very large converter for heavy welding.

Another feature of the question is this, it is easier to work the registering meter on the alternating current than on the continuous current. The difficulty in this class of meter lies in the fact that they must record in proportion to the number of lamps burning, or the amperes used, whereas the work done is, by itself, in proportion to the square of the amperes. This difficulty is quite easily met in the alternating current, by the use of a simple kicking coil, but it is not one easily met in the continuous current.

I have made a diagram (we omit the figure), illustrating the subject of my paper as a final summary of what I have tried to express. I think it shows pretty conclusively what my title implies, namely, the continuous current, limited, *vs.* the alternating current, unlimited. On the left I have pictured two large wires for carrying 1,000 amperes and 125 volts, which you will see equals 125,000 watts. Connected to these wires I have represented an accumulator, motor and an incandescent lamp. I do not mention time circuits, telephone or telegraph, as I do not consider them worth bothering with in an electric light station. These different factors are all necessarily 125 volts, not more or not less, simply limited to that phase. On the right of the drawing I have represented two small wires for 1,000 volts and 125 amperes, which is equal in energy, namely, 125,000 watts. The wires for this current are one-quarter the diameter of the others. I have represented, as connected to this circuit, one transformer, operating 52 volt lamps, one operating 110 volt lamps, one giving 20,000 volts, another giving 20,000 amperes for heavy welding, one giving 500 amperes for jewelry welding, and I have also Professor Thomson's method of charging the accumulators on alternating currents, and I have a motor. Here you see are two circuits side by side conveying the same energy, one of which gives us fixed E. M. F., and the other gives us almost any E. M. F. or quantity we wish. To carry the continuous current of such a quantity, 1,000 feet with a loss of ten per cent., we would need copper rods two inches in diameter, whereas, the other current can be carried at greater distances on a very small wire.

THE CONTINUOUS CURRENT vs. THE ALTERNATING CURRENT.[1]

BY GEORGE H. BLISS.

I MAY as well admit myself at the outset to be ignorant from personal experience in regard to the alternating current as applied to electric lighting, and confess to never having seen such a plant or station in operation. My early impressions of the alternating system from personal and published statements were very favorable, and I was highly gratified that a practicable method had probably been discovered for the economical distribution of electrical energy over greatly extended areas. There was something quite pleasant in contemplating this development. This country had given to the world a practical method of electric incandescent lighting, and it seemed only fair reciprocity for Europe to return the compliment by an alternating system which should greatly enlarge the sphere of the electric light industry. In looking forward to this discussion, which was to be largely educational to me, I anticipated that the friends of the able imitators of the alternating system who have made such substantial progress with its introduction in this country, would bring forward conclusive arguments for its general adoption. I have been disappointed in this respect, and there is a growing conviction in my mind that the compressed air, which made the monied foundation for much of the support of the alternating current, has in some way or other found vent in altogether too

1. Read before the Chicago Electric Club, June 4, 1888. The seventh of a series of papers upon the subject, "The Continuous *vs.* The Alternating Current," before the club.

windy and extravagant claims for that method of electrical distribution. No doubt the intimation will be repeated that I am closely allied to the parties controlling the leading constant current system of incandescent lighting, but such is not the fact. I am not connected nor in any way authorized to speak for that system. The representatives of that interest who are members of this club are quite able to do that for themselves. I am indeed prejudiced in favor of the Edison system, but am not unwilling to give credit and recognize the very valuable work done by the other inventors. It is hard, however, for me to forget that portion of the history of incandescent lighting with which I was closely identified.

I well remember when there was no incandescent electric light used in the United States. When Mr. Edison had satisfied himself that the (so called) subdivision of the electric light was economically and commercially possible, his public announcement was greeted with derision by high authorities in this and foreign countries. In the light of subsequent developments most of these gentlemen generously acknowledged their error. In like manner, I shall claim the privilege of stepping off the track, if the locomotive represented by the alternating current shall threaten to run me down. The unanimity with which the arc light companies first derided and subsequently grabbed for the incandescent business always refreshed me as a striking illustration of the prevalence of electrical "cheek." The avidity with which they are now rushing to the alternating current makes me fear that their experience with the constant current has not been sufficiently profitable to satisfy their vaulting ambition.

Early in the development of the Edison light I had the exquisite pleasure of attending Professor Morton's famous lecture to the members of the national gas convention at the Stevens institute, in which he so ridiculed Edison's proposed division of the electric light that his audience was overcome with the utmost hilarity. The gas interest has since that date had abundant cause for reconsideration, and at last, aided by hard knocks and inherent practical business sense, has come to the conclusion, in many instances, that the electric light is a good thing, which they will own themselves. I pioneered the incandescent electric light in Chicago, although closely followed by my friend, Mr. Warren, who has since always been able to keep anyone from feeling lonely in the business, and it is no small gratification to me that some of the men who were most violent in opposition to the incandescent light have since fitted up their buildings with it, and even made large investments in electric lighting enterprises. Having actively participated for four years in the early introduction of the Edison constant current system of incandescent lighting, and being somewhat familiar with its steady and successful subsequent progress, I am not prepared to rashly follow the lead of others into the alternating system until certain that it will not lead to disaster. We have had these bursts of enthusiasm in the business before, of which the premature efforts at the introduction of storage batteries are a striking illustration. I believe in proving all things and holding fast to that which is good, rather than rashly take up what in comparison can only be shown to have a promise of success. Now let us see if we can find a few shreds left upon which to hang our belief that the constant current system of electric distribution is still entitled to preference as against our mortal enemies who seek to overwhelm us with the alternating method.

Not having even attempted to figure a system of electrical conductors for nearly three years, and my attention having since been largely turned in other directions, I shall not attempt, after the able expositions of the learned and more experienced members of the club, who have preceded me, to treat the subject from a scientific standpoint with fancy diagrams by way of illustrations. I shall be compelled to confine my attention largely to the commercial side of the question, but as Mr. Edison has often said, "Any invention which is not commercial is N. G.," and as we claim the constant current system is commercial, in that it now returns a profit to the investor where ordinary good judgment, practical skill and management is employed, something may still be found worthy of consideration from my point of outlook. Considerable has been said in the progress of this discussion upon the subject of electrical engineering ability.

In the electric field I know of no undertaking more brilliant in conception, audacious in execution and successful in operation than the first district station of the Edison Illuminating Co., in New York city. At the time it was planned electric incandescent lighting was generally believed to be impracticable. The lamp, dynamo, underground conductors, meters, regulating apparatus and various appliances had to be perfected and to a large extent devised. This constant current low tension system was installed in the financial centre of this country in the teeth of the most powerful gas companies in the land, and in a district where the buildings are largely vacated at night, so that the amount of light required is relatively small. The light was to be sold by meter, and had to win its way not only in competition with gas, but with other forms of electric lighting. Croakers prophesied that the system would not work; when it did work that it would not endure, and when it endured that it would never pay. It will be five years in next September since current was first turned on the system, and with the exception of two hours on a single occasion when the safety catches in the feeders burned out from insufficient capacity, there has not been a single instant, night or day, when the current supply has failed. When some of the alternating current stations with their dynamos and single pairs of conductors have made a record equal to this, the capital invested may begin to feel secure, for constancy is a prime factor in electric lighting. The means employed for regulating the light have been found reliable and satisfactory. Not the least interesting feature in connection with the operation of this system to me is the means employed to locate faults in the underground conductors by tests at the station while current is flowing over them. It is not unusual to locate from the station within a few feet of the spot where the fault exists. Although the Edison tubes in use are the first manufactured, they have proved reliable in the main and are in good condition. The meters give correct measurement of the current used, and customers pay their bills. 11,000 16 c. p. lamps are daily supplied from this station. Although this is the first large incandescent system ever put into operation, and although the installation was made on the two-wire 110 volt multiple method at a cost certainly double and perhaps treble what it could be duplicated for to-day, the investment is profitable. This success has resulted in the capital being furnished largely by the original investors for the four Edison stations now being installed in New York with an aggregate capacity of 150,000 lamps. A gentleman of large electrical and business experience, who recently rigidly examined the books of the Edison first district in New York with the view of a considerable investment of his money in the Chicago Edison station, which investment he decided to make, assures me that the station is earning 8 per cent. upon its capitalization. It is interesting to note that the Chicago Edison station which is now being erected here will have capacity for 50,000 lights instead of 30,000, as originally intended. The money furnished for this work comes largely from parties who have been interested in the Edison business in the west for several years past. The large Edison stations in Boston, Philadelphia and elsewhere ought to convince any fair-minded man that profit is to be realized in the use of a constant current low tension system. Capitalists as a class do not transact business on a sentimental basis, and if our alternating friends shall be so fortunate as to scoop the present investors in the constant current system by a competitive system, we need not waste much time in sympathy and lamentation. We, as members of the dear public, may get some benefit in the price at which light can be had. My only suggestion is that our alternating friends hurry up, for operations in the Edison constant current system are in early contemplation, which, for the amount of capital involved, rivals the Chicago gas trust syndicate. An established electric light industry is a hard thing to unseat, and time, experience and readiness for operations are valuable elements toward early success. I consider it conclusively demonstrated beyond cavil or dispute that capital invested in Edison constant current installations in large areas of compactly built cities under the most adverse circumstances in the present state of the art will form a profitable investment.

As the opinion prevails to a considerable extent that the alternating system presents peculiar advantages for small towns or cities with a scattered population, I will cite only one instance in favor of the continuous current 3-wire Edison system. The city of Laramie, W. T., has a population of 6,000 people, and fairly represents the average place of that size. There is now in operation at that place an Edison station supplying 4,000 lamps. A personal friend who invested some money in this station largely upon my advice, informed me that it is paying him 10 per cent. This earning has been made until recently exclusively from the sale of current for incandescent lighting, the station being a little over two years old. Early in the present year the sale of current for use in supplying power was commenced, and the prospect is that within the present year the income from this source will equal if not exceed the income from light. I will instance one or two customers to whom current for power is sold. The Laramie Milling company is supplied with current for two 25 h. p. Sprague motors. It is a modern roller mill with the capacity of 100 barrels of flour per day. There is no boiler or engine about the institution. For reasons connected with the manufacture it was decided to use two 25 h. p. motors instead of one of 50 h. p. The manager of the mill says the power is satisfactory in every way, and as constant as the best regulated automatic engine. He enumerates the following advantages: Ease in placing the power where wanted, and thus avoiding long lines of the shafting or more objectionable belts; economy of room for power plant; saving of first cost of power plant, interest and taxes; 30 per cent. saving in insurance rates; an economy and increased reliability over steam power for his use. It may be unfair to the Edison interest to give away to our alternating current friends the price which is paid for the power, but in this case I am going to risk it. The average load on these two motors is 23,000 watts, and the price paid is $292 per month of 26 days, ten hours per day.

The Laramie Edison company also supplies current to a rolling

mill for a 20 h. p. Sprague motor. Power is communicated from the motor to 120 feet of three-inch shafting. This shaft drives four spike machines, two bolt headers, two nut pressers and a large number of threading and tapping machines, including some emery heads. The average load is 11,250 watts for twenty hours a day, which is paid for at the rate of fifty cents per hour. The mill was formerly run by steam power at a larger cost, and in not nearly as satisfactory a manner. These mills are supplied with current directly from the regular feeders of theEdison station. In addition, the Laramie company is selling current for a number of smaller motors. Already the income of the company is at the rate of over $6,000 a year from the sale of power. These statements are made upon the authority of R. M. Jones, the manager of the Laramie Edison company. This illustration furnishes conclusive proof that the Edison constant current, 3-wire 220 volt system in cities of the smaller class, can be made profitable.

It is appropriate at this point to give the question of the sale of current for power from electric generating stations additional consideration. This branch of the business has already acquired magnitude, and is destined to grow into gigantic proportions. The maximum lighting load of a station is seldom carried for more than from two to three hours in the twenty-four. During the remainder of the day there is a large surplus capacity in boilers, engines, dynamos and conductors, which must remain idle unless employed otherwise than in supplying current for light. The sale of current for power comes in to fill this gap as it is needed largely at a time when light is not required. The sale of a single electrical horse-power of energy for ten hours is equivalent to the sale of 48 16-candle lamps for three hours, which would be a large average burning. It is a fact where the Edison stations are run day and night that the current sold for power exceeds the current sold for day lighting. and in many cases it is rapidly growing toward an equality with the entire sale of current for light night and day. I will give one example of what an Edison station can do in a city of the medium class.

The Detroit Edison station is now supplying current for about 9,000 lamps, and they are behind their orders for installations to the extent of several hundred more. In regard to the sale of current for power it is supplied as follows: Printers 6, newspapers 1, opticians 1, laundry 1, chemical works 2, wire works 1, shoe manufacturers 3, bookbinders 1, machine shops 2, telephone companies 1, knitting works 1, hydraulic elevators 3, elevators 3, sewing machine shops 5, dentists 6, jewelers 3, ice cream dealers 1, sporting goods 1, ash elevators 1, storage boilers 1, also quite a large number of small motors for single fans, sewing machines, etc. The party taking the largest amount is the Detroit *Tribune*, 30 h. p., and the knitting works take 15. The present aggregate sale amounts to 162 ½ h. p., which at $100 per year makes an income of $16,250, which is not to be despised. In view of such a source of revenue which is available to the constant current system, I cannot avoid the conviction that the capitalists should use extreme caution in investing his money in alternating systems which so far are only able to promise a successful motor for use in connection with their current in the dim hereafter.

A great hullabaloo has been made in this discussion about the cost of copper in connection with the constant current system. In the territory which it is the custom to attempt to cover with the Edison system the cost of copper seldom equals 20 per cent. of the entire cost of the installation. As the constant current has unrivaled capacity for producing revenue within the territory covered, it certainly ought to be greatly preferred even if there was a large margin of cost in copper against it. I will give one or two examples of what the actual cost is for copper in a couple of Edison stations now in process of installation. For one installation which provides 100 street lamps scattered over an area of 1½ miles square and 500 lights for stores, residences and churches in a mile square, the entire cost of copper at 20 cents per pound is $3,000 or $5 per lamp. For another installation where 100 street lamps are scattered in one area two miles square and 800 inside lights in an area about a mile square the entire cost of copper at 20 cents a pound is $3,102, or $3.44 per lamp.

I have not as yet seen or heard a satisfactory answer to Mr. Leonard's statement of the comparative cost of the conductors of the two systems when converters at $3 per lamp are taken into consideration for average practical installations at reasonable distances. As Mr. Leonard has already stated, the load diagrams of the Edison stations show that the maximum number of lights burning at one time is only 40 per cent. of the number of lamps actually installed. I want to emphathsize the point that conducting capacity in the feeders and mains is only supplied for the highest number of lamps carried at one time, and yet in any one building all the lights may be in service at once. Therefore, conductors must be supplied for the full lamp capacity. On a general Edison installation with conductors for, say, 1,000 lights, 2,250 lamps may be installed in the buildings. The investment for converters from this standpoint is enormous. Parties engaging in the electric lighting business presumably do so with a view to doing the great bulk of the lighting in the territory covered. I do not suppose over ten per cent. of the gas jets in Chicago are ever lighted at one time. The party undertaking to supply converter capacity for a number of lamps equivalent to the gas jets in Chicago will have an investment on his hands sufficient to appall any one who is not swayed by an imaginary advantage.

Criticism has been made upon the constant current station on account of the amount of apparatus it contains. For my own part I greatly prefer apparatus located at a central point, in the hands of competent employés to keep it in order, to scattering a lot of converters all over creation where they will necessarily make a great of trouble. Any one who has had experience with electric appliances in which insulated wire is used and through which powerful currents pass, whether it be telegraphic, fire alarm, electric light, or any other form of apparatus, knows that it is liable to frequent troubles, and when converters are placed on poles or the exterior of houses, or even in the interior of houses where they necessarily must often go in damp places, the claim that they will not need frequent care and attention is certainly all bosh. Moreover, in many of the latest Edison stations feeder equalizers are dispensed with altogether, so that switches, ampere and pressure indicators constitute the sum total of the special appliances.

It is just as easy to run constant current generators with a separate exciter for the fields as is the case in the alternating system, so I fail to see any special force to that argument except that it is not usually done. The advantages to my mind of being able to multiple-arc dynamos, and of having a number of feeders supplying a common system of distributing main conductors is very great. The auxiliary conductors used in connection with the alternating system bring up the cost for copper in a measure, and add to the complication of their circuits. The objection which has been urged to the operation of two classes of apparatus in the same station will hardly hold so long as our alternating friends find it necessary to use constant current dynamos to supply the arc lights operated from their stations. I am still unable to see any special advantage for the 50 volt lamp, which is claimed to be specially adapted for alternating work. It certainly increases the size of the inside wiring as compared to the 110 volt lamps, and places that part of the alternating installations in antagonism to the principle which is claimed to be so advantageous in the exterior conductors. No doubt lamps of the same voltage from different manufacturers will vary considerably in results.

A recently published article in regard to the incandescent lamps, written by John W. Howell, who is a high authority, says that lamp renewals should not exceed 15 per cent. of the operating expense of a central station plant. I am not aware that the cost of Edison 110 to 120 volt lamps exceeds this figure, nor that the Edison company is unwilling to guarantee an equal number of lamps to the horse-power and an equal life with any other lamp in the market.

An admirer of our friend, Mr. Cutter, says he always likes to hear him talk. I confess that during the progress of this discussion Mr. Cutter has helped me to understand how it is that the Thomson-Houston company secured such a large slice of the electric business, for his talk is very plausible. As against his theory that the eye judges the light at the instant of maximum incandescence when the impulses are in the lamp, and hence that the alternating current may be more economical than the constant current in the incandescent lamp, I want to suggest that the successive impacts of the alternating current must have a tendency to impair the structure of the carbon, for in my experience rapid changes in current have been a fruitful cause of brevity of lamp life.

I must also take exception to Mr. Cutter's view that a conduit system with small ducts through which conductors can be hauled from time to time between man-holes located at convenient distances is the most desirable. The experience with this system in Chicago certainly does not bear out this conclusion. If with a high tension alternating system it is going to be necessary to have new conductors hauled in every few days because those in use burn out, I can understand part of the necessity for such a construction. How such a conduit system is adapted to an electric distribution from which taps must be taken every few feet in order to enter buildings, is not clear to me.

Considering the expense, I still believe the Edison system of underground conductors, all things considered, the best which has yet been devised for incandescent work. It is easy to increase the thickness of the iron casing if the soil makes it advisable to do more than guard against mechanical injuries. I am aware that the Chicago troubles with the high tension underground conductors have been greatly lessened recently by a heavy increase of the insulation employed. This is a fact which stares the alternating current in the face. Large first cost for insulation and constant care and expense to maintain apparatus to prevent an undue percentage of waste in the current supply. The feeders in an Edison 3-wire system are usually figured at 10 per cent. loss, the distributing mains at two per cent., and the inside wiring, at the same, or a total of 14 per cent., under conditions of full load. As has been stated, the percentage of loss of current in the conductors is proportional to the load, so that the average loss is much smaller, say, five or six per cent. With the alternating current the opposite is exactly the case, for the converter has its

highest efficiency with the maximum load, but runs down materially as the load decreases. The alternating current system being practically confined to the sale of light for the present, and the maximum capacity of the converters being seldom called into use in a general lighting system, the advantage seems to be against it for economic use for distances which the constant current system attempts to supply.

I have always been strongly in favor of selling current for the incandescent light by meter measurement, and thereby profiting from the long experience of the venders of artificial gas. I am well aware that there are Edison central stations selling light by the contract system which earn 20 per cent. on their capitalization, but such cases are exceptional and it is my conviction in the long run that method will not be found satisfactory either to the customer or the companies. There are now thousands of Edison meters in successful use, and until the alternating companies shall perfect a meter and put it into extended use, the lack of this will continue to be a great objection to that system.

Allusion has been made several times to the excessive cost of the ground upon which the Edison stations are located, and I still want to say a few words on this branch of the subject. It has been stated to the club that in Boston capital has been offered to the Edison company to erect a building sufficiently large to accommodate the station and provide enough additional room for rent to pay a handsome profit on the investment in the ground and building. Our president has suggested that as other large corporations frequently provide their own accommodations in this way, electric light organizations may do so also.

The Chicago Edison company cannot be accused of any effort in this direction, but is evidently inclined to meet its fate strictly in the line of the sale of electric energy. I desire to repeat the statement heretofore made by myself that when a station is centrally located the sale of exhaust steam for heating purposes to surrounding buildings should become a large source of revenue. In combination with the Johnson heat regulating apparatus, especially favorable results can be obtained. The Chicago Edison station already has applications for steam heat, and I have no doubt this source of revenue is to become an important factor in electric lighting stations. When a station is located in the suburbs the exhaust is necessarily thrown away.

It should be distinctly understood that I am no alarmist in regard to danger from electric lighting currents. I believe there is no electric lighting in use which begins to compare in danger to property and life with gas. Still the fact that it is thought advisable by some to ground the secondary circuits and by others to ground a metallic shield between the primary and secondary coils in the converters for the protection of customers of the alternating system is in itself a confession of danger. Either method appears to me to make a series of first-class lightning arresters out of the converters, well calculated to protect the community at large at the expense of the pocket books of the stockholders in the alternating companies. In Edison's early work on the incandescent light he frequently expressed the determination to devise a system which by no possibility could injure any man, woman or child. That was a noble ambition, and I for one shall be sorry to see for economic reasons his system for general use so modified that this element of safety cannot be claimed for it.

A gentleman connected with a life insurance company recently stated to me that his company had decided to make all employés engaged in the the dynamo room and on line work of the alternating special risks, the same as the arc light employés. This is not the case with the employés of the low tension constant current system. The public has a right to demand the highest standard of safety in electric lighting, and there have been few more commendable things done in this city than the establishment of a rigid inspection of electric light plants, vexatious as Brother Haskins sometimes makes himself. The tendency of legislation and the courts is to hold corporations to a strict accountability for losses and injuries arising from carelessness of employés, in management and construction. It will be absolutely necessary in using high tension alternating or constant currents to maintain a high standard of insulation and efficiency to avoid the assessment of heavy damages in case of accidents. In this respect the low tension constant current system has a great advantage over high tension alternating currents; even where a high tension constant current is transmitted a long distance and converted by a motor generator, there is less risk, for in case of accident at the station it would be quickly discovered and remedied by the attendant, while with the alternating current it is possible to bring a death current within reach of the individual users of the light where the danger might not be discovered until a fatality had occurred.

Mr. President, I owe the gentlemen connected with the club an apology for not having brought with me a diagram to illustrate the subject under consideration. I contemplated bringing a picture of a 15-story office building with the windows omitted and a system of converters substituted in their stead. I thought it probable from the brilliant way in which converters appear to some of us that with such an arrangement by opening them on the inside, tenants would get all the light they wanted without the aid of the sun or additional apparatus. Such an illustration would be, in my opinion, about as fair as some of the diagrams shown here of the wires which cover northern Minnesota so as to shut out the buildings in St. Paul from view. If the club will excuse my neglect in not bringing the diagram on this occasion I will promise to make amends in the future. I make this pledge all the more freely because promises and futures seem to have a current value when electric distribution is under consideration.

THE EDISON LAMP PATENTS IN ENGLAND.

THE action of the Edison and Swan United Electric Light Co., Limited, *v.* Holland and others, was commenced at the Royal Courts of Justice, before Mr. Justice Kay, April 17th, to restrain infringement of Edison's patent for the filament, No. 4576 of 1879, and Cheesbrough's (Sawyer-Man) "flashing" patent, No. 4847 of 1878. The Attorney-General (Sir Richard Webster), Mr. Aston, Q. C,, Mr. Moulton, Q. C., and Mr. Bremner, instructed by Messrs. Ashurst, Morris, Crisp & Co., appeared for the plaintiffs; and Sir Horace Davey, Q. C., Mr. Finlay, Q. C., and Mr. Graham, instructed by Messrs. Renshaw, for the defendants. These two patents have already been the subject of litigation, in the case where Messrs. Woodhouse & Rawson were defendants, and plaintiffs were successful, both before Mr. Justice Butt, in the first instance, and subsequently in the Court of Appeal. The present case is of importance, because if the defendants succeed in establishing the invalidity of those patents, the manufacture of incandescent lamps will be thrown open to the public.

The case arose as follows: Holland, purchased the lamps complained of from the Jablochkoff company, for illuminating the Albert Palace; that company purchased them under indemnity from the Anglo-American Brush Electric Light Corporation, Limited, which obtained leave to defend the action, and are therefore the real defendants. The attorney-general opened the case by describing the inventions contained in Edison's and Cheesbrough's specifications, and pointed out that among the merits of Edison's invention one of the most conspicuous was the carbonizing of the filament after it had been formed. He dwelt upon the fact that no practical incandescent lamp had been made, or described, before Edison's patent, and that soon after that date such lamps were made and sold, and have since been made and sold in millions. So far as the plaintiffs were aware, the only lamp which came at all near to Edison's was made by Mr. Swan, early in 1879 or in the autumn of 1878, at Newcastle, where it had been publicly exhibited by him at lectures. This lamp, which was produced, contained a thin straight pencil of carbon of circular section about 1¼ in long and $\frac{1}{16}$ in. in diameter, enclosed in a glass egg-shaped vessel, from which the air had been exhausted. The carbon pencil was supported at each end by platinum wires fused into the glass.

Sir Frederick Bramwell was called on behalf of the plaintiffs. He was examined by Mr. Aston, and cross-examined by Mr. Finlay, who endeavored to elicit from him the fact that Edison had not given sufficient information to enable a skilled workman to carbonize a filament, especially by reason of his having omitted to state that in carbonizing it is absolutely necessary to exclude the air from the vessel in which the filament is carbonized. Sir Bramwell stated that in his opinion the vessel might be packed with sand, to exclude the air, and that this would succeed. Sir Bramwell was asked whether he had ever seen any lamps made according to Edison's specification without additions; and although he at first stated that he had seen one lamp so made out of a carbonized cotton thread, he subsequently admitted that the thread had been treated with sulphuric acid to parchmentize it before carbonization, and that he had never seen Edison's directions pure and simple followed. Sir Bramwell was then pressed to state the advantages to be obtained from the use of a filament, and was unable to point out any except that of high resistance. The witness admitted that electricians at the date of the patent were perfectly familiar with the laws of electricity, and knew both how to obtain high resistance, and what were the advantages resulting from it; and this was more especially the case with Mr. Lane-Fox, who had explained the whole theory of electric lighting in a marvellously clear manner in several specifications of his patents taken out before the date of Edison's patent. In fact, had Mr. Lane-Fox only made use of the term carbon in his specifications, he would apparently have given all the information to the world which the plaintiffs now wish to place to the credit of Mr. Edison. The witness was asked to explain how Mr. Swan's lamp differed from Edison's. At first witness endeavored to differentiate them by suggesting that the pencil of Swan's lamp had been cut out of a larger piece of carbon, that is to say, had not been in the form of a pencil before it was carbonized; but, when pressed, admitted that Swan's pencil might have been made either way. Upon various chemical points, arising on both Edison's and Cheesbrough's specifications, more especially upon a very remarkable passage in the latter—in which Cheesbrough says that his invention is not confined to the treatment of carbon alone, but

includes many infusible non-conducting bodies—Sir Bramwell gave no opinion, preferring to leave them to the chemical witnesses.

The next witness on behalf of the plaintiffs was Dr. John Hopkinson, who agreed generally with Sir F. Bramwell except upon the question of the use of sand for excluding the air in carbonization. He thought that a competent working man would know that he must avoid using sand, the use of which would certainly lead to failure in the case of fine filaments, inasmuch as they would, without doubt, be burnt in the carbonizing vessel by the air contained in the interstices of the sand. Dr. Hopkinson expressed a decided opinion upon the chemical questions arising on the specifications of both Edison and Cheesbrough; but, like the last witness, he admitted that he had neither made nor seen any experiments on the subject.

Mr. John Imray was then called. He had not made any lamps according to Edison's specifications, but had made experiments as to the electrical properties of certain lamps made by some person in the employment of the plaintiffs, and which, he was told, had been made according to Edison's specification. Nearly all these lamps had the globes discolored. Sir Horace Davey asked the witness to point out any material point in which one of the lamps produced made from cardboard and said to be constructed according to Edison's specification, differed from Swan's lamp. The witness was apparently unable to point out any material distinguishing feature.

Mr. Gimingham was next called, and stated that he had followed precisely almost all the different methods described by Edison for making a filament, and had succeeded in the whole of them. He further stated that he had tried the lamps so made for duration, and found the average life to be a considerable number of hours.

The last witness for the plaintiffs was Dr. Fleming, the electrician of the plaintiffs, who agreed in the main with the evidence given by the others. He, however, stated that secret processes were used in every stage of the manufacture of lamps by the plaintiffs, an admission which would seem scarcely consistent with the opening statement of the attorney-general, that millions of lamps were made by the plaintiffs according to Edison's specification.

Mr. Aston stated that that closed the plaintiffs' case.

Sir Horace Davey then opened defendants' case. He said that he intended to rely upon the following grounds, viz., that Edison's patent was bad for want of novelty; that his specification did not contain sufficient directions to enable a competent working man to make a filament of carbon; and that if the Court construed the specification in the way in which he construed it, there was no infringement, but if construed as the Court of Appeal had construed it he would admit infringement. Lane-Fox's patent, taken out in October, 1878, contained a statement of the principles which lie at the bottom of a successful incandescent lamp to be used in a system of parallel distribution. It was there stated that the lamp must have a high resistance, and that the electromotive force must be considerable, say about 100 volts. A subsequent specification of Lane-Fox's was also referred to, which came very near Edison's, except that Lane Fox, instead of saying "I make use of carbon," had stated that he used certain metals "or other suitable material." Sir Horace Davey then passed on to the consideration of Swan's anticipations, and said that he hoped to prove, that from as early as 1877, but certainly from 1878, Swan was engaged at Newcastle, with the assistance of Mr. Stearn, at Rockferry, near Birkenhead, in making incandescent lamps, and that he succeeded in making not only lamps with straight conductors, but with more or less filamentous conductors, in some cases from carbonized paper. Speaking of the "stick" lamp produced in court by the Edison company, the one frequently exhibited by Swan at lectures before the date of Edison's patent, Sir Horace said: "It cannot be denied, and I think it never has been denied, that this lamp is identical with Edison's specification, unless you can distinguish it on the ground that this carbon conductor does not come within the description of what Edison meant by a filament." It had been said by the plaintiffs that it was a lamp of low resistance, three to five ohms, and no doubt it was so, although its exact resistance could not now be ascertained, for after a "litigious" life of 10 years, the carbon had become damaged. The lamp was composed of a straight stick of carbon about 1¼ in. long and $\frac{1}{16}$ in. diameter, mounted between two platinum wires in a glass globe, from which the air had been exhausted. The globe was considerably dimmed by deposited carbon. The occluded gases had not been removed by Mr. Swan when he constructed the lamp in 1879. Sir Horace Davey then proceeded to point out the main lines of attack which he proposed to make on Edison's specification. He said that Mr. Edison had added nothing to the stock of knowledge possessed by the public in 1879; that he had not given sufficiently clear and definite instructions to enable a skilled workingman to make a lamp without considerable experiment; that he had in fact done nothing more than make a series of suggestions which he had not worked out in his own mind, but had left to be worked out by subsequent experimenters; that the mere statement that a combination of a carbon filament within a receiver entirely of glass through which the leading wires pass, and from which receiver the air is exhausted (Edison's second claim), was nothing more than a statement of a desirable object which electricians had in view. Sir Horace then went on to discuss the meaning of the word "filament," and pointed out that the witnesses who had been called for the plaintiffs had been unable to give anything like an accurate definition of a filament, and would not commit themselves by stating where a filament ended and a pencil began. He should argue that Edison had deliberately abstained from making his meaning clear, and that a patentee was rigorously bound in law to put up such a fence that everyone coming within that fence would be coming upon forbidden ground, and Edison had erected no such fence. Sir Horace then dwelt on the fact that, with the exception of a few lamps made for use in the former action against Messrs. Woodhouse & Rawson, and in this action, plaintiffs had not been able to produce a single lamp made according to the directions in Edison's specification without the addition of other processes or improvements, although the counsel for the plaintiffs and their scientific witnesses had spoken of the world-wide Edison lamp which had created a revolution in electric lighting. Edison himself had taken out several subsequent patents, in two, at least, of which he had given further instructions in the processes of manufacture. In one of these he had stated that purely structural carbon was the only carbon which would answer; the greatest possible condemnation of that portion of the specification in question which claimed filaments made by carbonizing lamp black and tar. He then proceeded to cite certain decided cases, which, he contended, showed that Edison's specification was invalid.

Sir Horace Davey then went to the other patent, viz., Cheesbrough's, which is a patent for an invention made by Messrs. Sawyer and Man, in America. The invention consists in placing the filament in a vapor of hydro-carbon, and then passing the electric current through it, so as to raise the conductor to a yellow heat. At that temperature the hydrocarbon is decomposed, and carbon is thrown down in a very beautiful manner upon the filament, the deposition taking place most rapidly at those points on the filament where the temperature is highest, which are the places where the filament is thinnest. By this means a filament of uniform electrical section is rapidly obtained. Sir Horace Davey stated that the anticipation upon which he intended to rely chiefly was a paper published by the eminent French chemist, M. Despretz, many years ago. M. Despretz had been anxious to ascertain whether he could fuse or volatilize carbon. He had placed carbon in the electric arc, and he had also passed a current of electricity through the carbon, and in the course of his experiments he had surrounded the carbon with nitrogen; but he found that some chemical action took place between the carbon and the nitrogen, and he then hit upon the idea of placing the carbon in a hydrocarbon atmosphere. To his astonishment the hydrocarbon was decomposed, and carbon was deposited not only on the piece of carbon operated upon, but also on the clamps in which it was held, and on the glass vessel containing them. Sir Horace also stated that he intended to rely upon that passage in Cheesbrough's specification in which he stated that his invention was not confined to carbon alone, but included many other infusible non-conductors, as for example lime.

Robert Percy Sellon, the chief electrician of the Anglo-American Brush Co., was called for defendants. He described the process by which the Brush company had made the lamps complained of. That process, which is to some extent covered by patents, consists in taking cellulose in a pure condition and dissolving it in chloride of zinc, producing a jelly-like substance, which is forced through a small circular aperture into alcohol. The effect of the alcohol is to cause the cellulose to deposit in long fine homogeneous threads, which are very carefully dried on velvet, and then wound upon moulds the shape of the filament when finished, and the whole placed in carbonizing crucibles, packed with charcoal, and raised to a high temperature, care being taken to exclude the atmosphere, and to allow for the contraction of the filaments during the process of carbonization. The filaments are then mounted in clips and flashed for a few seconds only, so as to bring them all to the required resistance. The filaments are next mounted on the platinum wires, by again flashing the surfaces where the carbon and platinum touch, and are then ready for mounting in the lamp and for having the globes exhausted and the occluded gases taken out. Mr. Sellon was examined at some length as to the insufficiency of the directions in Edison's specification, and especially as to carbonizing, and the injurious effect alleged to be produced on the platinum leads by putting them into the carbonizing chamber in those cases where the filaments are mounted to the platinum before carbonizing. Mr. Sellon was then cross-examined by Mr. Aston, and admitted that in one or two of the papers in evidence in the case there were directions given for putting powdered charcoal into the crucible when carbonizing carbons to be used for arc lighting, especially in a description of the process adopted by M. Carré.

The next witness was Professor Crookes, who was examined by Mr. Graham. He described very minutely a large number of experiments which he had made upon the directions contained in

Edison's specification, and which he had found the greatest difficulty in following, having failed to produce a lamp of any commercial value by any of them. Professor Crookes also described some very remarkable experiments which he had made upon that portion of Edison's specification where it is stated that the filament may be coated with some non-conducting non-carbonizing body. He coated the filament with asbestos, fire clay, and other similar substances, and found that at temperatures below those which are usual in a lamp, a chemical reaction takes place between the carbon and the oxygen in those substances, the carbon burning off as carbonic acid. Professor Crookes had also made similar experiments with respect to the passage above referred to in Cheesbrough's specification. He took a small pencil of carbon, and surrounded it with lime, and passed the current through the carbon, while it, with its lime envelope, was surrounded by a hydro-carbon gas. Carbon was deposited throughout the pores of the lime. The witness then cut a small pencil out of the lime, impregnated with carbon, and mounted it in a lamp, which was then exhausted. When the vacuum was as good as that usually obtained in lamps, Professor Crookes passed the current through, and before the usual lamp temperature was reached a reaction commenced. The filament began to scintillate, and broke down immediately. Experiments of a similar character were made with magnesia and other bodies with similar results. Professor Crookes was cross-examined at great length by the attorney-general, and admitted that many of the references in Despretz's experiments were made with the arc phenomena and not with incandescent carbon.

In reply to further cross-examination, the witness referred to several passages in Edison's subsequent patents, in which was pointed out the necessity of careful carbonization to prevent warping, twisting, etc., and to allow for contraction, which he stated to be inevitable; and speaking of Edison's suggestion to coat the filament with a non-conducting non-carbonizing substance, he pointed out that the action of these substances upon the filament when placed in the lamp would depend to a very great extent upon the condition of the filament itself. If the filament were a hard homogeneous carbon, and the silicate easily fusible, the silica might run off without attacking the carbon, whereas, if it were a soft porous carbon, it would absorb a fusible silicate like a sponge, and be destroyed when the temperature rose high enough. A lamp handed to Professor Crookes by the attorney-general, which had been coated with a non-conducting non-carbonizing substance was, in Professor Crookes's opinion, made with a filament of thread treated with an acid prior to carbonization. He did not consider this a fair example of the Edison filament described in the specification. He also stated that he had himself experimented with a very large number of substances as coatings for filaments, and without a single exception had found them all the reverse of beneficial, by reason of their diminishing the radiating power of the carbon. Returning to the subject of carbonization, it had been suggested to the witness, in cross-examination by the attorney-general, that gases were given off during carbonization, and expelled the air from the crucible. On this point Professor Crookes stated that at the comparatively high temperature at which these gases would be formed, the mobility of the molecules would be much increased, and they would diffuse out rapidly at the same time that the atmospheric air would diffuse in: the luting of the crucible would by this time have become quite dry, and permeable to gases.

The next witness called by the defendants was Dr. Frankland. He stated that he lighted his house five or six years ago with incandescent lamps obtained from the Swan company before their amalgamation with the Edison company. He remembered the exhibition of lamps at Mr. Spottiswoode's house in December, 1880, on which occasion Mr. Swan explained their construction. The first time he saw an Edison lamp was at the Crystal Palace Exhibition in 1882, when Mr. Sprague, Mr. Edison's agent, presented the witness with an Edison lamp, which he produced. This, in Dr. Frankland's opinion, was made of a bamboo filament, and not according to the directions contained in the specification now in question. The carbon filament appeared to have been mounted to the platinum leads by some electrolytic process, and the witness had never seen, in the market, an Edison lamp in which the filament was mounted in the manner described in the specification. Dr. Frankland stated that he had endeavored to make a putty-tar filament, but had not been able to roll it out finer than one millimeter in diameter. He did not attempt to carbonize any of these filaments himself; but he saw an experiment made by Professor Crookes, in which the crucible had not been packed, and all the filaments, including some made of structureless cellulose, were entirely burnt up, leaving nothing but ash. He corroborated Professor Crookes as to the effect of coating the filament with the non-conducting non-carbonizable bodies, and also as to the effect which the carbons would produce on the platinum if the platinum were attached to the filament before carbonizing. In his opinion, at the date of Edison's specification, the word filament had acquired no technical or conventional meaning, except in botany, and there it meant, in some cases, a thing of considerable diameter as compared with its length. Speaking of the experiment which Professor Crookes made, where a fine pencil was cut from a stick of lime, which had been impregnated with carbon by flashing in a hydrocarbon gas, and the pencil then placed in a lamp, Dr. Frankland stated that he was looking through a spectroscope at the time, and after a minute or two he saw the calcium hues in the spectrum; soon afterwards the lamp broke. He had carried out Despretz's process, and produced a material identical with Cheesbrough's. If the platinum had been placed in the carbonizing chamber, and had thus to some extent been converted into a carbide, then at the time of sealing the platinum into the glass a considerable length of the platinum would be heated to a red heat, and the carbon in the carbide of platinum would burn off, leaving the wires in a very porous state. Dr. Frankland was then cross-examined at length by the attorney-general. The witness was the principal scientific witness in the action brought by the present plaintiffs against Woodhouse & Rawson. He admitted that the only experiments which he had seen since that trial were those performed by Professor Crookes, and further that during that trial he had not said anything about the insufficiency of Edison's specification, or on the point which had been raised recently about the formation of carbide of platinum. The witness had stated at the last trial that in an old specification filed by Pulvermacher there were sufficient directions to enable a skilled workingman to make a carbon filament such as Pulvermacher describes; and he admitted that he was still of the same opinion, but that more specific instructions would be required to enable a workingman to carry out the process, because carbonization, so far as it was known at the date of Edison's patent, always meant partial combustion of the thing being carbonized. Dr. Frankland was then asked by Sir Richard Webster whether he was not aware that in February, 1880, there was an exhibition of Edison lamps in Queen Victoria street, on which occasion Dr. Fleming explained their construction. Dr. Frankland stated that he was not. The witness was then asked about the experiments with the lime pencil impregnated with carbon, and admitted that he had not made the experiments for himself, but was present when Professor Crookes carried them out. He said that the bright calcium hues were due to the metal calcium being in a state of vapor, and that calcium would only pass into that state at such high temperatures as that of the electric arc. On re-examination, Dr. Frankland stated that the list of infusible non-conducting substances previously referred to as having been put in by Professor Crookes, specifying some 40 or 50 bodies, did not by any means exhaust the number of bodies answering to that description, but was a list of those most likely to succeed, although in his opinion not one of them would succeed. He added that this point on Cheesbrough's specification, and the analogous one as to non-conducting non-carbonizable bodies mentioned in Edison's specification, was not referred to at the last trial, on which occasion the sufficiency of Edison's and Cheesbrough's specifications was hardly mentioned.

Dr. Tidy, who had given evidence on behalf of the plaintiffs as to Cheesbrough's patent at the last trial, was examined on behalf of the defendants. He stated that he had put 50 filaments into a crucible, and carefully luted the top and raised it to a carbonizing temperature, and had found nothing but ash on opening the crucible. He then filled the crucible with charcoal, and succeeded. He then tried making putty-tar filaments, and pointed out that Edison gave no directions as to the proportions of tar and lamp black. If you put too much tar, the mixture ran; if you put too little, the substance came to pieces. After a great many trials he got a filament about $\frac{1}{16}$ inch diameter, which he carbonized with charcoal; but he found, on opening the crucible, that it fell to pieces. He considered it was necessary to use a mould in carbonizing, which would allow for contraction and prevent distortion. Dr. Tidy was then cross-examined by Mr. Aston, and admitted that it was possible to carbonize a cotton thread, but denied that a putty-tar filament could be subjected to a carbonizing process, and come out as a filament, which could be used. Dr. Tidy had also coated a thread with tar and lamp black, and he had found that the coating cracked in carbonizing. He admitted that in one of the specifications prior to Edison there was a description of carbonizing carbons to be used for arc lighting in contact with powdered charcoal. Dr. Tidy stated that in carbonizing there were two factors which had to be taken into account: the temperature at which the carbonizing was effected, and the rate at which the temperature was raised.

Professor Silvanus Thompson was the next witness. He was examined by Mr. Finlay as the principal witness to speak to the electrical aspect of the case. Professor Thompson stated that he visited the house of Mr. Stearn, at Rockferry in the autumn of 1880, and observed that it was lit with electric lamps, the conductors of which were of a filamentous character. He saw many Swan lamps at the meeting of the British Association at York, in August, 1881, and the first time he saw an Edison lamp was at the Paris Exhibition, in September, 1881. Those lamps, he said, would come within the second claim of Edison's specification, but had been made with many improvements not mentioned in that specification. He pointed out nine respects in which they

differed from those described in the specification. Professor Thompson then produced diagrams showing the different ways in which lamps could be used, that is to say, in series, in multiple arc, and in a combination of the two. And he explained that the advantage of high resistance in lamps was an advantage external to the lamps; a lamp of low resistance being more durable than one of high resistance. With high resistance lamps small mains could be used, whereas with low resistance lamps the mains would be large. The witness referred to passages in Lane-Fox's and Edison's patents prior to the one in question where this had been pointed out, and to a specification of Edison, in which he had himself pointed out the advantages of low resistance lamps in certain cases. He produced specimens of Carré carbons which he bought from Mr. Carré in 1878, which were one millimeter in diameter, and had originally been one meter in length, and said that at that time they were the most suitable forms of carbon for use in incandescent lamps. Professor Thompson further stated that the real difficulty of fusing platinum into glass depended upon the glass and not on the platinum. Glass differs much in its rate of expansion, and if a glass is taken which has the same rate of expansion as the platinum, there is no difficulty in sealing platinum wires into it. Professor Thompson was cross-examined by Mr. Moulton, and was much pressed for the purpose of elucidating from him that the pencil of lime impregnated with carbon and put into a lamp by Professor Crookes, was not of uniform section, and that the consequence of this would be that at those portions of the pencil where it was thinnest, the heat might have risen to that due to the arc, while the other portions were still at a low yellow heat, and thus a chemical reaction between the lime and the carbon might be induced at one particular spot, while the rest of the pencil appeared to be at a low temperature.

The next witness was Professor Perry, who stated that one of the great factors which made incandescent lighting possible was the improvement in the dynamo machine. The first Gramme dynamo brought into England was shown by the witness to a number of scientific gentlemen in 1874, to whom the machine was quite unknown. In 1878, Brush took out his patent for compound winding, but the merits of compound wound machines were not generally recognized until a year or two after that date. Professor Perry stated that in his opinion it would not have been safe, having regard to the nature of the dynamos then in the market, to use a lamp with a carbon conductor much smaller than that used by Mr. Swan. The advantage of the compound winding was pointed out to be that you may switch on a hundred lamps or more, and switch them all off but one, without producing any material difference in the electromotive force. Professor Perry was cross-examined by the attorney-general, and said that he thought the gold medal which was awarded to Mr. Edison at the Paris Exhibition was not for his lamps alone, but for his telephone, phonograph, and other things also.

Mr. James Swinburne was then examined by Sir Horace Davey. He stated that about 1881 he was with the Swan company at Newcastle, and that great difficulty was experienced in properly carbonizing the filaments. After some weeks of experimenting, the method had been devised of winding the threads on such a frame as that spoken of by Mr. Edward Gimingham. At one time the Swan company carbonized each filament separately in moulds. Mr. Swan, towards the end of 1880, had taken out a patent for carbonizing filaments in powdered charcoal. Mr. Swinburne had tried long ago to carbonize in sand, and had failed, and quite recently he had measured the quantity of steam and air which came off sand, and he found that 140 cub. cm. of silver sand gave off as much steam and air as would burn up 25 to 50 filaments. A sample of grey sand tried by Mr. Swinburne of the same volume, gave off 27,000 c. m. of steam and air. Mr. Swinburne stated that he had considerable experience in testing incandescent lamps, and that he did not think the duration tests which had been made by Mr. Gimingham had been sufficiently hard ones. Mr. Gimingham had tested the lamps at about 16 watts per candle-power, whereas Mr. Swinburne considered $3\frac{1}{2}$ to 4 watts a more satisfactory test. It was the one which he usually applied.

Before proceeding to cross-examine Mr. Swinburne the attorney-general stated that he was willing to admit that the carbon conductor in Swan's stick lamp had been made by Carré, in Paris, and had received its present form before carbonization. It will be remembered that in the former trial against Woodhouse & Rawson, Sir Frederick Bramwell stated that, to the best of his belief, this carbon had been worked down from a thicker piece, and not carbonized in its present form, and in this opinion he was corroborated by the other witnesses for the plaintiffs. Mr. Swinburne was then cross-examined with a view to show that if the material used in carbonizing contained such a large quantity of sand as he had spoken of, the steam would have driven all the air out of the crucible before the temperature had been reached at which the air would begin to combine with the carbon.

Mr. Alexander Bernstein was then examined by Sir Horace Davey. He stated that he had sold large numbers of lamps in which the carbon was $\frac{1}{16}$th of an inch in diameter and from $\frac{3}{4}$in. to $2\frac{1}{4}$in. long, and that they were used in series with perfect success, especially in the United States. When he went to America in December, 1880, he could find no Edison lamps on the market; but on visiting Mr. Edison at Menlo Park he found him making lamps with filaments of bamboo. On being cross-examined by Mr. Aston the witness mentioned one or two places where his lamps could be seen in use in this country, but declined to name any others. Mr. Justice Kay intimated that the witness's objection was natural, as he was possibly afraid that Mr. Aston was laying the foundation for a case against him. This was the last witness called by the defendants on the scientific aspect of the case, the next witnesses giving evidence as to what they had seen in Newcastle at Mr. Swan's place of business during the years 1878 and 1879.

Mr. Proctor, a scientific gentleman, residing in Newcastle, remembered Mr. Swan exhibiting a broken lamp to the Chemical Society of Newcastle on the 19th of December, 1878. This lamp was a good deal blackened on the inner surface; it had contained a small straight pencil of carbon, which had been ruptured. Mr. Proctor had analyzed the black coating on the glass, and subsequently read a paper on his investigations. Mr. Proctor was also present at Mr. Swan's celebrated lecture on the 3rd of February, 1879, on which occasion the stick lamp was exhibited and incandesced for some time. It was worked from a dynamo and burnt steadily, giving a comparatively good light. Several hundred persons were present, and Mr. Swan explained the construction of the lamp. The witness then stated that during the summer of 1879 he had seen many lamps of various constructions at Mr. Swan's works in Moseley street, some being made of paper and some of thread; and that he had seen some of these of an arched or horseshoe form, which must have been carbonized after they had received that form. These lamps were incandesced in Mr. Swan's works, and gave out 10 to 14 c. p. Mr. Proctor was cross-examined at some length by the attorney-general for the purpose of showing that his memory was in fault, and that he saw these lamps in 1880 and not in 1879.

Mr. Arthur Heaviside, superintending engineer of the postal telegraphs at Newcastle, had known Mr. Swan very intimately during the years 1878 and 1879, and had tested a number of lamps for Mr. Swan in the summer and autumn of 1879 for the purpose of ascertaining their resistance. The lamps contained thread-like burners in some instances, and in others flat strips of carbonized material bent into an arched form. The witness was able to fix the date of his tests by his notes of lectures delivered to a scientific class about that time. Mr. Heaviside was cross-examined at considerable length as to the accuracy of his dates, and stated that he had not only seen threads in a horseshoe form, but also with a double twist at the end of the horseshoe.

Mr. Patterson, who carries on business at Gateshead as an earthenware manufacturer, was then called, and stated that he had on several occasions before November, 1879, taken strips of paper, packed in powdered carbon, to be carbonized in his father's pottery furnaces; and he remembered Mr. Swan exhibiting his lamps in the workshop, and at the lectures, where he on one occasion assisted in fitting up the batteries. He left Mr. Swan's employment in January, 1880.

The next witness was Mr. Mayfield, of Queen Victoria street, London, who had been the manager of Mr. Swan's scientific department until October, 1879. He corroborated the three preceding witnesses as to the experiments made by Mr. Swan in the autumn of 1879 with slender carbon burners. Several witnesses of minor importance were also called to speak to the same point, and this brought the defendants' case to its close.

Professor Dewar was then examined by Mr. Moulton, for the purpose of giving rebutting evidence on behalf of the plaintiffs. He stated that directions to enclose the filaments in powdered charcoal when carbonizing were wholly unnecessary, inasmuch as persons with an ordinary amount of skill would know that this was desirable. He produced carbon filaments which he had made by carbonizing in sand inside one crucible which he had placed in the carbonizing chamber in the inside of another crucible, and stated that none of the filaments had been attacked by oxygen, and that he had actually made a lamp from a filament of broom carbonized in that way. Professor Dewar stated that there was no difficulty in rolling out a filament of lampblack tar, and he proceeded to roll one in court to a very considerable fineness. He had mounted a filament so prepared in a lamp, and run it for a couple of hours. He had also rolled out filaments of lampblack, containing camphor and oxide of zinc, and carbonized them; but had not mounted them. The witness also produced lamps in which the filament had been coated with silicate of soda and alumina. He had conducted several experiments with Despretz's process, the result being to completely disintegrate the carbon, owing to the very powerful currents used by Despretz; and he distinguished Despretz from Cheesbrough, because the latter pointed out that it was necessary to gradually increase the current during the flashing, which point Despretz did not mention. The witness stated that Cheesbrough's directions as to his alternative process, viz., impregnating lime with carbon, were not misleading, inasmuch as, if the carbon pencil surrounded with lime were put into the lamp, the lime cylinder would not crack off,

and would do no harm. This witness was cross-examined at great length by Sir Horace Davey, and admitted that in his experiments on Despretz he had used secondary batteries, and obtained from them more powerful currents than Despretz used, and that the gradual increase of current was not essential in Cheesbrough, but only highly advantageous.

Dr. Hopkinson and Dr. Fleming were recalled to add to the evidence already given by them, the latter admitting that the plaintiffs had never made any lampblack and tar filaments except for the purposes of litigation.

The next witness was Mr. Joseph William Swan, who deposed that he had never made any thread lamps before November, 1879. He gave an extremely interesting account of his early experiments and failures. Among other things he stated that from 1877 to 1880 he worked in conjunction with Mr. Stearn, of Rockferry, who mounted the carbons in his experimental lamps, and exhausted the glass bulbs. The lamp exhibited at the lecture in Newcastle, in February, 1879, was received the night before. He admitted that he thought the carbon in this lamp received its form before carbonization. Upon cross-examination by Sir Horace Davey, he said his chief means of fixing any dates as far back as 1879 were letters which he had received from Mr. Stearn. He was then asked to explain how it was that he had been present during the trial against Messrs. Woodhouse & Rawson, in which the witnesses for the plaintiffs had repeatedly stated that, in their opinion, this stick lamp had been made by rubbing it down from a larger piece of carbon, and that he had never corrected them or mentioned the matter to the solicitors. Mr. Swan explained that he was not there as a party to the action, but merely as a person who had been subpœnaed by the defendants, and he did not then know that it was a matter of extreme importance in the action. Reports of many lectures delivered by Mr. Swan in the years 1880-1-2 were then read, in which Mr. Swan was reported to have stated that after a perfect vacuum, such as Mr. Crookes had produced, was created in the lamp, there was nothing more to be done except to perfect the details of the lamp. The attention of Mr. Swan was called to the following extract from a paper read by him before the British Association, in York, in 1881, in which he said:

> Mr. Stearn undertook to mount some of my paper carbons in a good vacuum, and after many failures from carbons breaking, we at last succeeded in making some bulbs very highly exhausted, containing my paper carbons attached by electrically-dejointed copper to platinized strips, which carried the current in and out of the lamp.

The witness was asked when this was done, and replied that it was in February, 1879. An affidavit was then read which had been sworn by Mr. Swan soon after the Edison company attacked the Swan company about the year 1882, and shortly before the two companies amalgamated and became the present plaintiff company. The words of one paragraph of that affidavit were as follows: "I believe that the said letters patent of the said Thomas Alva Edison are void, not only by reason of the prior publication of the invention claimed, but also on account of insufficient description." And finally, two specifications of patents taken out by Mr. Swan in 1880 were put to him. In the first, he described the preparation of cotton thread by treating it with acid and carbonizing it; in the second. dated five days later, he described and claimed precisely the same invention with this difference, that he used powdered charcoal in carbonizing the filaments.

Reports thus far end here. Further reports of the proceedings will be summarized in these columns hereafter.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Competition among the Electric Light Companies.—The Question of Wire Distribution from the Subways.—Inspection of the Overhead Wires in the City.—The "Electric Death Chair."—Proposed Removal of "Dead" Wires.—Proposed Electric Railway in Brooklyn.—Opening of the Long-distance Public Reception Room.—A Cable Railway System to be Started in Newark, N. J.

THE competition between the various electric light companies which have recently made bids for street lighting in this city does not look very promising for those who hope to derive an income from dividends upon their stock The highest price now paid for this class of lighting is 35 cents per night, while in some districts the price is as low as 27½ cents, at which figure the Ball company was awarded 48 lamps. There also appears to be a very strong probability that these companies will soon be at considerable expense in the reconstruction of their lines to conform to the requirements of the board of electrical control. Measures have recently been taken which seem to require the various electrical companies to recognize the authority of the board, and with the appointment of an electrical expert it is very likely they will find some difficulty in framing suitable arguments to excuse them from complying with the rules of the board. The mayor, while withdrawing from active participation in its deliberations, finds time to occasionally give his views to the reporters of the daily press, and his latest stand is that the subways already provided are not suitable for the reception of electrical conductors. As no provision has as yet been made for local distribution, or the supply of facilities for connections along the various routes between man-holes, his position in that respect is no doubt well founded. An active campaign, however, has already been started against the "dead" wires, of which there are between 10,000 and 15,000 miles in the city according to various estimates. The inspectors appointed by the board are bringing in daily reports from their various districts, and the labor of complying with their requests for removal will make very active work among the linemen this summer. Even although it may not be the business of the companies to take down a large proportion of these "wild cat" wires which have been abandoned by their legitimate owners, the companies will, of course, find it to their interest to do so rather than leave the work in the hands of such vandals as the board of public works might choose to assign to that duty. It appears very probable that a similar policy may be adopted in other cities, and companies who may stand in fear of future underground legislation might do well to take the initiative in the movement. If more pains had originally been taken by the companies doing business in this city to build and maintain first-class lines their present troubles would probably never have come upon them.

Those who feel an interest in the subject of capital punishment by electricity may have their curiosity satisfied by visiting one of the Bowery dime museums which advertises among its other attractions "The Electric Death Chair." It is very probable that the design for this novel piece of furniture was taken from an illustrated article which recently appeared in a so-called journal of civilization.

The Brooklyn Heights Railroad Co., of which S. B. Chittenden, Jr. is president, has applied to the common council of Brooklyn for permission to operate an electric road through Montague street from Court street to Wall street ferry. There is also a petition before the council from the Wall Street Ferry Railroad for a cable railway franchise over the same route. Many of the abutting property owners object to this but they are interested in the other project. In the petition for the electric road it is claimed that $2,265,000 worth of property out of the $3,429,000 along Montague street is in favor of that system. Both petitions will be considered by the railroad committee.

The opening of the public room at the Telephone building, No. 18 Cortlandt street, for the accommodation of those who desire to use the long-distance telephone system, marks an important step in the development of electrical communication. Some little time will be required to educate the people as to its advantages, few being aware of the perfect ease with which a conversation may be carried on with a distant correspondent. The room devoted to this use is 30 x 20 feet in size, on the ground floor, and beautifully lighted. The floor is laid with tiles and the wainscoating is of Italian onyx. The walls are of a buff tint, and the general result is very tasteful, as might be expected from the usual work of this character undertaken by the New York telephone management. The telephone desks are arranged in separate cabinets within which a person may sit comfortably, and privately communicate with various cities in Massachusetts, Connecticut, Rhode Island, or with the most important points in this state, or south to Philadelphia. Messengers are kept at the office to notify persons whose presence at the office has been requested by correspondents in distant places. The company has also placed 100 long-distance transmitters in the "pay" stations in different parts of the city.

A very extensive system of cable railroads is proposed for the city of Newark, N. J., and a company has been formed for their introduction. The recent completion of elevated railways in Brooklyn, and the serious overcrowding of the New York lines makes it important that the cities and towns of neighboring districts in New Jersey should keep up with the times; but it seems strange that in a city so favorably situated as Newark electricity should be entirely ignored. Newark has been within the circle of electric activity since the conception of the Morse tetegraph, and it would appear fitting that if it is to indulge in rapid transit, electricity should be brought into use, especially as its adaptability for such work is no longer experimental, but has proved its merit under the most disadvantageous circumstances.

NEW YORK, June 25, 1888.

. . . . A man who is willing to adopt any good idea, whether it is his own or belongs to some one else, is apt to do better work than with a few ideas of his own, and no room for those of others. —*The Millstone.*

. . . . It is well enough, perhaps, to designate volts obtained by chemical action as equi-volts, but I do not know any reason for it. Really these equi-volts are just plain, ordinary, North American volts.—*Francis B. Crocker.*

PHILADELPHIA.

The Edison Company Busy in the Streets.—Other Electrical Affairs Dull.—The City Enjoined from Laying Conduits on Broad St.—Chief Walker's Views.

WITH the exception of the Edison Electric Light people, who are busily engaged in tearing up the streets in all directions in order to lay their wires on both sides of the Schuylkill river, electrical matters in this vicinity are rather dull.

Chief Walker, of the electrical bureau, was an angry man this morning.

The action of Judge Thayer in granting an injunction restraining the city from laying an electric conduit on Broad street, south of Federal, had completely upset him.

The action of the court he considered unjust, "and I am satisfied it would never have been taken," he added, "had the Judge known the facts. Briefly speaking, the history of the matter is simply this: Arthur McGinn had a contract to repave a portion of South Broad street with Belgian blocks. Before the blocks were laid the electrical bureau—in accordance with an ordinance of councils—opened proposals for the laying of a conduit under Broad street from the City Hall to McKean street, for the accommodation of the police and fire alarm telegraph wires and the city's electric light wires, the idea being to abandon and remove the poles on South Broad street just as soon as the conduit was finished. The supplies for the work were late in reaching us. Nevertheless a sufficient stock came to allow a force of men to begin work on the conduit a week ago. Inasmuch as contractor McGinn had begun at the northern end of his contract and was working southward, and inasmuch as my first object was to lay the conduit without tearing up any of his work, I started my men at Passayunk avenue with instructions to work northward until they reached the new paving. This they did. They took up nothing but old cobblestones, and at the time that the Court, upon McGinn's application, granted the injunction and stopped us, we were not within a square of his paving. The man is either crazy or devilish, for he had no reason whatever to take the course he did. We had no idea of tearing up his work. On the contrary, our main purpose was to avoid that very thing. Had the Court known the facts of the case, I am satisfied it would not have granted the injunction."

McGinn in his application set forth that if the laying of the conduit was allowed to proceed it would spoil his paving and prejudice his claim against the city. Chief Walker states that had he been allowed to proceed he could have laid the conduit without tearing up any of the new paving. As matters are now, about five hundred feet will have to come up.

PHILADELPHIA, June 18, 1888.

BOSTON.

The General Underground Conduit Bill Fails in the Legislature.—Cobb, Pulsifer & Co. Propose to go Ahead Nevertheless, Backed by the Boston Aldermen.—Novel Service of a Telegraph Pole.—Underground Agitation in Rhode Island.—The Snow-Alley Case.—Electric Lights at Malden.—The Fire at the Boston Edison Station; Energetic Action of the Edison Company in Restoring Service.

THE conduit business for Boston, and probably for the other cities in the state, has been clubbed severely, and apparently does not yet know that it is dead. In the legislature the general underground conduit bill was considered at great length on the 22d, 25th and 28th May, failing at passage at last in the senate.

In the senate Mr. Clark pointed out that the promoters of the bill were three men who had been granted exclusive privileges by the Boston board of aldermen, and they appeared before the committee to have this grant legalized. The board of aldermen attempted to exercise a right which they had no right to grant, and the purpose of the petitioners was not to preserve the safety of the citizens of Boston, but to enrich the parties who had exclusive privileges accorded them.

Mr. Clark said further that upon their visit to New York, Brooklyn and Philadelphia the committee were forced to the conclusion that in no city of the United States was there a system which admitted all kinds of wires in the same conduit, and that it was impossible to perfect such a system. The bill before the senate provides that the mayor and aldermen may establish and regulate the laying of these lines, whereas the statutes place such power in the city council, and it is to meet the peculiar state of affairs in the city that this change is made, a majority of the aldermen being favorable to this project, while the common council is opposed to it. This provision was actually put in to give the majority of the aldermen the power which the law as it stands denies them.

The rejection of the bill by the senate ended the conduit matter, so far as the legislature is concerned, for it adjourned without further action upon it; but the "American Conduit Company," have fallen back upon their friends, the eight aldermen of the city of Boston, and Henry E. Cobb, Royal M. Pulsifer and Francis R. Chapman have accepted the franchise granted them, by the board of aldermen for the exclusive right of the streets for twenty years in which to place conduits for carrying telegraph and telephone wires, and have filed a bond in $200,000.

On the 6th inst., at a meeting of the aldermen, an order, authorizing and directing the superintendent of streets to issue a permit to Henry E. Cobb *et al.* to open a certain street was laid over until the next meeting.

The following order was passed:

Ordered, that no more permits be issued for opening streets to construct conduits or lay electric wires without the approval of the board of aldermen. All orders inconsistent with this are hereby revoked.

This order was to shut off the various electric companies who have been and are now putting down conduits in locations previously granted by the aldermen from proceeding any further; meanwhile, the mayor has given orders to the superintendent of streets to allow no digging up of streets, and the police have orders to arrest any person so doing. Our mayor is a large owner of stock in the Brush Electric Light Company doing business in Boston, and has a personal interest against putting electric light wires into a conduit owned by another corporation.

At the board meeting on the 11th inst. the mayor vetoed the above order, in the following communication:—On grounds of illegality,—referring to the opinion of the corporation counsel on which his veto of the ordinance of May 7th was based.

A contemporary says: "The electric wires must never go underground. A telephone pole outside the Riverside base ball grounds converted what would otherwise have been a home run for Manchester into a three-base hit, one day last week." This would appear to be substantial reasoning

Down in Rhode Island the underground wire interest is rising. On the 22d ult., in the Providence common council session the resolution authorizing an application to the general assembly for authority to hire $30,000 to put the city's electric wires underground was indefinitely postponed.

Judge Pitman, in the Superior Court at Dedham, on the 22d ult., decided to grant the motion of Colonel Ingersoll for a new trial in the famous Snow-Alley case, on the ground that the verdict was not in accordance with the law or the weight of the evidence. Colonel Ingersoll is counsel for Mr. Alley. This case has been referred to before in my correspondence, and for several trials has gone in favor of Snow, but Alley is several times a millionaire, and seems to have a way of changing the venue into every circuit.

Malden was lighted wholly by electricity Friday night the 22d ult. for the first time. Nearly all the wires are in position. There are 76 arc and 205 incandescent lights.

At about 12.40 o'clock the morning of the 2d inst. two policemen observed flames shooting up from the rear of the Knickerbocker building on Tremont street, and at once gave alarm 53. It proved that the Edison electric light station on Head place, off Boylston street, was well on fire, and there was every indication that surrounding property was greatly endangered; indeed, when the firemen arrived the rear of the buildings on Tremont street and one on the opposite side of Head place had ignited. There was a hard fight, and the fire was soon under control, but not until the entire upper part of the Edison works was destroyed. The second floor was used as the dynamo room, and here the fire started in an equalizer box. John Gaffney and William Foster were in the room at the time, and so rapid was the spread of the flames that they barely escaped with their lives. N. H. Seavey, the engineer, was in the engine room on the floor below, and also had a narrow escape. In the dynamo room were fourteen dynamos, valued at $2,500 each. In the room beneath were seven engines, one for every two dynamos. In the front of the dynamo room was the office, and beneath was the meter room. The building in the rear contained the boiler rooms, repair shops, &c. The damage to the Edison works, including dynamos, machinery, belts, office and building, will reach about $50,000. The burning of the electric light station cut out this system from the entire city, both the overhead and the underground system being supplied from this station. The Globe Theatre, Hollis Street Theatre, Adams House, Clark's Hotel, Park's Hotel and Young Men's Christian Association buildings are lighted from this source, as are also numerous stores, halls, &c. Several elevators and engines are also stopped by lack of power. The management of the station were equal to the emergency, and immediately cleared the *debris* from the engine and boiler room, telegraphed for new dynamos, and within thirty-six hours were furnishing light again to their subscribers. This was energy and business, and reflects great credit upon those in charge.

BOSTON, June 16th, 1888.

. . . . The electricity is generated from the armature to the field. The current is produced by the velocity of the armature through the magnetic field that produces the current. The strength of the current is 20 amperes (amperes meaning quality), 17 volts (volts indicating the force).—*New Orleans Newspaper.*

CHICAGO.

Electric Service at the Republican Convention.—The Electric Lighting and Telegraphic Arrangements.—Conclusion of Argument in the Cushman Telephone Case.—Practical use of the Graphophone by one of the Court Stenographers.—Electric Club Notes.—Mr. Bliss on Alternating vs. Continuous Currents.—The Aldermen and the Local Press Seeking to Regulate the Chicago Telephone Co.—Damage from Lightning at Milwaukee.—Moderate Reduction of Telephone Rates at Joliet.—Mr. E. M. Barton, President of the Western Electric Co., takes a Vacation in Europe.—The "Rookery" Edison Lighting Plant.—The Sprague Electric Equipment Co.

A SPLENDID exhibition of electric lighting was given in the Auditorium building in which the Republican National Convention was held. About 3,000 incandescent lamps were employed, and the effect was extremely brilliant. The lights were arranged too with an unusual regard for artistic effect and decoration. The main ornamental feature was a shield made by the grouping of 500 incandescent lamps with red, white and blue globes. The effect was striking and brilliant; stars of electric lights were arranged on the ceiling and on the walls, and bunches of three lights were placed under the gallery rails. Current was furnished by two No. 32 Edison dynamos. Two Ide engines furnished the motive power. The telegraph facilities of the convention were such that 100,000 words could be handled hourly. The telegraph companies had about 50 wires run into the auditorium and about the same number of operators were at the desks. They were given plenty of room and were cared for in much better shape than usually at national conventions. The state delegations vied with each other in decorating their headquarters in the Grand Pacific hotel. To the Allison men, however, the honor of bearing off the palm belongs. By grouping a hundred or more incandescent lamps over the door of their headquarters the letters in the name of Iowa's favorite son blazed forth with startling brilliancy.

The most important event in electrical circles during the month was the closing of the suit of the Bell Telephone Co. and the Chicago Telephone Co. against the American Cushman Telephone Co. and others. The arguments which closed this important litigation were heard by Judge Blodgett in the United States Circuit Court. The addresses were made by five counsel, and five days was consumed in the hearing. Nothing particularly new was developed. Counsel on the one hand held that the testimony introduced by the defendants could not for a moment be considered as proof of the validity of the defendants priority of invention. The most that Dr. Cushman could have discovered, it was asserted, was the acoustic telephone. The attorneys for the defendants said this same testimony proved beyond all possibility of a doubt the defendants' claim, unless it was assumed that a score of witnesses had wilfully committed perjury. George L. Roberts, of Boston, made the opening argument for the Bell company. He reviewed the testimony in the case which fills several thousand pages. He instructed the court in all branches of telephony and closed with a statement that Dr. Cushman's action and testimony were characterized by inconsistency. His speech occupied two days. Judge C. D. T. Smith, of Chicago, followed with the opening argument for the defendants. He paid considerable attention to the "talking boxes" which it was alleged Dr. Cushman had used. He asserted with considerable confidence that they could be used practically, and he referred to the evidence of Professor Cross, one of the plaintiffs' experts, in proof of the statement. Benjamin F. Thurston, of Providence, made the next address for the Bell company. James L. High, of Chicago, spoke for the defendants, and Chauncey Smith, of Boston, closed the case for the plaintiff. The last-named gentleman spoke particularly of the failure of Cushman to patent his alleged invention and of the inferences which naturally followed from this neglect. It is hoped that a decision will be handed down not later than the middle of July.

One of the stenographers who reported the arguments brought with him from Washington two graphophones, which he uses continually in his work. The instruments are simple, and they reproduce sound with remarkable fidelity. The tests which were made with them are thought to demonstrate their usefulness satisfactorily.

At the first meeting in June of the Electric Club, George H. Bliss read the seventh paper on the "Alternating *vs.* the Continuous Current." He viewed the subject almost exclusively from a commercial point of view. His point in brief was this: The continuous current, by its success, had demonstrated its usefulness and its safety. It had brought in dividends to stockholders, and its history was such that it had created a presumption in its favor. On the advocates of the alternating system rested the burden of proof. On them devolved the duty of proving the superiority of their method of central station distribution. This proof Mr Bliss held had not yet been forthcoming; and it is safe to assert from the general tenor of his paper that he does not expect to find evidence which will be conclusive to him.

If they can find authority for doing so, the Chicago aldermen propose to follow the example of the St. Louis city council and make war on the Chicago Telephone company. The Chicago council is almost to a man opposed to the company and would enjoy nothing better than to reduce the telephone rates. The legal department of the city is engaged in consulting authorities to ascertain if the council has a right to adjust rates—a right hitherto supposed to be vested in the legislature. The local press is advocating the adoption of an ordinance charging the telephone company a license fee of $10 per year for each instrument. That would give the city a revenue of $40,000. It is said that the company is willing to pay a licensé fee of $5 for each telephone.

Milwaukee experienced a severe storm on June 14th. The lightning struck the telephone wires and burned out the Michigan street cable. The service was temporarily disabled. The police and fire alarm systems also suffered from the same cause.

Joliet has made a decided innovation. The telephone company has reduced the rates in that city to $54 for business houses and $36 for residences. The change entirely removes the dissatisfaction which has heretofore existed concerning charges.

Mr. E. M. Barton, president of the Western Electric Co., has left Chicago for an absence of some months in Europe.

The Edison plant in the Rookery, Chicago, is one of the largest isolated plants in the country. It consists of 4,500 lights. The current is furnished by four dynamos. The Rookery is the finest office building in Chicago, and the owners claim it is the most elegant in the world.

The Sprague Electrical Equipment Co., of Chicago, has been incorporated. The capital stock is $50,000. The company proposes to engage in construction work.

CHICAGO, June 22, 1888.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall street, New York city.*

GRAVITY BATTERY vs. DYNAMOS.

[94].—In reading Mr. Francis B. Crocker's interesting paper on "The Possibilities and Limitations of Chemical Generators of Electricity" appearing in the June number of the ELECTRICAL ENGINEER, I was almost lead into an error by the statements in the fifth paragraph on page 252, comparing gravity batteries to a dynamo. I do not wish to appear to correct Mr. Crocker, but only to keep some other readers of the article in question from an error into which I nearly fell. At first I understood that 1,500 gravity cells would give a useful output equal to one electrical horse-power; this is not meant, as in the case supposed there could be no external circuit and consequently all the work would be done in the battery itself. As I have never met with any statement as to the number of cells necessary to give a definite current with a given fall of potential, it has seemed to me interesting to find formulæ for the number of cells of any battery needful to supply any power. Let $C =$ current required; $E =$ E. M. F. at terminals; $e =$ E. M. F. of cell; $r =$ its resistance; $m =$ number of cells in parallel and $n =$ the same in series. Taking it for granted that the resistances within and without the battery should be equal, we have one mth of $n\,r$, or

$$\frac{n\,r}{m} = \frac{E}{C} \therefore m = n\frac{C\,r}{E} \text{ or substituting for } n \text{ its value } n = \frac{2\,E}{e}$$

$$\text{(because } E = \tfrac{1}{2}\,n\,e\text{)} \quad m = \frac{2\,C\,r}{e} \qquad (1)$$

$$\text{Now } C = \frac{n\,e}{\frac{n\,r}{m} + \frac{E}{C}} \text{ or } n = \frac{E\,m}{m\,e - C\,r} \qquad (2)$$

Suppose 10 lamps of 100 volts and .75 ampere are to be fed by gravity batteries whose constants are as given by Mr. Crocker, 1 volt and 2 amperes, then by (1) we have $m = 30$ and by (2) $n = 200$ or $m\,n = 6{,}000$. That is, it would require 6,000 ordinary gravity cells to give one electrical horse-power to an external circuit. Also a current of one ampere and 750 volts, and of 750 amperes and one volt, would require the same number differently arranged.

Of course the above example shows that it would be ridiculous to use gravity batteries for such use; but as the formulæ are general they can be applied to any cells.

Yours truly, DS.

WELDING RAILS BY ELECTRICTIY.

[95.] In the correspondents' column of the last issue of the ELECTRICAL ENGINEER, Mr. Otis K. Stuart takes advantage of an extract on the above subject that appeared in the May number, to criticise my method of electrically welding and tempering metals as applied to the construction of railway lines. In this article he attempts to show, among other things, first, that the welding of steel rails in the manner proposed by me is practically impossible, and secondly, that the difficulties in the way of successfully operating a road provided with continuous rail sections 1,000 feet in length, such as those arising from expansion and contraction, etc., are such as to render the "scheme" entirely impracticable.

Before replying to this criticism in detail, it will be necessary for me to digress somewhat in order that your readers may better understand the situation. It will be evident from a perusal of his letter that Mr. Stuart imagines that, because he fails to understand a new process, or because the description thereof is not sufficiently explicit to enable him to comprehend it, the inventor of the process is either a crank or is totally unacquainted with the subject upon which his process is based. In contradistinction to this assumed lack of knowledge on the part of the inventor, Mr. Stuart himself, undertakes to speak in an authoritative manner not only upon the subject of electric welding, but, to judge from his closing paragraph, upon electrical matters in general. In addition, he would seem to be gifted with the rare faculty of distinguishing between what invention will and what will not be a success, without exercising the preliminary formality of inquiring into the features or details of the subject upon which he so freely expresses his opinion. Had Mr. Stuart taken the pains to acquaint himself with the essential details of the system that he is apparently so anxious to condemn, instead of jumping at conclusions from a mere newspaper extract, he would at once have become aware that his alleged "difficulties" had no foundation in fact, or were provided for and successfully overcome long before his effort to formulate them was written.

To those who are aware of Mr. Stuart's connection with the Thomson Electric Welding Co. it may not be a matter of much surprise that he should endeavor to attack a rival system, especially when this system contains features that are absolutely essential to the successful operation and the commercial development of the system with which he is identified. Personally, however, I was not only much amused at the nature of the objections raised in the letter under notice, but considerably surprised to find that they emanated from Mr. Stuart.

The source of my surprise may be understood from the fact that about one month *after* the issue of my patent (No. 370,282, granted September 20th, 1887), for this process of welding and laying railway tracks and other continuous sections, and for the method of electric welding and tempering involved therein, an application for letters patent was filed by Professor Elihu Thomson, to which were appended *exact duplicates* of several of my broad method claims, and with this application was filed an affidavit and petition signed by Professor Thomson, praying that such application be put into interference with my patent. This interference has since been declared, and the contest for priority of invention on the methods involved is now pending between us.

In view of the above facts, I cannot but conclude that Mr. Stuart, in his ardor and zeal to advance the interest of Professor Thomson, has, without consulting with his superior, heedlessly rushed into print to criticise on general principles a system with the details of which he is entirely unacquainted. I believe I am correct in drawing this inference, since it is apparent that Professor Thomson would not be so injudicious as to attempt to prove the impracticability of a "scheme" which he is striving his utmost to obtain possession of, unless, indeed, he has already arrived at the conclusion that there is nothing to be gained by him in continuing the contest now pending before the Examiner of Interferences in the Patent Office.

Having thus presented the facts of the situation to the reader, I will now consider the objections advanced by Mr. Stuart.

Mr. Stuart's first objection is that the joints and adjacent parts of the rail could not be tempered equally with the other parts of the track. This may be true with regard to the peculiar tempering process or processes, if any, heretofore practiced by him. If Mr. Stuart will glance at a copy of the patent above referred to, describing this method of welding and laying railway tracks, he will find, among other things, the two following claims, which not only describe the method by which a uniform temper *is* produced, but which cover *broadly* the art of electric welding in which the current strength is gradually increased to prevent burning the metal or permanently destroying its tempering qualities at the joint, to wit:—

"2. The herein described method of welding together two metals of hardened or tempered structure without destroying their respective retempering properties at the point of union, which consists in passing an electric current of heavy heating effect through the ends in contact and gradually increasing the current strength until they reach a fusing temperature, as described."

"4. The herein described method of effecting a hardened or tempered junction between two metals of similar density and like cross-section, which consists, first, in welding the ends in contact by the passage of an electric current or currents therethrough, and secondly, *in reheating the said joint* and applying a suitable tempering compound when the joint has reached the desired degree of heat for tempering."

A question that seems to present insurmountable difficulties to the mind of my esteemed critic, is that of providing for the "enormous amount of expansion and contraction in rail lengths of 1,000 feet." If the solution of this problem were entrusted to the hands of Mr. Stuart, there would, indeed, be reason to fear for the result. Fortunately, however, for the safety of the future traveling public, I am able to state that this question has been solved in such a manner that not only can none of the disastrous results predicted by Mr. Stuart possibly occur, but a railway of this description is far more safe, economical in construction and maintenance, and more conducive to speed and the pleasures of travel than the ordinary railway lines with their innumerable joints, fish plates, nut locks, etc., can ever be made, to say nothing of the immense saving in cost of repairs to rolling stock and road bed that the absence of rail joints will effect.

The co-efficient of expansion per degree Fahr., according to the best authority, is, for steel, .0000066. A steel rail 1,000 feet in length would, therefore, expand or contract .792 inch for each 10 degrees variation in temperature, instead of 1.5 inches as stated by Mr. Stuart. Allowing a maximum range of temperature of 150 degrees Fahr., we have a total expansion and contraction of 11.88 inches, or something less than one foot, to provide for in our expansion joints in a length of 1,000 feet. Now, inasmuch as each thousand foot length is rigidly secured at its centre, it can only expand toward or contract from both ends, and, therefore, the maximum movement *at its extremities* within the entire range of temperature above stated can never exceed six inches. It must, moreover, be borne in mind that there will be required a variation in temperature of 25 degrees to produce a movement of *one inch* at the extremities of each rail section, and that this is above the usual

Fig. 1.

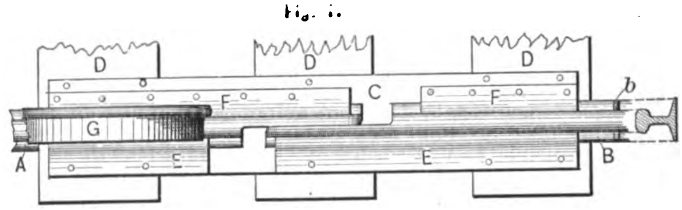


Fig. 3.

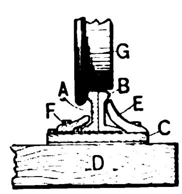

Fig. 2.

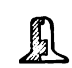

Fig. 4.

maximum variation in temperature within the limits of a day of 24 hours. This small amount of to-and-fro movement or "creep" in each rail section daily, assisted as it is by the passage of trains over the road, is scarcely perceptible, and even on roads where the rails are secured by the ordinary rail spikes, can be allowed without detriment. Preferably, however, I employ a slightly modified form of spike or rail fastening that is equally simple and permits of free longitudinal motion, while at the same time it holds the rail with the utmost security against lateral displacement. It is scarcely necessary to add that the "buckling," "ruptures" and other difficulties prophesied by Mr. Stuart, have absolutely no material existence in this connection, nor can such phenomena find place anywhere except perhaps, in his own imagination.

The variation in the length of each rail section is compensated for by divided expansion joints so arranged that there is no interruption or break in the bearing surface of the rails throughout the entire track, the latter being practically continuous and entirely free from the objections incident to the use of the ordinary rail joints. These expansion joints are located at intervals of 1,000 feet on substantially straight and level portions of the road (or any other distance apart that may be desirable), and in the case of curves, are located on the straight portions of the track a short distance before and beyond the curve respectively, the comparatively short curved section being rigidly secured at its centre and expanding in both directions in the same manner as the straight sections.

The construction of the expansion joints will be understood from the annexed plan and elevation, figures 1 and 2. A, B, represent respectively the divided extremity of each rail section, as they are held in alignment upon a bed plate, C, secured to the

cross-ties, D. The bed-plate, C, is provided with fixed guides, EE, and adjustable guides, FF, between which the rails are free to move in a longitudinal direction. The end pieces, A, B, of each section are preferably made of aluminum steel, to increase their strength; and each half of the divided joint is tested to support without deflection a load several times that of the greatest weight they are ever called upon to bear in practice. The extreme ends of the rails are slightly inclined, and as the tread of the wheels is broader than the head of the rail, and the whole arrangement supported upon a solid unyielding plate, the transit from one rail section to the next is made without the slightest perceptible shock or jar.

It should be further stated that in forming a rail section by the process of electrically welding the ordinary rail lengths together, the joint produced between two successive lengths is preferably provided with a rib between the head and flange, as shown in figure 3, and at *b* in figure 1. This insures a greater degree of strength at the juncture, and renders the entire roadbed smooth, safe and substantial. A modified form of divided joint is illustrated in figure 4.

As to Mr. Stuart's remaining criticisms, I can only repeat that it would speak much better for Mr. Stuart's "familiarity" with the subject if he but took the pains to find out what has already been done in this field before venturing his predictions as to what has *not* been accomplished. A man is not likely to build himself a house without providing some means of getting into and out of the same, nor am I likely to build a line of railway without providing means for renewing worn portions of the track when necessary. This, I may state for the satisfaction of Mr. Stuart, has been accomplished in such a way as to permit of rapidly cutting out the condemned portion and welding on a new length *in situ*, without loosening or disturbing the rails on either side and without interfering with traffic, by means of a special process and mechanism devised for this purpose. It may be stated, however, that owing to the absence of the severe pounding or hammering action that occurs at the joints of all ordinary roads as at present constructed, the tendency to wear in the continuous rails will not only be uniform, but the life of the rails will, in all probability, be three or four times what it is at present. This will be appreciated when it is understood that there are generally 176 interrupted joints to the mile for each rail, as against five divided joints in this system.

In conclusion, I wish to state that before very long Mr. Stuart will have the opportunity of seeing a line of railway constructed upon this principle and in successful operation, and will then have a chance to reflect that it is his theories, and not the "plans" to which they are directed, that have proven themselves commercially impracticable and visionary.

Very respectfully

ELIAS E. RIES.

LITERATURE.

REVIEWS.

Dynamo Tenders Hand Book: BY F. B. BADT. Chicago: Western Electrician Co.; 100 pages, 70 illustrations, flexible cloth. Price, $1.00.

THIS manual—now some three months before the interested public—has, we understand, been well received in electric light and power circles.

In his preface Mr. Badt says he "has striven to lay down, as the results of an extended experience, general rules for the care and operation of electric light installations, and discarding entirely the use of technical phraseology and scientific terms and formulæ, has endeavored to confine his use of words to those very plain, simple and elementary in character."

A book of this kind was much needed, inasmuch as the rapid growth of electric lighting as an industry has necessasily called into its service large numbers of employés having no previous acquaintance with electrical machinery of any kind. The many volumes already existing that treat of electric lighting or other applications of dynamic electricity, scarcely touch the line of instruction which makes up the greater part of Mr. Badt's handy volume. Lampmen, linemen and all other employés of electric light stations, as well as dynamo tenders, will find much useful information in small compass in this little book, which is small enough for the coat pocket. The directions given are plain, simple, even obvious, one would think to any fairly intelligent man in electric lighting service; but so long as plain and obvious things escape ordinary observation, as they usually seem to, somebody must call attention to them. Such work is particularly important, when ignorance or failure to recognize and observe ordinary precautions endangers life and property, as it does in electric service.

American Street Railways, their Construction, Equipment and Maintenance: BY AUGUSTUS W. WRIGHT. Consulting Engineer, Member A. S. C. E., etc. Chicago: Rand, McNally & Co., 1888.

MR. Wright's high reputation as a street railway engineer would of itself be a sufficient guarantee of the quality of any work on the subject of the volume under notice from his pen. The general public is very apt to regard horse-railroads as in the category of very simple undertakings. Daily familiarity with them and use of them obscures from general observation the perplexing and rather difficult engineering and administrative problems involved in their commodious and successful operation. General readers would doubtless be surprised by a glance through Mr. Wright's book, to note the large number of technical, economic, and administrative questions that demand careful consideration by the street railway engineer. Under the several chapter headings—Construction—Paving—Track Cleaning—Equipment—Buildings for Street Railways and Management of Street Railways,—Mr. Wright treats the subject comprehensively and with fullness of detail. The treatise is practically confined to horse-railroads. To this, of course, no objection can be made, for notwithstanding the introduction of the cable and the electric motor, horses are still the general reliance for motive power. But these new methods of traction are coming to the front so rapidly for street traffic, that a treatise on American Street Railways, dated 1888, might fairly be expected to have something more to say about them than the bare allusion in Mr. Wright's appendix.

The publishers have done more than well in the convenient size and shape of the book, its handsome paper and type and its substantial and tasteful binding. The volume is well illustrated. It is a pity to find any fault with the make-up of a book so convenient and pretty, but its convenience would have been enhanced by running chapter-headings in place of the general title, on every alternate page.

RECENT PUBLICATIONS

American Patent Cases. A collection of patent cases criticised, explained, overruled, or otherwise limited by subsequent decisions of the Federal Courts, giving a short statement of the point criticised. By Simon G. Croswell, editor of the fourteenth edition of "Greenleaf on Evidence." 12mo., sheep. 286 pages. Price $3.00 net. Boston, Little, Brown & Co., publishers.

Revista do Club de Engenharia, Anno 1—Vols. iv., v. and vi.—Abril, Maio, Junho, 1887. Rio de Janeiro.

CATALOGUES AND PAMPHLETS RECEIVED.

Under the title Elettricita Teorico-Pratica we have received the catalogue and price list of the Società Elettrica Industriale Franco-Italiana of Milan, a handsome pamphlet of 128 pages, very copiously illustrated and fully indexed. The lists and illustrations comprise nearly everything pertaining to modern applications of electricity, from school apparatus and toys to dynamos and transformers.

The Woodhouse & Rawson Electric Supply Co. of Great Britain (Limited), of London, England, issue a catalogue of domestic electrical supplies of a more than usually elaborate and comprehensive character. It is not unlikely that many American manufacturers and dealers would find some objects of interest in this well illustrated list. We are used to considering ourselves ahead of all the rest of the world in electrical applications as well as in most other things. It is well now and then to look about a bit and see what others are doing. The catalogue of the Woodhouse & Rawson company indicates that domestic electric service is both elaborate and extensive in Great Britain.

The Writing Telegraph, that very interesting recent development of telegraphy, is quite fully described and illustrated in a small pamphlet published a short time ago by the Writing Telegraph Company of New York. Many of our readers will remember seeing the system of Mr. Robertson in operation at the electrical exhibition of the American Institute fair last autumn. The general office of the company is at 57 Murray street, New York.

The Bentley-Knight Electric Railway Co.'s latest circular announces the claim of that company to "control all practical methods of operating electrically equipped cars by means of conductors contained in and protected by subsurface conduits." Very handsome illustrations are given of their fully equipped trucks, of cars, and of some details of construction. Estimates are given of construction and equipment, and of running expenses for a double track, five mile, 40 car road for horse, electric and cable traction. The comparative figures are much to the advantage of electricity. The Bentley-Knight company were early in the field, and have worked out a full system of electric street railway.

Advertising circulars and pamphlets are more and more enlisting the services of artistic designers and printers, till they vie with Christmas and Easter cards in beauty and elegance.

We have seldom seen a handsomer circular than that recently issued by the Ansonia Brass and Copper Company, containing testimonials to the good qualities of the Cowles' patented fire proof and weather proof line wire. The Ansonia Company was one of the first of the large brass and copper companies to realize the prospective large consumption of insulated wires, and to prepare themselves to meet it directly, by establishing a plant of insulating machinery.

The Effect of Magnetism in Watches.—How to prevent it—a pamphlet of 14 pages, published by the Geneva Non-Magnetic Watch Co., New York, consists of a paper by Mr. C. C. Haskins, of Chicago, prepared for the convention of the Brotherhood of Locomotive Engineers at Chicago, in October, 1887. The timeliness of the subject is sufficiently evident from the very considerable attention it has received in the discussions of electrical societies and in technical journals. Mr. Haskins treats the topic in his usual practical common-sense way, and his essay will be found of interest to all who are anxious about their time pieces.

The Electro-Automatic Transit Company, Baltimore, Md., issue a prospectus setting forth a scheme of electric telpherage, giving pictorial illustrations of tracks and carriages, and some estimates of construction and operation. The company claims to "control the patents, under this system, for the United

States and all the principal countries of the world." "It is now ready to receive overtures or propositions for the formation of companies and the building of roads under said patents." It is not "said," however, what patents are controlled. The circular is fortified and embellished by the following quotations:

"'Tis not in mortals to *demand* success,
But we'll do more * * * We'll *deserve* it," and

"There are more things in heaven and earth * * * than are dreamed of in your philosophy."

The first of these is certainly most praiseworthy.

ELECTRICAL NEWS AND NOTES.

THE COURT OF PATENT APPEALS BILL.

Below we print the bill proposed by the National Electric Light Association to create a court of patent appeals, as amended by Mr. Justice Bradley and Mr. Justice Miller, both of whom have given it careful attention; also letters approving the bill, from the late Chief Justice Waite, Justices Bradley and Miller, the Commissioner of Patents and the Patent Bar Association of Washington. In the House of Representatives the bill has been read twice, referred to the Judiciary Committee and ordered printed.

A BILL

To establish a Court of Patent Appeals of the United States.

BE IT ENACTED *by the Senate and House of Representatives in Congress assembled:*

SEC. 1. There shall be a Court of Patent Appeals of the United States, which shall consist of a Chief Justice and four Associate Justices, who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall hold office during good behavior. Any three of said Justices shall constitute a quorum.

SEC. 2. The Associate Justices shall take precedence according to the dates of their commission, or when the date of the commission of two or more of them is the same, according to their ages.

SEC. 3. In case of a vacancy in the office of Chief Justice, or of his inability to perform the duties and powers of his office, they shall devolve upon the Associate Justice, who is first in precedent, until such disability is removed, or another Chief Justice is appointed and duly qualified. This provision shall apply to every Associate Justice who succeeds to the office of Chief Justice.

SEC. 4. The Justices of the Court of Patent Appeals shall receive the sum of eight thousand dollars each per annum, to be paid monthly.

SEC. 5. The Court of Patent Appeals shall have power to appoint a Clerk and a Marshal for said Court, and a Reporter of its decisions.

SEC. 6. One or more deputies to the Clerk of the Court of Patent Appeals may be appointed by the Court on application of the Clerk, and may be removed at the pleasure of the Court. In the case of the death of the Clerk, his deputy or deputies, shall, unless removed, continue in office and perform the duties of the Clerk in his name until a clerk is appointed and qualified; and for the default or misfeasance in office of any such deputy, whether in the life-time of the Clerk or after his death, the Clerk and his estate and the sureties on his official bonds shall be liable, and his executors and administrators shall have such remedy for such default or misfeasance committed after his death, as the Clerk would be entitled to if the same had occurred during his life-time. The fees of the Clerk shall be the same as those of the Clerk of the Supreme Court for like services, but shall not exceed six thousand dollars per annum; the residue to be accounted for to the treasury of the United States. The salaries of the deputy clerks shall be fixed by the Court in no case to exceed twenty-four hundred dollars per annum.

SEC. 7. The Marshal shall be entitled to receive a salary at the rate of two thousand dollars a year. He shall attend the Court at its sessions, shall serve and execute all process and orders issuing from it, or made by the Chief Justice or an Associate Justice in pursuance of law, and shall take charge of all the property of the United States used by the Court or its members. With the approval of the Chief Justice he may appoint assistants and messengers to attend the Court, with the compensation allowed to officers of the House of Representatives of similar grade.

SEC. 8. The Reporter shall cause the decisions of the Court of Patent Appeals, made during his office to be printed and published within six months after they are made, and within the same time, shall deliver three hundred copies of the volumes of said report to the Attorney-General. And he shall, in any year when he is so directed by the Court, cause to be printed and published a second volume of said decisions, of which he shall deliver in like manner and time, three hundred copies.

SEC. 9. The Reporter shall be entitled to receive from the treasury an annual salary of twenty-five hundred dollars, when his report of said decisions constitutes one volume, and an additional sum of fifteen hundred dollars when, by direction of the Court, he causes to be printed and published in any year a second volume. But said salary and compensation respectively shall be paid only when he causes such decisions to be printed, published and delivered within the time and in the manner prescribed by law, and upon the conditions that the volumes of said report shall be sold by him to the public for a price not exceeding four dollars a volume.

SEC. 10. The three hundred copies of the reports of the Court of Patent Appeals shall be distributed by the Attorney-General as follows: To the Commissioner of Patents forty copies, and the balance as provided in the section 683 of the Revised Statutes for the distribution of the Supreme Court reports.

SEC. 11. The Court of Patent Appeals shall hold at the seat of government one term annually, commencing on the second Monday in October, and such adjourned or special term as it may find necessary for the despatch of business.

SEC. 12. If at any session of the Court of Patent Appeals a quorum does not attend on the day appointed for holding it, the Justices who do attend may adjourn the Court from day to day for twenty days after said appointed time, unless there be sooner a quorum. If a quorum does not attend within said twenty days, the business of the Court shall be continued over until the next appointed session; and if during a term, after a quorum has assembled, less than that number attend on any day, the Justices attending may adjourn the Court from day to day until there is a quorum, or may adjourn without day.

SEC. 13. The Justices attending at any term when less than a quorum is present, may, within twenty days mentioned in the preceding section, make all necessary orders touching any suit, proceeding or process, depending in or returned to the Court, preparatory to the hearing, trial or decision thereof.

SEC. 14. The Court of Patent Appeals of the United States shall have appellate jurisdiction in the cases hereafter specially provided for without regard to the sum in controversy.

1. "From the Courts of the United States having original jurisdiction of cases touching patents, copyrights, trade-marks and labels, in all cases involving these subjects."

2. From the Commissioner of Patents in all cases touching the patentability of inventions, priority of invention among several claimants for patent upon the same invention, and in all cases of re-issue and the judicial practice of the Patent Office, also all cases touching the registration of trade marks or labels and the rights of conflicting claimants therefor.

SEC. 15. From and after the passage of this Act, there shall be no appeal from the Circuit Courts of the United States or any territorial or district Court or Court of the District of Columbia, in cases touching patents, trade-marks, copyrights or labels, to the Supreme Court of the United States directly, but all such cases formerly appealable to the Supreme Court shall be heard on appeal by the Court of Patent Appeals.

SEC. 16. There shall be a right of Appeal from the Court of Patent Appeals to the Supreme Court of the United States in all cases regardless of the amount in controversy; subject to the same regulations, however, as now exist with regard to appeals to the Supreme Court in causes of Admiralty and Maritime jurisdiction, and to such further regulations as the Supreme Court of the United States may make.

SEC. 17. All cases touching patents, trade-marks, copyrights or labels, now pending before the Supreme Court of the United States awaiting trial shall be transferred to and heard by the Court of Patent Appeals.

SEC. 18. When any Judge of the Court of Patent Appeals resigns his office after having held his commission as such, at least ten years, or who has held his commission as such for not less than five years, having previously held a commission as a Judge of Circuit or District Court of the United States for a period sufficiently long to make up ten years' service as a Judge of a United States Court, and having attained the age of seventy years, he shall, during the residue of his natural life, receive the same salary which was by law payable to him at the time of his resignation.

SEC. 19. Section four thousand nine hundred and eleven of the Revised Statutes shall be, and hereby is amended so as to read as follows: If such party is dissatisfied with the decision of the Commission he may appeal to the Court of Patent Appeals of the United States.

SEC. 20. Section four thousand nine hundred and twelve of the Revised Statutes shall be, and hereby is amended so as to read as follows: When an appeal is taken to the Court of Patent Appeals the appellatee shall give notice thereof to the Commissioner, and file in the Patent Office, within such time as the Commissioner shall appoint, his reasons of appeal, specifically set forth in writing.

SEC. 21. That section forty-nine hundred and fifteen of the Revised Statutes of the United States is hereby repealed.

SEC. 22. That section seven hundred and eighty of the Revised Statutes relating to the District of Columbia is hereby repealed.

SEC. 23. All Acts or parts of Acts inconsistent with the provisions of this Act are hereby amended so as to be consistent therewith.

Approval of Justices of the Supreme Court of the United States.

Supreme Court of the United States,
Washington, May 25th, 1888.

Hon. George Ticknor Curtis,
My Dear Sir :

It gives me pleasure to say, that, after going over the Bill of the H. of R. No. 9084, to establish a Court of Patent Appeals, and making a few suggestions which you accepted, I approve of the Bill entirely. It will do much to relieve the overburdened docket of our Supreme Court in a direction where it can best be done.

Although the Bill has been submitted to no distinct vote of the members of the Court, it has been considered by them all, and I feel sure that I express their concurrent opinion when I say, that they all desire the passage of the Bill, and will be much gratified if it shall become a law.

I am very truly yours, SAM'L F. MILLER.

Supreme Court of the United States.

Washington, April 9, 1888.

Arthur Steuart, Esq.,
Dear Sir :

Your Bill (H. R. 9084) would make a great improvement in this department of Judicial procedure.

Very truly yours, JOSEPH P. BRADLEY.

Letter from the late Chief Justice Waite to Mr. Geo. Ticknor Curtis.

Washington, March 16, 1888.

My Dear Mr. Curtis :

I have read carefully your letter to Mr. Gorman, a copy of which some one has been good enough to send me, and agree with you cordially in all your suggestions, but especially that which relates to the finding of facts by the Court of Patent Appeals. There is no more reason why the facts should come before us in this class of cases after the trials below, than there is in cases of Admiralty.

Sincerely yours, M. R. WAITE.

Opinion of the Commissioner of Patents.

U. S. Patent Office,
Washington, D. C., May 26th, 1888.

Arthur Steuart, Esq.,
Baltimore, Md.,
Dear Sir ,

I have considered the Bill, H. R. 9084, with amendments suggested before sub-committee of Judiciary Committee of the House, and am convinced that it meets the urgent requirements of the present situation. It will tend directly and immediately to relieve the Supreme Court of its enormously overgrown docket, and to abolish the delays in the administration of law which now almost amount to a denial of justice. The patent laws in their application must be applied by expert tribunals. The Patent Office is an Expert in the Arts. It is required to be such, not only by the nature of its duties, but by the principles of its organization. It is impossible that judicial tribunals can properly and safely revise and review its work, and adjudge the rights of the public and of individuals arising from its operations, without possessing an element of the knowledge and familiarity of the expert that lies at the foundation of the whole system.

I sincerely trust Congress can be induced to give the subject the consideration it is worthy of.

Yours very truly, BENTON J. HALL.
Commissioner of Patents.

Opinion of the Bar.

Washington, D. C., May 22, 1888.

The Patent Bar Association of the District of Columbia is strongly in favor of a Court of Patent Appeals, such as is proposed by Bill H. R. 9084. We are clearly of the opinion that such a Court would be of vast importance.

First: By securing a far more uniform practice in the granting of patents, by which there would be less invalid patents granted, and the capital invested in patents and business enterprises based upon patents would be rendered more secure.

Second : It would lessen litigation, and what is equally, if not more important, it would enable patent cases to be decided in much less time.

Third : It would relieve the Supreme Court, for very few cases would ever go beyond the proposed Court.

Fourth : It would put an end to the conflicting decisions which is one of the great troubles of the day.

W. C. DODGE,
President Patent Bar Association.

THE WESTERN ELECTRIC COMPANY'S SINGLE CORD MULTIPLE SWITCH-BOARD FOR TELEPHONE EXCHANGES.

One of the most radical improvements recently made in the multiple switch-board for telephone exchanges is the so-called "single cord multiple."

The first board of this kind for practical use was installed some six months ago at the Eighth and Freeman street exchange of the City and Suburban Telegraph Association of Cincinnati. The board was arranged for 800 lines, and at present consists of five sections with 100 lines to each section. A board similar to this has also been in use a short time at Providence, R. I, and new ones are being installed at Brooklyn and Buffalo.

The advantage gained by the single cord system is the immediate answer which is given to the subscriber on receipt of his call. The operator picks up the plug to which the line of the calling subscriber is connected, and the head telephone is then in circuit with the subscriber. The operator seems to know which plug to reach for on the fall of a drop without any hesitation, just as a typewriter operator or piano player reaches for the right key. Tests were recently made with a stop watch, giving the time to fifths of a second.

These tests show the time from the fall of the annunciator drop to taking up the plug as one second; the getting of the number wanted from the subscriber who calls, when the subscriber gives the number promptly, as one second ; testing and inserting the plug as one second ; ringing and pushing in the key to disconnect the operator's telephone and restoring the drop as one and one-fifth seconds, making a total of four and one-fifth seconds.

The time required for disconnection, from the fall of a drop to getting the head telephone in circuit for listening is one second, and for taking off the connection is one and one-fifth seconds, making a total, for a connection and disconnection, of six and two-fifth seconds. This was found to be an average of a great many calls. In some cases the operators do better.

The quickness with which the operators make the connections and disconnections keeps them ahead of their work, so there is but little trouble from several calls coming in in quick succession.

If the subscriber would make no delay in announcing the number wanted, and if there were lines enough for each section to give the operators all the work they could do, by working with both hands and letting the connections lap over each other, they could make an easy average of six seconds for a complete connection and disconnection, which would be ten for a minute and six hundred for an hour, which is nearly three times the maximum work of an operator in any exchange where a count has been made.

The board has given excellent satisfaction. The superintendent of exchanges, of Cincinnati, writes :

"In operating the single cord multiple, the advantages gained over the double cord are that it requires only half the motions to complete connections between subscribers. To illustrate : On the single cord ten motions of the arm are necessary to answer, connect and disconnect ; on the double cord it takes eighteen. In detail, they are, single cord to answer, two motions ; double cord, four ; single cord, to connect, four motions ; double cord, seven; single cord, to disconnect, four motions ; double cord, seven.

"Our experience with the switch-board has been satisfactory, as it lessens the time and labor for each connection nearly one-half."

THE BOSTON ELECTRIC CLUB'S ANNIVERSARY.

On Thursday, June 21, the Boston Electric Club celebrated its first anniversary. The day was made the occasion for entertainment and hospitality in the true whole-souled Boston manner. The doors of the pleasant apartments of the club were thrown open at one o'clock for the reception of the members and invited guests, and when a large number had gathered, President P. H. Alexander made an address of welcome. He briefly described the growth of the club from a membership of 19 at its formation a year ago to 250 at the present time, and pointed out the advantages of the organization in bringing into fraternal relations the representatives of competing electric companies with the resulting gain to common interests attendant upon an interchange of ideas and experiences. Mr. Alexander hoped that the social and educational features of the club would attract new members, and sustain the interest and secure the attendance and hearty co-operation of the present membership during the ensuing year.

Mr. T. A. Edison and Mr. Gilliland were expected to be present and to exhibit the phonograph. A letter of regret was received from Mr. Edison, in which he stated that the phonograph was not yet perfected, and that when it should be first exhibited publicly it would be at the Boston Electric Club.

During the afternoon reception, a light lunch was spread in the parlors. Several pleasant hours were spent in social intercourse, greatly promoted by the toothsome luncheon and fraternal cigars till 4;30 o'clock, when the members and guests took the steamer "Nantucket" for Nantasket to enjoy a dinner at the Rockland house. About 150 gentlemen sat down to meat, drink and smoke, after which carnal but innocent pleasure the flow of talk began.

After brief remarks by the president, Mr. Alexander, addresses were made by Mr. Allan V. Garratt, Mr. Frank Ridlon, Mr. T Commerford Martin, Mr. C. W. Price, Mr. Prescott of the Boston *Globe*, Mr. A. J. De Camp, Col. Ransom, and others. Letters of regret were read from Moses G. Farmer, Thos. A. Edison, and others, who were unable to be present. At 9.30 o'clock the company took train for Boston, well pleased with themselves, and better pleased with the Boston Electric Club.

MOTORS FOR SMALL POWERS IN CHICAGO.

In the issue of the *Western Electrician* of February 4th, the fact was chronicled that the first small motor for power purposes run from an arc circuit of the Chicago Arc Light and Power Company, was in operation in Chicago, and the opinion was expressed that the prospects for an extensive use of motors were very bright. Last week saw an order recorded for the twenty-eighth Baxter motor for use in this city. The Chicago office of the Baxter Electric Manufacturing and Motor Company, W. W. Munro, manager, was opened for business ten weeks ago, and the motors ordered of them have all been ordered during that time.

In Chicago, motors are used in blank book, clothing, cloak, dress trimming, electric appliance, exhaust fan, hat and cap,

leather, truss, shirt, vest, and ventilator manufactories, book binderies, to run coffee mills, exhaust fans, lithographing and printing establishments, by publishers, lapidaries and opticians.

In company with Frank L. Perry, electrician of the western department of this company, who installed all the motors in Chicago, a *Western Electrician* representative made a tour of investigation. The first motor seen was in the shop of Chas. Essig, a lapidary on State street, who was found busily grinding stones of all manner of description. Mr. Essig is in a building in which there is no power, and is located on the top floor. He is eminently well pleased with the operation of his half horse-power motor. A printing establishment run by a 2 h. p. motor was next visited. Several small presses and a paper cutter were in operation, and here, too, great satisfaction was expressed with the operation of the motor.

In the shop of the Western Leather Manufacturing Co. there was a 1 h. p. motor operating three sewing machines, a strap puncher, two wax thread machines and a harness-creasing machine. The foreman and the girls, who had formerly run the machines by foot power, were equally loud in their expressions of delight—the foreman because on certain classes of work at least two-thirds more was accomplished in a day's time than under the old method, and the girls because they could accomplish so much more work at greater ease to themselves.

In each of the cases the automatic regulation of the motors was perfect.

In this connection a comparative schedule of charges for current for small motors in Chicago and several other cities will be of interest.—*Western Electrician.*

Schedule of charges per month in dollars for current for small motors.

THE TELEPHONE.

The executive committee has decided that the next meeting of the National Telephone Exchange Association, which will be held in the city of New York, shall commence on Tuesday, September 4th, 1888. Further details of the arrangements will be announced from time to time as they are perfected.

The Ohio Valley Telephone Co. is laying pipes from the rear of the Telephone Exchange, on Green street, to Eighth and Main streets, Louisville, Ky. The company will place all the wires in the central part of the city underground, doing away with a great many telephone poles. The business of the company has increased so materially during the past few years that the present poles are almost inadequate to sustain their weight.

In the settlement of the telephone difficulties of Rochester, N. Y., an advance is agreed upon of about 10 per cent., upon rates prevailing before the "strike." The permission to occupy the streets and public places for poles or underground conduits is given. In alluding to this settlement in our last number, the following important point, which will interest all telephone companies, was not stated. The company agrees to do one-half mile of underground work each year until three miles are completed and the subscribers agree to pay 50 cents per annum additional for each half-mile of conduit laid until two miles are in use, thus increasing their rate $2.00 per annum on account of underground work. Subscribers are returning rapidly, and the company is installing multiple switch-boards with a view to the improvement of the service.

Telephone exchange statistics from the circular of the American Bell Telephone Co., May 1, 1888.

	Schedule A		Schedule B		Schedule C		Schedule D		Total. Comparative statement for three years.		
	Population over 150,000.		Population from 50,000 to 150,000.		Population from 10,000 to 50,000.		Population of 10,000 and under.

The entire number of offices in the exchange systems, in operation January 1, 1888, was 1,191.

The much vaunted Van Rysselberghe system has at last been abandoned on the Swiss lines between Geneva and Lausanne and between Zurich and Bale, where independent telephone lines will henceforth be employed. The system seems to have come far short of the expectations of its promoters in both efficiency and economy. Dr. Rothen, co-director of the Swiss telegraphs is reported as saying :—

"The Rysselberghe system has certain weak points. The apparatus is especially delicate, particularly the condensers. A relatively slight atmospheric discharge may destroy them completely. It has, therefore, been necessary to apply lightning rods which can transmit the atmospheric discharges more easily than the condensers; but then these rods easily become deranged, as a slight atmospheric discharge may put the telegraphic line in communication with the earth, and, in spite of the great sensitiveness of the lightning rods, the condensers are sometimes destroyed. The Rysselberghe system affects the telegraphic service in an annoying manner. At the outset it is necessary to increase the batteries of the telegraphic stations considerably; but a worse point is that the telegraphic service is delayed by the increased duration of the variable state of the currents. The Morse service generally does not suffer, but the transmission on the Hughes system is often deranged, and the service of the rapid apparatus, such as the Wheatstone, is probably impossible.

"From a telephonic point of view, the transmissions are very faint, at least with ordinary apparatus, and the silence of the telegraphic signals is, so to speak, obtained only in theory.

"The cost of the installation of the system is not so trifling as it is sometimes believed. Its application on the telegraphic line from Geneva to Lausanne cost about 15,000 francs."

At St. Louis the Missouri Bell Telephone Co. was early in June a defendant in a case in the police court for violating the ordinance prohibiting telephone companies from charging more than $50 a year for use of an instrument. Judge Cady held that the ordinance was legal and all right, and fined the telephone company $300. The directors of the St. Louis Bell Telephone Co. refuse to make any new contracts; as contracts expire at the rate of about a dozen each day, a dead-lock in the telephone service is threatened. The company promptly removed twelve telephones from the municipal departments. The mayor threatens to chop down the poles and wires while the company defies him, claiming to derive its privilege from the state.

At Hopkinton, Mass., on the 24th of May, the telephone switch-board was burned out and completely ruined by the wires getting crossed with an electric light wire.

At Washington, the National House of Representatives has

made an appropriation of $36,000 for putting the District telegraph and telephone wires underground. On June 13th the senate concurred, with an amendment striking out the clause which required all telephone and telegraph and other wires to be removed from the streets, wherever the District wires shall have been removed. The bill now goes back to the house, to see whether that body will agree to the striking out of this provision.

ELECTRIC LIGHT AND POWER.

OMAHA, Neb., is to have a new electric lighting company. Mr. G. Pantaleoni, of the Westinghouse Electric Co., has been recently in that city completing arrangements for putting in the large plant to be furnished by the Westinghouse company.

THE FORT WAYNE JENNEY alternating plant at Harlem, N. Y., was recently tested by a disinterested electrician and was found to be furnishing 13 lights to the horse-power.—*Western Electrician,*

THE BRUSH ELECTRIC LIGHT CO.'s suit against Owen Pixley & Co., of Indianapolis, which involves the entire arc system of electric lighting, was dismissed by Judge Gresham, June 5th, for want of equity. Although Owen Pixley & Co. are the nominal defendants, the real defendants are the Jenney Electric Light Co., of Fort Wayne, who put in the plant in controversy, and all others who use the arc system. Judge Gresham's opinion is as follows :—

"1. The invention is shown in the patents, 212,183 and 219,208, but in 212,183 the examiner held that Brush's claims were too broad. The decision was acquiesced in, and the invention which was there described, claimed and rejected, is now claimed in the patent sued on. The rejected invention was dedicated to the public by acquiescence in the ruling of the examiner, and cannot be claimed in a subsequent patent against others who meantime entered the field and used the rejected invention.

"2. The patent in suit is limited to solenoids and cores mechanically opposed, and it does not include the common or electro-magnet, and thus construed, the patent sued on is not infringed by the defendants."

MR. ELIAS E. RIES, of Baltimore, has contrived a new inductorium or transformer, adapted for regulation within wide limits. The invention is described in U. S. patent No. 380,138, March 27th, 1888, issued to Mr. Ries—to which our readers are referred —our space not permitting fuller notice at this time.

A DESPATCH from Washington states that arrangements have now been pefected by the Lighthouse Board for the illumination of buoys in New York harbor, and that contracts for the work will be made at once. There will be six buoys lighting the channel and furnished with current from the plant at Sandy Hook light station. The plant is to cost altogether about $20,000, and the cost of the maintenance is put at about $3,000 a year. It is believed that when the arrangements have been perfected ships will be able to come through Gedney Channel as easily by night as by day.—*Electrical World.*

Foreign.

Austria.—CENTRAL STATION LIGHTING BY WATER POWER.—A central electric light station is being installed in Trient, Austria, the power to be supplied by a tributary of the Etsch. The waterfall is 2,000 yards from the centre of the town, and 330 feet above it. The water for the turbines is carried by a tunnel 2,000 feet long to an artificial reservoir of 900 tons capacity, and the supply is at the rate of 1,600 gallons per minute. From the reservoir the water is carried by iron tubes of 35 inches diameter to the turbine house, 2,700 feet distant. The lower portions of the supply main have a pressure of 120 pounds per square inch ; they have been tested up to 375 pounds. The sluice valve at the lower end of the supply main is subjected to a total pressure of 164 tons. The total power available varies from 800 h. p. to 400 h. p., according to the season and climatic conditions. The power required for lighting purposes is estimated at 240 h. p., and the town authorities who are carrying out this work propose to utilize an average of 300 h. p. in the day time, and 150 h. p. in the evening for working motors. The tunnel and reservoir have cost 122,000 florins, and the central station is estimated at 98,000 florins, making a total of 220,000 florins. The working expenses, including depreciation and interest, are estimated at 48,000 florins, and to cover this expenditure the light would be supplied at the rate of 3.75 kreuzer, or say about 7d. per 16 c. p. lamp hour ; but when a greater number of lamps are taken up by the subscribers the town will be able to reduce the cost per lamp hour considerably below the figure quoted. The installation is to be in working order in November next.

Italy.—THE ALTERNATING CURRENT SYSTEM WITH UNDERGROUND CONDUCTORS IN ITALY.—Mr. Emilio Mayatti, of Rome, in a letter printed in *Engineering* March 24, states that three central station electric light installations of considerable size are now operating in Italy, using the alternate current and transformer system and underground conductors. The largest of these plants is that of the Anglo-Roman Gas Company, which now lights daily upwards of 5,000 incandescent lamps, and is constantly extending its service.

All the underground conductors for these installations have been manufactured by the house of Siemens and Halske, of Berlin, who have taken special precautions for insuring a trustworthy service. The cables are composed of two highly insulated concentric conductors, protected against external and mechanical injuries by a lead sheath and a double spiral band of iron. Upwards of 40,000 meters of such conductors have been laid in Italy alone.

PERSONAL MENTION.

MR. E. M. BARTON, president of the Western Electric Co. of Chicago and New York, sailed for Europe, June 27th, with his family. Mr. Barton will, it is understood, spend a few months in Continental travel, giving some attention to business meanwhile —returning to Chicago before Winter, after establishing his family in Germany, for a year or so, for special educational facilities.

MESSRS. BALDWIN, DAVIDSON & WIGHT, attorneys-at-law and solicitors of patents, 25 Grant place, Washington, D. C., and 38 Park row, New York, succeeded, April 1 last, to the business of the long established firm of Baldwin, Hopkins & Peyton, of Washington.

Mr Baldwin formed an association with Edward C. Davidson, of the late firm of Baldwin & Davidson, of New York, and Lloyd B. Wight, attorney-at-law, of Washington, who was for many years connected with the old firms.

Baldwin, Davidson & Wight retain the offices, books, papers and employés of both firms, and conduct patent soliciting and litigation in all branches at both places under the firm name of Baldwin, Davidson & Wight.

MR. EDWARD E. HIGGINS, formerly of the Standard Electric Co., St. Johnsbury, Vt., some weeks ago accepted a position with the Sprague Co., as managing agent for Western N. Y., with headquarters at Buffalo. We congratulate the Sprague Co. on the acquisition of Mr. Higgins to their staff. His ability and energy are well approved.

MANUFACTURING AND TRADE NOTES.

THE ELECTRICAL SUPPLY CO. having discontinued their New York office, announce that they have made Messrs. T. F. Hunter & Co. their New York agents. Mr. Hunter's six years' experience with the house is a guarantee that the business will be promptly and carefully attended to. Messrs. T. F. Hunter & Co. announce that they have taken, and now occupy, since May 1, 1888, the store 37 Church street, New York.

MESSRS. SHIELDS AND O'ROURKE, of 98 Fifth avenue, Pittsburgh, Pa., have started in business as contractors and builders of overhead lines for electric street railways. They have already built the lines of the Bentley-Knight road at Allegheny City, and they are now reconstructing the lines of the Daft road at Asbury Park, N. J. Both Mr. Shields and Mr. O'Rourke have had experience of practical work in building telegraph and electric light lines.

THE SPRAGUE ELECTRIC RAILWAY AND MOTOR CO. have received an order from the U. S. government for motors for use in the naval service, and an installation is to be made at once on board the U. S. steel cruiser "Chicago," of motors to be used in the training and elevation of the guns. The electrical and mechanical apparatus required for this work will have to be of the most perfect construction; and the Sprague company may feel honored in having been selected to accomplish the required results.

MESSRS. PARTRICK AND CARTER'S new catalogue of electrical apparatus and supplies is a very comprehensive list. Like other old established electrical houses, they have widened the scope of their business with the constantly increasing number of applications of electricity to useful purposes.

THE HALL ELECTRIC PUMP CO., Plainfield, N. J.—New York office 195 Tribune building—are offering a very compact apparatus consisting of a rotary pump and an electric motor mounted on one base and joined up by a worm gear. A "C & C" motor is shown in the illustration of their circular. The whole gives the impression of an exceedingly useful combination for elevating water in building accessible electric light or power circuits.

MESSRS. P. A. DOWD & CO., No. 239 Broadway, New York city, agents, Sprague Electric Railway & Motor Co., report the following among recent sales of the standard motors for elevators :—Brown & Rittenhouse, 139 Reade street, 10 h. p.; Jno. A. Willet & Co., 137 Reade street, 10 h. p.; Rufus L. Cole, 141 Reade street, 5 h. p.; P. Dauphin, for machinery, 151 Fulton street, ½ h. p.; Lehr & Lock, 37 John street, 1 h. p.; Heller & Birdel, 23 Maiden lane, 1 h. p ; Jno. Robinson & Co., for elevator, 45 Murray

street, 2 h. p.; C. G. Braxmar, 36 Cortlandt street, 1 h. p.; Lazell, Dalley & Co., for elevator and machinery, 110 Beekman street, 7½ h. p.; Kalle & Co., 77 John street, 5 h. p.: Jas. S. Barrow & Co., for elevators, 141 Chambers street, 5 h. p.; Gold & Stock Tel. Co., for transmitters, 16 & 18 Broad street, 5 h. p.; Thurber, Whyland & Co., for printing presses, 143 Chambers street, 3 h. p.; Whitelaw Reid, pumps etc., Ed. *Tribune*, 2 h. p.

THE WATERHOUSE ELECTRIC AND MANUFACTURING Co., of Hartford, Conn., have issued a new catalogue, and show great progress during the past year in their arc lighting system. The dynamo is compact, and of the Gramme type, being series wound; the regulator is a most important part of the system. In regulating, the brushes have a fixed position on the commutator. There are three brushes—two main and one auxiliary brush. The current from the armature is carried in two circuits to the lamp line. The field circuit starts from the armature at the upper main brush and passes around the field magnets of the dynamo and to the point where it joins the local circuit. The local circuit leaves the armature by way of the auxiliary or upward forward brush and joins the current from the field circuit, the sum of the two currents being the amount passing through the lamps. After passing through the lamps the current from both the field and local circuits returns to the armature by way of the lower main brush. When lamps are turned off, instead of an increased current passing around the field magnets, which would be the usual result, the current is automatically reduced and the current in the local circuit is increased in a like proportion; so that on the lamp circuit the current passing through the lamps is the same whether one lamp or the full number are burning. A uniform light can therefore be maintained. As an example, if the field circuit shows six amperes and the local circuit four amperes, the lamp circuit would have the sum of the two or ten amperes. If any number of the lamps are turned off, an instant change occurs in the field circuit, and we will say enough are turned off to reduce it to four amperes. The local circuit would then show an increase to six amperes and no difference would be seen in the lamps because the sum of the two currents equals ten, the same as at first. It is readily seen that the current cannot build up in dynamos so regulated.

The Waterhouse company announce their willingness to show at their factory that the above changes occur in the current on the local and field circuits. All of their central station plants are said to turn off lights at will, without the current building up.

Ansonia, Conn.—Derby Horse Ry. Co.—*Pr.* Jno. B. Wallace; *Sec.* and *Treas.* Wm. J. Clark; *Supt.* Jas. D. Kennedy; 4 mi.; g. 4-8½: 45 lb.; 3 m. c.; 1 m.; sta. —— h. p.: overhead cond. THOMSON-HOUSTON.

Appleton, Wis.—Ap. Electric St. Ry. Co.—*Pr.*, J. E. Harriman; *Sec.*, F. W. Harriman; *Tr.*, F. W. Harriman; *G. M.*, A. A. Jöhnson; *Eng.*, N. M. Edwards; 3.5 mi.; g., 4-8½; 35 lbs.; 5 c.; 5 m. c.; sta., 60 h. p.; water power; overhead cond. VAN DEPOELE.

Asbury Park, N. J.—Seashore Elect. Ry. Co. (41 Wall St., N. Y.) *Pr.*, F. W. Childs; *Sec.*, W. P. Stevenson; *Supt.*, G. L. Jeralomon; 4 mi.; g. 4-8½; 47 lbs.; 12 m. c.; sta. 100 h. p.; overhead cond. DAFT.

Baltimore, Md.—Balt. Union Pass. Ry. Co.—*Pr.*, N. Perrin; *G. M.*, T. C. Robbins; *Sec.*, Leon Fender; 2 mi.; g., 5-4½; 47 lb.; 4 m. c.; sta. —— h. p.; overhead cond. DAFT.

Binghamton, N. Y.—Washington St., Asylum & Park R. R.—*Lessee*, S. M. Nash; *Supt.*, H. P. Wilcox; *Eng.*, E. P. Morris; 4.5 mi.; g. 4; 35 lb., 6 m. c.; sta. 100 h. p.; overhead cond. THOMSON-HOUSTON.

Birmingham, Ct.—Derby Horse Railway Co.—*Pr.*, H. H. Wood; *Sec.*, Wm. J. Clark; *Treas.*, Chas. E. Clarke; 4 mi.; 94′ 8½″; m 5; c. 4; h. p. 100. VAN DEPOELE.

Carbondale, Pa.—Carbondale & Jermyn St. Ry.—*Pr.*, John W. Aitken, *Sec.* and *Treas.*, J. E. Burr; *G. M.*, John Aldrich; 5 mi.; g. 4-8½; 30 and 60 lb.; 3 m. c.; 1 m.; steam power; sta. 75 h. p.; overhead cond. SPRAGUE.

Columbus, O.—Columbus Consolidated Street Ry. Co.—*Pr.*, A. D Rodgers; 2 mi.; g. 5-2; 2 m. c.; 30 lbs.; 2 c.; sta., 250 h. p.; underground conduit. SHORT.

Detroit, Mich.—Detroit Elect. Ry. Co.—*Pr.*, N. M. Campbell; *Sec.*, B. Duffield; 2 mi.; g.——; 30 lb. T; 4 m. c.; sta. —— h. p.: overhead cond. VAN DEPOELE.

Highland Park Ry. Co.—*Pr.*, Frank E. Snow; *Sec.*, Fremont Woodruff; 3.5 mi.; g. 4-8½; 25 and 35 lbs.; 2 c.; 4 m. c.; sta. 60 h. p.; conduit. FISHER.

Easton, Pa.—Lafayette Traction Co.—*Pr.* J. Marshall Young; *Sec.* and *Treas.*, D. W. Nevin; *Supt.*, Mr. Richardson; 1 mi.; g. 5-2; 35 lb.; 2 m. c.; sta. 40 h. p.; overhead cond. DAFT.

Fort Gratiot, Mich.—Gratiot Elect. Ry.—Officials same as Port Huron Elect. Ry.; 1.75 mi.; g. ——; 16 lb. T; 1 c.; 1 m.; sta. —— h. p.; conduit cond. VAN DEPOELE.

Ithaca, N. Y.—Ithaca St. Ry. Co.—*Pr.*, D. W. Burdick; *Sec.*, J. Murray Mitchell; *Tr.* T. F. Van Fleet; 1 mi.; g. 4-8½; 30 lb. T.; 2 m. c.; sta. 20 h. p.; overhead cond. DAFT.

Jamaica, N. Y.—Jam. & Brooklyn R. R. Co.—*Pr.*, Aaron A. Degrauw; *Sec.*, Martin J. Duryea; *Supt.*, Wm. M. Scott; 10 mi.; g. 4-8½; 56 and 60 lb.; 6 m. c.; sta. 100 h. p.; overhead cond. THOMSON-HOUSTON.

Lafayette, Ind.—Lafayette St. Ry.—*Pr.*, G. E. C. Johnson; *Sec.*, T. J. Levering; 2.25 mi.; g. 4-8½; 52 lb.; 8 m. c.; overhead cond. SPRAGUE.

Lima, O.—The Lima St. Ry. Motor & Power Co.—*Pr.*, B. C. Faurot; *Sec.*, F. L. Langan; *Supt.*, J. H. Rose; 4 mi.; g. 4-8½; 40 lb.; T; 6 m. c.; sta. 100 h. p.; overhead cond. THOMSON-HOUSTON.

Los Angeles, Cal.—Los Angeles Elect. Ry. Co.—*Pr.*, G. H. Bonebrake; *Sec.*, and *G. M.*, C. H. Howland; 5 mi.; g. 4-8½; —— lb.; 4 m. c.; sta. ——h. p.; overhead cond. DAFT.

Mansfield, O.—Mansfield Elec. St. Ry. Co.—*Pr.*, Edw. Oathout (New York); *Sec.*, C. E. McBride; *Supt.*, W. G. Root; *Eng.*, Knight Neftel; 4.5 mi.; g. 4-8½; 43 lb.; 5 m. c.; sta. —— h. p.; overhead cond. DAFT.

Meriden, Conn.—New Horse R. R.—*Pr.*, T. J. Lathram; *Sec.* and *Tr.*, T. A. Lamb; 5 mi.; g. 4-8½; 35 lb.; 12 m. c.; overhead cond. DAFT.

Montgomery, Ala.—Capital City Elec. St. Ry. Co.—*Pr.* E. B. Joseph; *Supt.* G. B. Shellhorn; *Sec.*, W. F. Joseph; 7-9 mi.; g. 4; 42 lb.; 14 m. c.; sta. 150 h. p.; overhead cond. THOMSON-HOUSTON.

Port Huron, Mich.—Port Huron Elect. Ry.—*Pr.*, Wm. P. Botsford; *Sec.* and *Supt*, Jas. H. Talbot; 2.75 mi.; g. 4-8½; 27 lb.; 3 m. c.; sta. 55 h. p.; overhead cond. THOMSON-HOUSTON.

Richmond, Va.—The Richmond Union Pass. Ry. Co.—*Pr.*, W. R. Trigg; *Sec.* and *Tr.*, Andred Pizzini; *G. M.*; G. A. Burt; *Eng.* A. L. Johnston; 18 mi.; g. 4-8½: 45 lb.; 40 m. c.; sta. 400 h. p.; overhead cond. SPRAGUE.

San Diego, Cal.—San Diego St. Ry. Co.—*Pr.*, Dr. Granchenor; *V. P.*, Juan Francesco; 9 mi.; 4 m. c.; overhead cond. HENRY.

St. Catherines, Ont.—St. Catherine's, Merritton & Thorold St. Ry. Co.—*Pr.*, E. A. Smyth; *Sec.*, A. P. Friesman; *Supt.*, R. McMaugh; *Eng.*, W. S. Smith; 5.75 mi.; g. 4-8½; 30 lb.; 4c.; 12 m. c.; sta. 400 h. p. (water power); overhead cond. VAN DEPOELE.

St. Joseph, Mo.—Union Ry. Co.—*Pr.*, Seymour Jenkins; *Sec.* and *Tr.*, A. Steinacker; *Supt.*, Chas. Wilson; 9½ mi.; g. 4-8½; 52 lb.; 8 m. c.; overhead cond. SPRAGUE.

Scranton, Pa.—Scr. Suburban Ry. Co.—*Pr.*, Edw. B. Sturges; *Sec.*, G. Sanderson; *Tr.* T. F. Torrey; *Supt.* and *G. M.*, B. T. Killam; *Eng.*, J. Nazel; 4.5 mi.; g. 4-8½; 35, 40 and 52 lb.; 14 m. c.; sta. 300 h. p.; overhead cond. THOMSON-HOUSTON.

Wheeling, W. Va.—Wheeling Ry. Co.—*Pr.*, Jno. Spiedel; *Sec.*, Jno. M. Sweeney; 5.25 mi.; g. 5-2; 45 lb.; 12 m. c.; sta. 240 h. p.; overhead cond. THOMSON-HOUSTON.

Wilkesbarre, Pa.—Wilkesbarre & Suburban St. Ry. Co.—7 mi.; g. 5-2; 50 lb.; 3 m. c.; overhead cond. SPRAGUE.

Wilmington, Del.—Front & Union St. Ry. Co.—*Pr.*, G. W. Bush; *Supt.*, S. A. Price; *Tr.*, E. T. Taylor; g, 5-2; —— lb.; 7 p. c.; operated by mules. SPRAGUE.

Windsor, Ont.—Windsor Elect. St. Ry. Co.—*Pr.*, W. M. Boomer; *Sec.*, A. H. Joseph; *Supt.* W. C. Turner; *G. M.*, P. C. Ponting; 1.5 mi.; g. 3-6; 25 lb.; 1 c.; 1 m. c.; sta. 20 h. p.; overhead cond. VAN DEPOELE.

Woonsocket, R. I.—Woonsocket, St. Ry. Co.—*Pr.*, Horace H. Jenckes; *Sec.* and *Eng.*, Willard Kent; 1 mi.; g. 4-8½; 25 and 50 lb. T; 1 m. c.; sta. 1,000 h. p.; overhead cond. THOMSON-HOUSTON.

Constructing or Under Contract.

Attleboro, Mass.—Att., N. Attleboro & Wrentham St. Ry. Co.—*Pr.*, H. G. Bacon; *Tr.*, J. E. Draper; *G. M.*, H. M. Daggert, Jr.; 6 mi.; g. —— lb.; —— c.; —— m.; sta. —— h. p.; overhead cond.

Brockton, Mass.—East Side St. Ry. Co.—*Pr.*, A. F. Small; *Clerk*, C. A. Noyes; *Tr.*, C. D. Fullerton; *Eng.*, E. L. Brown; 4½ mi.; g. 4-8½; 40 lb.; 4 m. c.; steam-power sta. 60 h. p.; overhead cond. SPRAGUE.

Buffalo, N. Y.—Citizen's Elect. Ry. Co.—*Pr.*, A. P. Wright; *Sec.*, F. F. Fargo.

Chattanooga, Tenn.—Chat. Elect. St. Ry. Co.—*Pr.*, C. A. Lyerly; *Sec.*, C. E. Scott; *Tr.*, C. V. Brown; *G. M.*, E. Scott; 4 mi.; g. 4-8½; 25 lb.

Cincinnati, O.—Mt. Adams and Eden Park Inclined Ry. Co.—*Pr.*, Geo. B. Kerper; *Sec.*, J. R. Murdock; *Tr.* and *G. M.*, G. B. Kerper; *Supt.*, R. Palley; *Eng.*, H. Kolf; 1 mi.; g. 5-2½; 52 lb.; 3 m. c.; 3 m. overhead.

Davenport, Iowa.—3.5 mi.; 8 m. c.; overhead cond. SPRAGUE.

Dayton, O.—White Line St. R. R. Co.—*Pr.* John A. McMahon; *Sec.* Chas. D. Iddings; *Treas.* Michael A. Nipgen; 8.5 mi.; g. 4-8½; 38 lb.; 16 c.; 3 m. c.; sta. 240 h. p.; overhead and conduit cond. THOMSON-HOUSTON.

Elsinore, Cal.—Elsinore Lake Shore Elect Ry. Co.—*Pr.*, D. G Dexter; *Sec.* and *Manager*, H. L. Courad; *Tr.*, F. H. Heald.

Erie, Pa.—Erie City Pass. R. R. Co.—*Pr.*, W. W. Reed; *Sec.*, J. L. Sternberg; *Supt.*, Jacob Borst.

Flushing, N. Y.—Flushing & College Point St. R. R.—*Pr.*, J. Dykes; *Sec.*, Charles Frey; *Tr.*, Henry Clement; g. 4-8½; 45 lb.; 1 mi.; storage bat's.

Harrisburg, Pa.—East Harrisburg Pass. Ry. Co.—4.5 mi.; 6 m. c.; overhead cond. SPRAGUE.

Lakeside, O.—3 mi.; 2 c.; overhead cond.

Lincoln, Neb.—Lincoln Cable Ry. Co.—*Pr.*, J. H. Ames; *Sec.*, L. Coon; 5 mi.; g. 4-8½; 56 lb.; 10 m. c.; storage bats.

Louisville, Ky.—Central Pass. R. R. Co.—*Pr.*, B. du Pont; *Sec.*, J. C. Donigan; —— mi: g. 5.

Meriden, Conn.—Meriden Horse R.R. Co.—*Pr.*, Geo. R. Curtis; *Sec.* and *Tr.*, C. L. Rockwell; *Supt.*, D. Barker; 5 mi.; g. 4-8; 35 lb.; 12 m. c. DAFT.

Newton, Mass.—Newton St. Ry. Co.—*Pr.*, H. B. Parker; *V. P.*, Joseph W, Stover; *Sec.* and *Treas.*, H. C. Pratt (office, Newtonville, Mass); 6 mi.; g. 4-8½; 52 lb.

New York, N. Y.—N. Y. & Harlem (Fourth Avenue) R. R. Co.—*Pr.*, C. Vanderbilt; *Sec.* and *Treas.*, E. V. W. Rossiter; *Supt.*, Alfred Skitt; 18½ mi.; g. 4-8½; 60 and 75 lb.; 10 m. c.; storage bats. JULIEN.

New York, N. Y.—North & East River Ry. Co.—*Pr.*, W. W. Laman; 1 mi.; g. 4-8½; conduit conductor. BENTLEY-KNIGHT.

Omaha, Neb.—Omaha Motor Ry. Co.—*Pr.*, Dr. S. D. Mercer; *Sec.*, J. T. Hertzman; *Treas.*, S. S. Curtis; 5 mi.; g. 4-8½; 56 lb.; 20 m. c.; sta. 250 h. p.; overhead cond. VAN DEPOELE.

Ontario, Cal.—Ontario & San Antonio Heights Ry. Co.—*Pr.*, Chas. Frankish; *Sec.* and *Treas.*, D. McFarland; 8 mi.; g. 4-8½; 34 lb.; 4 c.; 3 m.; overhead cond. DAFT.

Philadelphia, Pa.—Lehigh Ave. Ry. Co.—*Pr.*, J. T. Banting; *Sec.* and *Treas.*, J. McK. Barron; 6 mi.; g. 5-2½; 47 lb.; storage.

Port Chester, N. Y.—P. C. & Rye Beach St. Ry. Co.—*Pr.*, F. H. Skeele; *Sec.*, E. H. Cook; *Tr.*, C. D. Newton; *V. P.*, M. Dillon; *Supt.*, T. M. Burt; 3 mi.; g. 4-8½; 38 lb.; 5 m. c.; overhead DAFT.

Revere, Mass.—Lynn & Boston R. R.—Ocean Ave. line; overhead cond. THOMSON-HOUSTON.

Rochester, N. Y.—Rochester Elect. Ry.—*Pr.*, A. T. Soule; *Sec.*, J. B. Perkins; 9 mi.; 4-8½; 40 lb.; 20 c.; 8 m.

St. Louis, Mo.—Lindell Ry. Co.—*Pr.*, J. H. Lightner; *Supt.*, G. W. Baumhoff; *Eng.*, E. J. Bagnall; —— mi.; g. 4-10; 65 lb.; 1 m. c.; 2 m.; 3 p. c.; storage bats.

Sacramento, Cal.—Sac. Elect. Ry. Co.

Salem, Mass.—Naumkeag St. Ry. Co.—*Pr.*, C. Odell; *Tr.*, H. Wheatland; *Sec.*, J. F. Hickey; *Supt.*, W. B. Furgurson; 1½ mi.; g. 4-8½; 6 m. c.; 35 lb.; 80 p. c.; sta. 100 h. p.; overhead cond. SPRAGUE.

San Jose, Cal.—San Jose Motor Co.—*Pr.*, J. W. Rea.

Sault Ste. Marie, Mich.—S. St. M. St. Ry. Co.—*Pr.*, E. M. Lacy; *Sec.*, F. Ryan; *G. M.*, L. G. Cody; 2 mi. FISHER.

Scranton, Pa.—The Nayaug Crosstown R. R. Co.—*Pr.*, E. B. Sturges; *Sec.*, A. Frothingham; *Tr.*, G. A. Jessup; *Supt.* and *Eng.*, T. Gibbs; 1-5 mi.; 4-8½; 52 lb.; 2 m. c.; steam power; sta. 250 h. p.; overhead cond. VAN DEPOELE.

South St. Paul, Minn.—So. St. Paul Rapid Transit Co.—*Pr.*, A. E. Clark; *Sec.* and *G. M.*, J. H. Lawrence; 8 mi. (Enos elevated railway); 40 and 56 lb.; 10 m. c.; track conductors. DAFT.

Springfield, Mo.—2 mi. FISHER.

Sunbury, Pa.—Sun. & Northumberland St. Ry. Co.—*Pr.*, H. E. Davis; *Sec.*, L. H. Kase; *Tr.*, S. P. Wolverton; 3 mi.; 4 c.; overhead cond.

Syracuse, N. Y.—Third Ward Ry. Co.—*Pr.*, Wm. B. Cogswell; *Sec.* and *Treas.*, W. S. Wales; *G. M.*, H. McGonegal; 4 mi.; g. 4-8½; 8 m. c.; 4 p. c.; steam power; sta. 250 h. p.; overhead cond. THOMSON-HOUSTON.

Worcester, Mass.—Worc. & Shrewsbury—(To be changed from steam to electricity); 2.7 mi.; g. 3; overhead cond. DAFT.

Notes.

THE BROOKLYN, N. Y., common council has granted permission to the Brooklyn City Railroad Co. to run five electric motor cars over the tracks on Third avenue, from Twenty-fifth to Thirty-ninth street.

THE REPORT of the Richmond Union Passenger Railway for the month of May, shows number of miles run, 50,430; passengers carried, 242,282. The total operating expenses, including everything, are given as only 47 per cent. of the receipts.

THE LOCAL THOMSON-HOUSTON ELECTRIC LIGHT CO. has bought the Hoosac Valley Street Railway, running from North Adams, Mass., to Adams. The purchasers paid $75,000. A plant costing $50,000 will be erected to run the road by electricity. There is talk of an electric railway between North Adams and Williamstown.

AT SAN DIEGO, CAL., there are four and a half miles of electric road in operation, half a mile in construction, and 18½ miles projected The San Diego Electric Rapid Transit Street Car Co. has asked for a franchise to construct feeders on Sixth and Arctic streets.

CARBONDALE, PA.—The Carbondale and Jermyn Street Railway Co. are about to add eight electric motor cars to their equipment and to extend their road.

APPLETON, WIS.—The Appleton Electric Street Railway Co. have had two years of perfect success, and say they save 50 per cent. over animal power.

ITHACA, N. Y.—The Ithaca Street Railway Co. are expecting to extend their line several miles at an early date. The system works well.

PITTSBURGH, PA.—The Pittsburgh, Knoxville & St. Clair Street Railway, went into regular operation June 25th, but in consequence of financial trouble experienced before it begun operations, has gone into the hands of a receiver, and the running of the road has been suspended.

RICHMOND, VA.—The Richmond Union Passenger Railway Co. is extending its road two miles to the Exposition grounds.

KANSAS CITY, MO.—We are advised that the Henry system electric railway at Kansas City, after some months suspension of operation has been definitely abandoned. The conductors have been taken down and the line will be operated by steam dummies. Bad engineering and financiering are assigned as causes of the failure.

AMESBURY, MASS.—It is reported that a company is forming to build an electric railway from Amesbury to Salisbury Beach and from Amesbury through Merrimac to Haverhill.

CLEVELAND, OHIO.—The East Cleveland Railroad Co. has applied for an ordinance permitting the use of electric motors on the Euclid avenue line from Willow avenue to the city limits, and also on the Cedar avenue line.

THE SPRAGUE CO. have closed the contract for equipping the Hartford and Weathersfield railway.

SUPERINTENDENT ALDRICH, of the Carbondale electric road, has made a remarkable record with one of his cars, which is now running its 16th consecutive day without change or filing of brushes. Ordinarily the brushes on a railway motor, with other systems, are expected to need changing or replacing at least once a day and many times oftener, and so this "feat" is something out of the usual line of occurrences and shows what the Sprague motor with judicious and careful handling can do.—*Carbondale Leader*, June 12.

WICHITA, KAS.—The Riverside and Suburban Railway Co. is operated at present by animal power.

DENVER, COL.—The Denver Tramway Co. is abandoned, and is being replaced with 12 miles of the Lane system cable railway.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From May 22 to June 12, 1888 (inclusive).

Alarms and Signals:—*District Telegraph Call-Box*, J. B. Gill, 383,220, May 22. *Electric Alarm Clock*, E. J. Colby, 383,439. *Annunciator*, F. E. Fisher, 383,566. *Electrical Needle Annunciator*, W. E. Gill and R. Segerdahl, 383,-725, May 29. *Electric Signaling Box*, W. D. Browne, 383,941. *Boiler-Alarm*, J. J. Ghegan, 383,946. *Electric Annunciator*, C. E. Scribner, 384,088. *Magneto-Electric Liquid-Level Indicator*, J. J. Ghegan, 384,200. *Fire-Bucket Low-Water Alarm*, J. Nolan, 384,212, June 5. *Electrical Annunciator*, H. S. Downerd, 384,430. *Police Electric Signal System*, C. E. Scribner, 384,476, June 12.

Clocks:—*Circuit Closing Device for Electric Clocks*, C. H. Pond, 383,655. *Electric Apparatus for Winding Clocks*, M. Viau, 383.786, May 29. *Electric Pendulum Clock*, A. L. Parcelle, 384,271. *Electric Winding Attachment for Clocks*, A. J. Reams, 384,472, June 12.

Conductors, Insulators, Supports and Systems:—*Anti-Induction Composition for Electric Cables*, D. Brooks, Jr., 383,096. *Support for Electric Wires*, same, 383,097. *Covering for Electric Wires and Cables*, same, 383,-098, May 22. *Insulator for Electric Wires*, F. E. Keyes, 383,734. *Crawler for Electric or Other Conduits*, H. G. Morris, 383,756, May 29. *Insulated Wire*, H. Splitdorf, 383,919, June 5. *Machine for Covering or Insulating Wire*, J. D. Thomas, 384,404, June 12.

Distribution:—*Production, Transmission and Distribution of Electric Currents*, C. E. Fritts, 383,520. *Combined Alternate Current and Storage System of Electrical Distribution*, H. M. Byllesby, 383,620. *Alternate Current and Storage System of Electrical Distribution*, same, 383,621 and 383,-622. *Combined Alternate-Current and Storage System of Electrical Distribution*, same, 383,623. *Circuit Controlling Apparatus for Electric Lighting Circuits*, O. B. Shallenberger, 383,661. *Coupling of Alternate-Electric-Current Generators*, same, 383,662, May 29.

Dynamos and Motors:—*Dynamo-Electric Machine*, J. W. Easton, 383,113. *Automatic Tightening Device for Armatures, of Dynamo-Electric Machines*, same, 383,114. *Dynamo-Electric Machine*. L. N. P. Poland, 383,320, May 22. *Armature for Electric Motors*, F.E. Fisher, 383,564. *Dynamo-Armature*, same, 383,565. *Armature for Dynamos*, same, 383,567. *Armature for Dynamos and Motors*, H. M. Byllesby, 383,617. *Synchronizing Device for Alternate-Current Dynamos*, same, 383,618. *Armature for Dynamos and Motors*, same, 383,619. *Apparatus for Connecting Alternate-Current Dynamos*, P. Lange, 383,648. *Governor for Electric Motors*, R. H. Mather, 383,651. *Bobbin for the Field Magnets of Dynamos*, A. Schmid, 383,657. *Brush-Holder for Electric Generators*, same, 383,658. *Armature for Dynamos*, A. Schmid and H. M. Byllesby, 383,659; O. B. Shallenberger, 383,663. *Armature for Electric Machines*, same, 383,664. *Mounting Armatures of Dynamos*, G. Westinghouse, Jr., 383,679. *Current-Collector for Electric Machines*, W. Stanley, Jr., 383,832, May 29. *Governor for Electro-Magnetic Motors*, C. F. Brush, 383,857. *Dynamo-Electric Machine or Motor*, A. L. Riker, 384,077. *Governor for Electric Motors*, W. Baxter, Jr., 384,117, June 5.

Galvanic Batteries:—*Galvanic-Battery Excitant*, T. P. Whittier, 383,263. *Battery Zinc*, J. Beattie, Jr., 383,271, May 22. *Electric Battery*, E. A. Wildt, 383,548. *Galvanic Battery Fluid*, H. J. Von Metzradt, 383,677. *Galvanic Battery*, H. B. Cox, 383,706, May 29.

Lamps and Appurtenances:—*Manufacture of Incandescent Electric Lamps*, O. A. Moses, 383,140. *Combined Gas and Electric Light Fixture*, S. B. H. Vance, 383,158 and 383,332. *Electric Lamp*, E. C. Ohmart, 383,411, May 22. *Manufacture of Filaments for Electric Incandescent Lamps*, J. W. Packard, 383,484. *Carbon Conductor for Electric Lamps*, H. J. Von Metzradt, 383,602. *Incandescent Lamp*, H. M. Byllesby and P. Lange, 383,616. *Manufacture of Incandescent Electric Lamps*, E. P. Thompson, 383,675. *Evacuating Electric Lamps*, same, 383,676, May 29. *Cut-Out for Incandescent Lamps*, H. Lamp and M. J. Wightman, 383,891, June 5. *Incandescent Lamp Socket*, J. Spink and C. Gauzentes, 384,478, June 12.

Measurement:—*Differential Expansion Device for Galvanometers*, W. H. Bristol and W. E. Geyer, 383,095, May 22. *Galvanometer*, R. E. B. Crompton and G. Kapp, 383,444. *Voltmeter*, P. Lange, 383,649. *Electric Meter*, G. Westinghouse, Jr., 383,678. *Electric Meter*, G. Westinghouse, Jr. and P. Lange, 383,680, May 29.

Medical and Surgical:—*Electro-Therapeutic Battery*, E. J. Murphy and J. Floyd, 383,899, June 5. *Electric Comb*, C. Busch, 384,561, June 12.

Metallurgical:—*Magnetic Separator*, G. Conkling, 383,8'3; M. H. Smith, 383,918. *Electro-Magnetic Separator*, J. B. Hamilton, 384,035, June 5.

Miscellaneous:—*Electrophorus*, J. D. Culp, 383,105. *Electrical Apparatus for Purifying Water*, A. R. Leeds, 383,184. *Combined Doll and Phonograph*, W. W. Jacques, 383,299. *Fusible Coupling for Electric Fire-Alarm Circuits*, G. G. Smith, 383,377. *Rheostat*, F. J. Crouch, 383,345. *Testing Machine*, A. V. Abbott, 383,385, May 22. *Retouching Device*, G. F. Card, 383,436. *Thermo-Electric-Generator*, R. J. Gulcher, 383,464. *Electric Punch Register*, A. C. Palmer, 383,485. *Thermo-Electric Apparatus for Controlling the Temperature of Water in Pipes*, E. A. Newman, 383,536. *Electro-Magnetic Register*, J. F. McLaughlin, 383,583. *Apparatus for Testing Electric Circuits*, A. D. Wheeler, 383,605. *Electric Cigar Lighter*, R. Belfield, 383,611. *Switch for Adjustable Resistances*, P. Lange, 383,647. *Indicator for Electric Circuits*, O. B. Shallenberger, 383,665. *Apparatus for Detecting Ground-Connections in Electric Circuits*, same, 383,666. *Method of Indicating Electric Currents*, same, 383,667. *Electrical Indicator for Alternating Electric Currents*, same, 383,668. *Electrical Indicator*, same, 383,669, 383,670 and 383,671. *Method of Indicating Electric Currents*, same, 383,672. *Gas-Engine*, C. Sintz, 383,775. *Electric Smelling Bottle*, C. T. Brown. *Device for Preventing Incrustation in Steam-Boilers*, W. B. Bull, 383,795, May 29. *Electric Power Controller*, G. S. Neu, 383,901. *Rheostat*, E. W. Rice, Jr., 383,913. *Switch or Cut-Out for Electric Circuits*, J. J. Wood, 383,933. *Lightning Arrester*, P. O. Keilholtz, 384,042. *Rheostat*, W. H. Knight, 384,044. *Electric Shunting Device*, W. Baxter, Jr., 384,116. *Demagnetizer*, J. Greaves, 384,152, June 5. *Metallic Crest-Tile Lightning Rod*, C. B. Nelson, 384,384. *Electric Circuit-Controller*, O. F. Greim, 384,440. *Electric Circuit-Closing Device*, M. W. Grovesteen and F. G. Jahn, 384,570, June 12.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VII. NEW YORK, AUGUST, 1888. No. 80

TRANS-ATLANTIC ELECTRICAL LITIGATION.

TWO important cases have recently been decided in the English law courts, which may perhaps come to have an important influence upon the future of electrical lighting in that country, and which may possibly be not without some ultimate effect upon similar interests upon this side of the Atlantic. The first of these, in respect to priority of the date of judgment, related to the patent of Gaulard & Gibbs for the distribution of electricity by alternating generators and converters. The circumstances attending the institution of this action, which was on a petition for the repeal of the patent, appear to have been somewhat peculiar. It seems that a corporation known as Sir Coutts Lindsay & Co., working an installation having its central station at the Grosvenor Gallery, in London, originally equipped their system with the Gaulard & Gibbs appliances, having the converters arranged in series on the line. This was done under a contract, whereby the patentees were to be paid a stipulated royalty for every electrical horse-power installed. After the plant had been some time in operation it was placed by the company in charge of an electrician named Ferranti, who subsequently reorganized the plant, placing the converters in parallel and substituting, in part at least, new converters of his own design. A dispute, which in time arose concerning the matter of royalties, led to a cancellation of the contract and a refusal on the part of the licensees to pay further royalties. As a result of this, an action for infringement was commenced by the patentees, while at about the same time Ferranti obtained leave to bring a cross-action for the repeal of the patent. This proceeding appears to have given rise to considerable comment, inasmuch as the real plaintiffs in the case were Sir Coutts Lindsay & Co.; but since the payment of licenses under the patent estopped them from denying its validity, the action was ostensibly brought by an employé. The patent act expressly enumerates, among those who are disqualified to bring such an action, the patentee of a subsequent and subordinate patent. This disqualification was however got over by obtaining a special leave from the Attorney-General to bring the action; a circumstance which has caused much comment, and indeed reminds us, in more ways than one, of the initiatory proceedings which occurred in connection with the late Pan-Electric scandal in our own country. However, the case was tried in court and judgment given (which we print in another column) annulling the patent. An analysis of the reasons upon which the decision of the Court is founded shows that the invention was admitted to be a most useful and meritorious one, and that its novelty was not necessarily impeached by any or all the numerous printed publications and paper patents put in by the defense for the purpose of showing it to have been old. The real difficulty was found in the vagueness and insufficiency of the patentees' specification, which failed to distinguish with sufficient clearness between what the patentees had done and that which was public property. We understand that the case is to be appealed, and it would seem as if there were at least an even chance of a decision favorable to the patentees. Whatever may be the ultimate fate of the British patent, it can have no legal bearing upon the status of the American patent for the Gaulard-Gibbs invention.

The opinion of Justice Kay in the Edison lamp case (which will also be found in another part of our present issue), cannot but be regarded as an exceedingly able one, both by reason of the extent and accuracy of the knowledge of the state of the art displayed in it, and of the unerring instinct by which the real issues of the case have been grasped and dealt with. The Edison-Swan Company went into court with a very strong presumption in their favor, arising, of course, from the circumstance that both the patents sued on, Edison's for the incandescent lamp and Sawyer & Man's method of treating filaments by heat in the presence of a hydro-carbon (known in England as the Chesebrough patent), had been twice sustained in an action brought against Woodhouse & Rawson. But the suit just terminated appears to have been defended with far more boldness, vigor and ability than the others, the efforts of the defendants being mainly directed to establish the inaccuracy and insufficiency of the specification, and to the inadmissability of the broad claim in view of the prior knowledge of the art, as evidenced by the work of Swan, Lane-Fox and other early laborers in the field. Beginning with a masterly analysis of the state of the art and of the voluminous testimony presented on both sides, — and it must be confessed, in the main, exceedingly well presented, —the Justice reaches the conclusion that the Edison patent is invalid, first, because he aims at an exclusive monopoly of all incandescent lamps with carbon filaments, a claim which the Justice says, "is far too wide, considering how little Edison had actually invented;" second, because the lamp described in the specification never became or could become a commercially successful one, and third, because the carbon described could not be made without much previous experimentation. There are other objections stated, but

we have enumerated the leading ones. The Justice also remarked, that if the same materials had been before the judges in the earlier case, he believed they would have reached his conclusion.

A careful examination of these cases, has but served to confirm our first impression, that the adverse result in both was due to precisely the same cause viz:—the utter failure of the solicitors who prepared the specifications to comprehend wherein the real invention consisted, and so to differentiate it properly from the prior work of others. Each ignorantly sought to claim the whole art, instead of the particular step in advance which had really been made, and in thus grasping at a shadow the substance has been permitted to fall to the ground.

In the same judgment, the Sawyer-Man or Chesebrough patent, which is controlled in Great Britain, by the Edison-Swan Company, and in the United States by the Consolidated Company, was fortunate enough to have its novelty and validity emphatically reaffirmed. We imagine it will be found somewhat difficult to compete successfully in the production of incandescent lamps without the employment of the hydro-carbon treatment, and hence the position of the Edison-Swan Company would seem to be a sufficiently secure one, notwithstanding the adverse result with the Edison patent. The British law does not permit the sale within the realm of goods made by a patented process, even though the process be worked outside the jurisdiction, and hence the holders of the Chesebrough patent are secured against foreign as well as home competition. It has been asserted, apparently by authority, that whatever result attended litigation in England respecting a patent, "*ergo*, a like result must follow in this country." It is hardly necessary to point out to the intelligent reader that this is a little doubtful, to say the least.

OVERHEAD WIRES IN NEW YORK.

The developments in the work of the Board of Electrical Control, since the appointment of Mr. Schuyler S. Wheeler as electrical expert some six weeks ago, indicate very clearly that the board and other departments of the municipal government are likely to find their hands full enough of work for some time to come, without building any more subways. The systematic inspection of overhead lines initiated by Mr. Wheeler, and still going forward, has already brought to official notice electrical atrocities that surprise even those who are familiar with the disgraceful aspect of electric lines in the crowded portions of the city. It is undoubtedly a fact that from the beginning of line construction in the city there has been absolutely no official supervision or restraint upon the work, carried on by various and sometimes conflicting companies and for a variety of purposes. The result is that inconveniencies and danger, to say nothing of the disfigurement of the city streets, are due much more to the execrable character and want of systematic plan of the existing network of city wires, than to the overhead system *per se*.

There is no doubt, as Mr. Wheeler says, that the wires must ultimately go underground; but much time must elapse before that work can be satisfactorily accomplished, and the obvious and pressing need now is the efficient prosecution of the work, so energetically begun by the experts' department of the Board of Electrical Control, to initiate and maintain something like electrical law and order among existing lines, a very large portion of which must remain in the air for some years to come, and to restrain or suppress the aerial freebooting that has gone on unchecked hitherto.

The following are a few specimens of the greater enormities reported by Mr. Wheeler:—Four lines of poles on one side of a street; pole, corner of Broadway and 25th street, carrying 20 electric light wires, of which 18 are "dead" and terminate at the pole; at the next pole three "dead" wires start; one wire from this pole shows 13 splices in a single stretch; a house in Stone street has twenty-five "dead" wires running from its roof; a heavy cable, two inches in diameter, extends over housetops and poles from No. 63 Broadway to Canal street and is entirely unused; a prominent telegraph company has a line of poles with cross-arms from the neighborhood of the bridge to 42d street with a single wire on them to maintain right of way.

At the end of July notices of about nine hundred violations of the rules of the board had been sent to the various electric companies of the city, of which one-third or more called for the removal of "dead" wires. Thus far little has been done by the companies in removing them. If the wires are not removed by the owners after a week's time a second notice is served, and at the same time the Bureau of Incumbrances of the Department of Public Works is notified. The bureau has thus far done nothing, the Commissioner of Public Works alleging that no appropriation applicable to removing poles and wires exists. The work of weeding out superfluous poles and wires is therefore in abeyance, except in the relatively few cases where the owners carry it out on notice. About fifty-five miles (measured by the ton) of "dead" wire has been removed by the Metropolitan Telegraph Co.

The Brush Electric Light Co. are reported to have followed out systematically all notices of violation of the rules sent to them, and have ordered a mile of eight conductor cable, to be placed in the subways for their arc light circuits. The United States Illuminating Co. seems disposed to resist the discipline of the Board of Electrical Control, and not only contests in the courts the orders of the board to place certain of its circuits in the subways, but is reported to have been very negligent of the notices of faults in their overhead wires.

In view of the intelligent guidance in its work which the board has now secured in the appointment of a competent expert—one who, through his experience in electric lighting, is acquainted with the difficulties of the situation as they present themselves to the lighting companies,—it seems unlikely that unreasonable requirements will be made, either as to the occupation of the subways, or in the more important matter, at this time—the proper regulation of overhead lines.

As our readers are aware, we are very far from believing that the subways thus far constructed or planned will afford a permanent solution of the city wires problem; but the best way to demonstrate their inadequacy is to try them fairly.

"TRYING IT ON THE DOG."

Mr. Harold P. Brown, Electrical Engineer, essayed, on Monday, July 30th, before the Board of Electrical Control and a number of electricians and reporters, to demonstrate his public assertions in respect to the extremely dangerous character of alternating currents, by means of some experiments on dogs; but the Society for the Prevention of Cruelty to Animals intervened, and stopped the proceedings after one good sized dog had perished. This animal indeed received his quietus from an alternating current, stated to be of 330 volts, after having been first subjected to shocks from an assortment of direct currents up to 1,000 volts, which are stated to have reduced his "ohmic" resistance from 15,300 at the start to 2,500 before the alternate current was applied—and which probably reduced his vitality in a corresponding or greater degree.

To say that one Newfoundland has died in vain for the cause of science is sufficient comment on the matter as it stands. Further remarks are left to our poet in another column.

UNDER the somewhat complacent caption "A Homeric Nod," an esteemed contemporary devotes over a column of editorial. in a recent number, to a very diverting apology for an insignificant error in a technical article that appeared in its columns several months ago, and which it refrained from correcting upon discovery immediately after, "in order to learn whether the error would be noted by its readers, serving both as a measure of their acumen and intelligence." Happily, the editor was not disappointed, numerous letters being received, kindly pointing out the inaccuracy as an unwonted and surprising aberration of the Homeric mind. In addition to its classical title, the editorial is furnished forth with quotations from Beecher, Gladstone, Dr. Johnson, and Horace (the latter thoughtfully translated into the vernacular of the untutored reader), and is not half-bad reading for summer weather. But why, O why, did the editor append a vague and general complaint of alleged prevalent uncredited appropriations from the columns of his journal on the part of contemporaries? Has his Homeric head set to nodding again? In view of his cribbing, a few months ago, of a very important document from another journal, printing it as his own, without credit, he will perhaps permit us to direct his attention to a couplet in homely English—to wit—

"Let them in houses made of glass who dwell
Forbear the flinty missile to propel."

WE regret that pressure upon our space prevents our printing the address of Professor Anthony on "Overhead Wires," delivered at the Electric Club, June 28. Electricians are accustomed to the conjunction of accurate knowledge and common sense displayed by Professor Anthony whenever he talks on electrical subjects, which qualities were not wanting on the occasion referred to. After pointing out the relatively small danger to the general public of electric wires, as compared with the ordinary risks of city life on the streets, the speaker said:—

The danger from overhead wires is by far the least of all the reasons for removing them. Linemen would still have to make new connections, and I am not sure that their danger would not be increased rather than diminished by putting the wires underground.

Incidentally, Professor Anthony caustically paid his respects to the gentlemen who, at a recent electrical convention, gravely stated that an escape on an arc light circuit robbed the field magnets of the dynamo and reduced its out-put, "preventing just so much current from passing back around the field magnets," assigning this as one of the difficulties of underground wires. The professor well remarked that it was not to be wondered at that the general public did not understand the problem, when a president of an electric lighting company tried to enlighten it after this fashion.

WE note that Professor Anthony reaches the conclusion expressed by the ELECTRICAL ENGINEER in October, 1-87, that nothing short of a system of tunnels, large enough to permit the passage through them of men and small trucks, will avail to overcome the inherent difficulties of providing satisfactory subways for general electrical distribution in large cities.

THE agreement upon Atlantic cable rates reached by the competing companies would seem to be a satisfactory close of the cable war, in regard both to the public and the cable companies. The 25 cent rate cannot fairly be complained of as unreasonable, and there can be no doubt that the 12 cent rate was unremunerative to the companies. A fair rate is essential to secure good service. The plucky behavior of the Commercial Cable Co. throughout the contest particularly merits public approval, especially their firm stand against an advance in rates to 50 cent r more per word.

EXTENSIVE preparations are making for the meeting of the National Electric Light Association, in New York, August 29, 30 and 31, at the Hotel Brunswick. Dr. Otto A. Moses, chairman of the executive committee, who is taking active charge of arrangements, may be addressed at 17 East 22d street, the house of the Electric Club.

THE continuation of Professor Holman's valuable "Discussion of the Precision of Measurements," is unavoidably deferred till our next issue.

THE electric light companies are not pursuing a sound policy. The loss of property by fire, personal injuries and death, all tend to create a prejudice against electric lighting which should never have been allowed to gain a foothold.—*N. Y. Corr. Industries.*

OBSERVATIONS.

THE watch controversy which for a space did fail, now trebly thundering swells the gale; and how to make watches non-magnetic is again receiving from the advocates of the various methods, a large assortment of widely varying answers. The poet tells us that "the sentinel stars *set their watch in the sky*;" and a reference to July "Observations" disclose the case of a man who buried his watch in a box of earth with the object of correcting the time of the delinquent. Unless he and the newspaper reporter are chargeable with a derived circuit from the main line of veracity, the experiment was successful and the object achieved. Such a method can, however, it is clear, have no extended application. According to an advertisement in a recent number of an electrical weekly journal, another system, nothing, by the way, like the earth cure, has received the support of "the leading *hirologists* of the world;" and what are homœpathic physicians and reporters as compared with "hirologists!"

* * *

INVENTIONS have played an important part in the electrical history of the United States, and instances are not infrequent of inventors having reaped a financial reward. It is true, however, that there is one invention which not in itself electrical, has been associated with about every department of electrical application, which has perhaps been used more than any other, and which yet has never paid its inventor a dollar's profit. This is the "climbers" or "spurs" used by all linemen in climbing poles, and was invented by Mr. Charles T. Smith.

This thought was suggested to the observer, as he turned over some old correspondence and came across the name of Mr. Smith, in a letter written to him by the late Henry O'Reilly. The following passage occurs in the letter: "I must specially mention your climbing spurs, marks of which are shown on telegraph poles all over the land; by which "spurs" the hardy telegraph builders and repairers can readily ascend the posts to arrange and repair the wires and insulators, freed from the annoyance of ladders and other contrivances, commonly used before you invented this valuable aid for builders and repairers of telegraph lines. Your climbing spurs have, besides greatly promoting the convenience of all concerned, saved annually hundreds of thousands of dollars to the telegraph companies throughout the land." Probably no reader of these Observations will feel inclined to gainsay Mr. O'Reilly's opinion; on the contrary, it is certain that any one who has worn the climbers long enough to "win his spurs," will be disposed to endorse it fully. Suppose they were for the first time produced now; it is safe to say there would be at least 10 applicants for a patent, a four year's interference, and 40 prior inventors.

* * *

MENTION has been made in previous Observations of wondrous inventions in electro-therapeutics. Hat batteries, electro-medical spectacles, and other appliances, have helped to fill the records of the Patent Office, and perhaps also the pockets of the patentees.

"This last quarter of the 19th century," as the pulpit orators call the current period, has been prolific in electrical devices of all kinds, including those of a medical nature. But the creative minds of the earlier ages of the world were not content to ignore entirely the manifestations of the force which was—and is and in all likelihood, ever shall be—unknown, and they accordingly tried to make use of it in the cure of diseases.

All the Year Round, of a comparatively late issue, reproduces some of the wonderful recipes of Pliny the Elder, who was also quite possibly a Benjamin Franklin the Elder. It cannot be proved that he enticed the lightning from the skies, but he told how to make good use of it after its descent. Listen, all ye who suffer with toothache. "If one bite off a piece of some tree that hath been blasted with lightning, provided always that he hold his hands behind him in so doing, the said piece of wood will take away the toothache." Caius Plinius Secundus was somewhat of a philosopher, but he evidently did not believe in enduring the toothache patiently.

ARTICLES.

SPRAGUE MOTOR CURVES.

BY FRANK P. COX, B. S.

THE method used in obtaining these curves is known as Hopkinson's method, and was fully described in *The Electrical Engineer* January and February, 1887. As that article may be somewhat too abstrusely mathematical for many practical electricians, and as this paper is intended to be a reliable guide to such electricians in their work, all the operations will be fully described.

Excepting the dimensions of the machine, only one measurement is necessary. That is to determine the value of the constant ν. This value is the ratio of the total lines of force through the field magnets to the useful lines through the armature. I have described in the last number of this journal the method of finding an expression for these lines. In this case $\nu = 1.76$.

It is also necessary to have a curve representing the relation between the magnetizing force H and the permeability, μ for wrought iron and a similar curve for cast iron.

Hopkinson gives curves for cast and for wrought iron, showing the relation between B, the magnetization and H. From those curves several values of μ have been worked out and the following curves constructed:—

Cast iron. μ	H	Wrought iron. μ
400	10	1130
270	20	700
207	30	495
168	40	384
140	50	315
121	60	268
108	70	233
98	80	208
90	90	188
84	100	170
71	125	135
61	150	117
51	200	92

The method of using this curve will be described later. We must now make use of Hopkinson's formula to find the required magnetizing forces.

The formula is

$$4\pi n c = l_1 f\left(\frac{I}{A_1}\right) + 2l\frac{I}{A} + l f\left(\frac{\nu I}{A}\right) + 2l f\left(\frac{I}{A}\right)$$

Where

"n" is the number of turns on the field,

"c" the current in C. G. S. units,

"I" represents the induction and is the quantity we wish to find the value of.

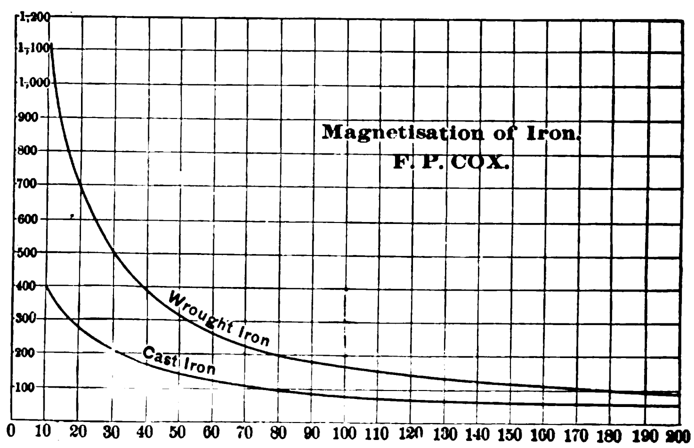
"l_1" is the length of the lines of force in the armature, and is slightly greater than the shortest distance between the pole-pieces. It is in this case 10. c.m.

"A_1" is the cross-section of the iron in the armature, and is .9 of the total cross-section in a horizontal plane; 10% being allowed for lamination. A_1 is 224 sq. cm.

"l" is the perpendicular distance between the faces of pole-pieces and the armature core. l is .7 cm.

"A_2." This is the area of the face of pole-piece, + 13%, to allow for dissipation of field. It is 286 sq. cm.

"l_2" is the length of lines of force in the field, that is, the length of the field core. It is 16.8 cm.



"A_3" is the area of the field cores, and since there are two magnetic circuits in parallel, twice the area of one magnet limb will have to be used. A_3 is 153.4 sq. cm.

"l_3" is the length of lines of force in pole-piece. This cannot be measured *exactly*, but it is approximately 21 cm.

"A_4." As in case of A_3, the mean area of cross-section will have to be doubled, giving 198 sq. cm.

"ν." As stated before, ν is 1.76.

The formula now becomes

$$4\pi n c = 10 f\left(\frac{I}{224}\right) + 1.4\frac{I}{286} + 16.8 f\left(\frac{1.76 I}{153.4}\right) + 42 f\left(\frac{I}{198}\right).$$

It is now necessary to substitute for the functions their values, and to divide the equation up into its parts. The first term represents the force required for the armature, the second that for the air space, the third for the field, and the fourth for the pole-pieces. In the equation the functions may be expressed by multiplying the term by $\frac{1}{\mu}$. Now, to obtain the curve for the armature we vary the magnetizing force $x = \frac{10\,I}{224\,\mu}$ and for the different assumed values of x work out the value of I. The curve is then plotted with these values of x and I. In a similar manner the curves for the other parts are constructed. The air space will in every case be a straight line. Before discussing the characteristic curve it may be well to construct the other curves, as the characteristic is taken directly from them.

We have for the armature

$$x = \frac{10\,I}{224\,\mu} \text{ or } I = \frac{224}{10}\mu x$$

For the air space,

$$x = \frac{1.4\,I}{286} \text{ or } I = \frac{286}{1.4}x$$

For the field,

$$x = \frac{29.6\ I}{153.4\ \mu} \text{ or } I = \frac{153.4}{29.6}\ \mu x$$

For the pole-pieces,

$$x = \frac{42\ I}{198\ \mu} \text{ or } I = \frac{198}{42}\ \mu x$$

Now, when we give to x different values, the value of I for each one is easily worked out, since μ depends directly upon x, and its value can be obtained as follows:—Since x represents the total magnetizing force, we must divide by the length of the line of force to obtain the magnetizing force per unit length. Now having obtained this value we look upon the magnetization curve, which is plotted in terms of μ and magnetizing forces per unit length. This curve gives us the value of μ for this value of x, and having this the value of I follows directly. The following tables give values required in the construction of the curves:—

ARMATURE.

$\frac{x}{l_1}$	x	μ	I
5	50	1550	1,786,000
10	100	1130	2,581,200
30	300	495	3,326,400
50	500	315	3,528,000
80	800	208	3,727,360
100	1000	170	3,808,000

AIR SPACES.

x	I
1000	204300
2000	408600
3000	612900
4000	817200

FIELD.

$\frac{x}{l_3}$	x	μ	I
5.95	100	1410	730,380
17.85	300	765	1,188,810
29.75	500	497	1,287,230
47. 6	800	328	1,359,232
59. 5	1000	270	1,398,600
89.25	1500	189	1,468,530
119.	2000	143	1,481,480

POLE-PIECES.

$\frac{x}{2\,l_5}$	x	μ	I
7.14	300	442	624,546
11.9	500	370	871,350
19.04	800	280	1,055,040
23.8	1000	242	1,139,820
47.6	2000	146	1,375,320
71.4	3000	104	1,469,520

CONSTRUCTION OF CHARACTERISTIC.

From any point on the air space line lay off an abscissa equal to the sum of the abscissas of points in the curves for armature, field and pole-piece, whose ordinates are equal to the ordinate of the selected point in the air space line. This point will be a point in the characteristic curve. Any number of such points can be similarly obtained and the curve drawn through them. This construction does not take into account the effect of the current in the armature, as in this particular machine its effect is practically zero.

We have now all the data required to construct any size dynamo or motor of this type. Suppose, for instance, we wish to build a dynamo of this type with a given number of armature coils to give a certain potential at a given speed of rotation.

On the characteristic take "A" before the curve becomes too nearly horizontal. The induction for this point is 1,150,000, and the magnetizing force 7000 C. G. S. units. The potential this dynamo would develop at the given speed is given by the formula.

$$E = \frac{n\,r\,I}{100\,000\,000}$$

where

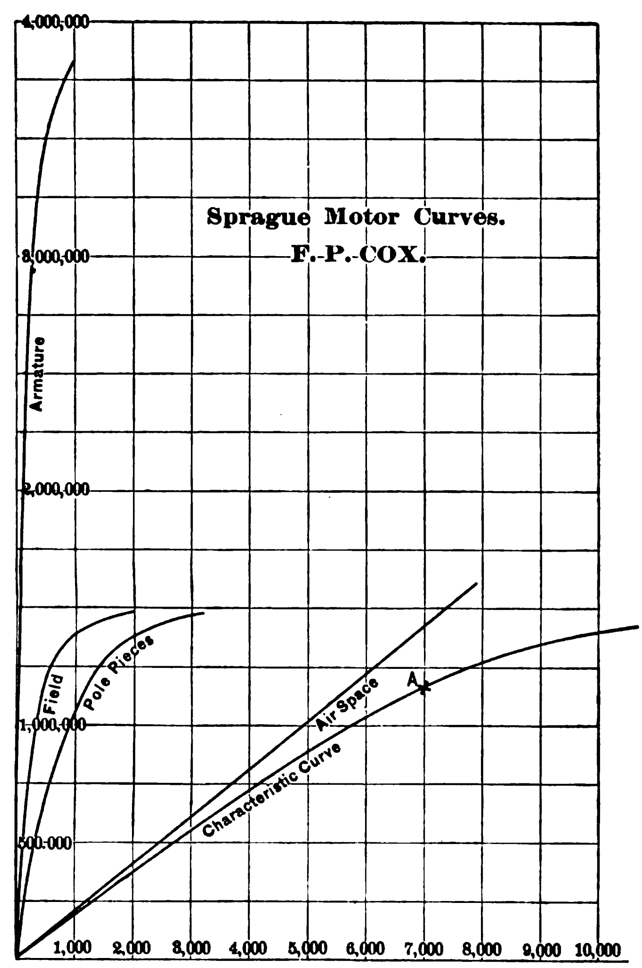
E = volts developed

n = number of armature coils.

r = revolutions per second.

I = induction.

Now this value is perhaps too small, and a larger machine will be required. Silvanus Thompson tells us that "if the linear dimensions of a dynamo be increased n times its output is increased n^3 times." This rule is only approximately true; so that when we select n so that $n^3 E$ = the required potential and construct a new set of curves, we shall find that they are not exactly right.



From this new characteristic we calculate the volts which would be developed at the stated speed, and find that it is either a little too great or small. Some small changes will have to be made in the different parts, until, by successive approximation the required potential is obtained. It is now necessary to know how strong to make the field. The magnetizing force required to produce this induction is expressed by

$$H = 4\,\pi\,n\,c,$$

or

$$n\,c = \frac{H}{4\,\pi};$$

but this is expressed in C. G. S. units, and will have to be multiplied by 10 to be expressed in units in daily use, giving the required ampere turns $= \frac{5\,H}{2\,\pi}$. A few words

upon size of wire to use may not be out of place. We know the potential at the terminals and can approximate to the external resistance, and, therefore, as to the current which will flow through the armature, and thus calculate the size wire required from the following rule. Wires to 2 mm. diameter can safely carry five to six amperes per sq. mm., and wires of 5 mm. diameter can safely carry three amperes per sq. mm. For the field, if it is a shunt machine, its resistance should be at least 364 times that of the armature, so that we can choose any resistance greater than this, only remembering that it must be the resistance of wire of proper size to carry the current, and of such length as to give the correct number of turns.

PHYSICS IN PUBLIC SCHOOLS.

BY C. J. H. WOODBURY.

THAT our public school system should perform all that is required of it demands that the instruction, at least in the more densely populated portions of the country, should extend beyond the mere rudiments of letters and figures, and be broad enough to include a training in accurate observation and correct reasoning. It should include a knowledge of the elements of business and of science in their applications to every-day life; and in this connection it is necessary that the principles of electricity should be accurately taught in our public schools.

By the luck of nomination and the accident of election, I have been a member of a school board for several years, and not long ago there was occasion to examine candidates for teachers' positions. There was an English high school to be started, and at least one prospective vacancy in the classical high school to be filled, and a number in the grammar schools, all of which were positions where the teacher should have some knowledge of modern science as a matter of general intelligence for guiding the miscellaneous reading, or directing the attention or answering the questions of scholars upon technical subjects, even if they were not included strictly in the course of studies.

These teachers' examinations are in writing, and one course of questions included a few interrogations upon topics of physics and chemistry. The only one concerning electricity was, "Explain the principle of the Bell Telephone."

The question was put in this manner, not merely as an examination upon the principles sought for in the question, but because on account of the extended use of the instrument, the large amount of space devoted to it in the newspapers, and the controversies upon its invention; the answers would certainly furnish an indication of the habits of observation and of general newspaper reading on the part of the candidates.

Persons frequently gather a collection of peculiar answers given to questions by school children, as examples of incongruous thought; but these candidates for teachers were, with two exceptions, graduates from high schools of excellent repute, and the majority of them had received instruction in the normal schools. Of the two who were not graduates of high schools each had passed through one of two leading academies in New England. Therefore the answers did not represent the immature thoughts of school children, heedlessly catching on to a few words without realizing their significance, but were the answers of a number of young ladies who had received the benefits of the best public school instruction given in the oldest of our New England states.

The answers of those who attempted any reply to the question were as follows:—

1. The telephone is upon that principle that sound may be transmitted a great distance along a wire.

2. Sound having a medium to carry it will travel.

3. It is carried on by that mighty power, electricity. We ring an electric bell. When we speak we hold a cup or handle to our mouth in order that the sound may be concentrated and pass with more force along the wire. The person who is listening holds it to his ear in order that the sound may be more concentrated and pass with more force to his ears. The principle is electricity being able to transmit sounds a very great distance by connection of wire.

4. The principle of the Bell telephone is based first upon electricity.

5. The principle of the Bell telephone is the application of electricity, by means of a battery, to the conveyance of sound by waves caused by the expansion and contraction of air. Before that was invented, something that corresponded to it, for very short distances, was used. It consisted of a tube with a mouthpiece at both ends, across which were stretched membranes. The one at the side where the speaking is, vibrates; the vibrations are continued through the tube to the other membrane, and to the listener there as sounds. This could be used only for short distances because the vibrations are weak, and for long distances electricity was applied to make them stronger, and iron plates were used instead of membranes.

6. The telephone consists principally of a thin steel plate which is vibrated by a permanent magnet placed just back of it. The voice causes waves of condensation and rarefaction to undulate through the wires, and touching the magnet, causes the thin plate to vibrate with waves of the same kind. Thus the waves being of the same kind as those of the other end of the wires, the sound is reproduced, and one listening, can plainly hear what is spoken at the other end of the apparatus.

7. The voice, striking against the electro-magnet of the speaking tube, sets the magnet into vibration. These vibrations are transmitted along the wire of the tube, and there to the tube at the other end of the connection. The sound waves here strike upon the membrane of the tube and thus reach the ear.

8. The Bell telephone has a small disc which is over a permanent magnet. This disc is kept in place by a cup-shaped cover to which the mouth is applied in sending a message. There are two posts connected with the permanent magnet; one goes into the ground, and the other is all connected with the receiver at the distant station.

9. By means of a telephone, communication can be carried on by articulation. The Bell telephone consists of a small wooden arrangement. This is attached to a wall, and from this wires are extended to the place of communication. There is an opening for the mouth and also a small piece connected to the instrument by a cord to hold it to the ear.

The sounds are transmitted in waves along the wire, and coming in contact with the air strike against the ear drum, and are transmitted through the chain of bones to the openings on the inside, and thence by the optic nerves to the brain.

10. The Bell telephone consists of an instrument which is held to the mouth to speak through. It contains a platinum disc which is set in vibration by the sound waves produced by the voice. It vibrates against a magnet to which are connected two magnets which wind around two screw-cups and then pass through the instrument to the distant station. Over the platinum disc is placed a cup to which the mouth is applied.

It will be noted that none of the answers referred to the transmitter or to any of the accessories of the telephone, that none of them use the widely known expression that its purpose is "for the electrical transmission of speech." In short, they were, collectively, a vague, inaccurate, and unsatisfactory attempt at jumbling words together to express an indefinite idea; and all of them disregarded the request to explain the *principle* of the telephone, and substituted sorry efforts, with all the vagueness of ignorance, to recall disjointed phraseology from the text books.

Another question asked for a definition of five of the following words,—element, specific gravity, force, inertia, unit of heat, unit of work, centre of gravity. The limitations of error very naturally prevented the answers to these interrogatories from being worse than those about the telephone. Force was defined as follows :—

1. Force is a push and a pull.
2. Force is the attraction which one body has for another.
3. Force is anything which changes or tends to change the nature of a substance.
4. Force is anything which occasions a change in a substance.
5. Force is a power by which matter is governed.
6. Force is the propelling movement a body possesses.
7. Force is the propelling movement a body possesses.
8. Force is anything which causes a change in a substance.
9. Force is that which acts upon an object to produce a certain result.

Inertia was defined as,—

1. That phenomena by which a displaced body tends to return to its former position.
2. That power which keeps a moving substance moving and a stationary substance stationary.
3. That which tends to make a body keep its position or remain in a state of rest.
4. Inertia is that when a body is at rest it will remain at rest, when a body is in motion it will continue in motion.
5. Signifies a body at rest.
6. The obstruction which stops a moving body.
7. Inertia is the rate of motion.
8. Inertia is one of the universal properties of matter which a body possesses unless acted upon by some repelling force.
9. Inertia is the state of rest of a body.
10. Inertia is the quality of passiveness.
11. Inertia is that force by which a body may be moved from one place to another.

Unit of heat was defined thus :

1. Heat required to raise the mercury in a glass tube to the zero point.
2. Amount of heat required to heat a certain body.
3. Average time in which a body becomes heated.
4. The standard from which all heat and forces of heat are computed.
5. The regulation made by which to reckon a decrease or an increase.

The questions were framed after a perusal of the text books of physics used by a majority of these applicants ; and the questions were confined to subjects accurately and clearly treated in several of these books, and it could not be truly alleged that the questions led into subjects foreign to the instruction given in the high and the normal schools.

Where shall the responsibility be laid for this sort of thing? Certainly not upon the candidates, who were manifestly unusually bright scholars on other topics ; nor is there any reason to impugn the intelligence of their teachers. Both teachers and pupils were from a too extended range of territory and under a too wide a diversity of environment to admit that the results could be ascribed to any influences purely local in character ; and the results must have been the fault of methods of instruction.

The public school system is so great, reaching to almost every household, and forming a portion of almost every life, that any criticism of its policy nearly approaches to the "impossible indictment of a nation."

It is frequently remarked by high school teachers that girls are slow in physics and good in chemistry, in comparison with boys. The reason, I believe, to be primarily due to the lack of laboratory practice and demonstration, which is a part of the natural experience of the boys in the use of the jack-knife and in familiarity with all sorts of mechanical processes,—an experience often obtained at the expense of a reputation for meddlesomeness ; while the tastes and opportunities of the girls do not offer such chances for learning how to think with their fingers. And yet we do not see that difference in the results of instruction in chemistry, because excellence in that study is the result of memory rather than that of other faculties. It is evident that efficient instruction in physics can only be carried on in connection with laboratories, and that laboratory practice which proceeds concurrent with the studies in the books.

SOME ELECTRIC PROPERTIES AND USES OF CARBON.

BY L. A. BEST.

(Brooklyn Central Grammar School.)

CARBON has become a necessary material in nearly all electrical appliances, and a study of this substance well repays the electrician. He should at least be familiar with its action under different conditions, as changes of temperature, etc. Early last fall I began a series of observations on carbon which was continued until March of this year ; and, while some old results were verified, some others were arrived at that are interesting and useful.

The experiments were divided into four classes:

1st. Methods of determining and the determination of the co-efficient of resistance of carbon due to change of temperature.

2d. The application of the fact that the law of change in carbon is the opposite to that of metals in the construction of a compensated standard ohm.

3d. The investigation of the question, "Does change of pressure effect the resistance of carbon ?"

4th. The effect of change of contacts on the resistance of carbon.

THE LAW OF RESISTANCE.

For the first series several pieces of apparatus were devised, the best of which will be described:

Figure 1 represents the elevation of one form of apparatus as used. A Carré pencil of carbon, K (figure 2), was electro-copper-plated at the ends, A A, and these plated ends were soldered to copper bands, C C, which were fastened (as indicated in figures 2 and 3) to a piece of plate glass, G. Leaders of copper were soldered to these bands, and the whole, with a thermometer, was inclosed in a test tube, T T (figure 1), the bulb of the thermometer being as near the middle of the carbon as possible. The test tube was corked tightly, the leaders and thermometer passing through the cork, the tight corking preventing currents of air. This apparatus was placed in a vessel as indicated in figure 1. W represents a block of wood in which the test tube rests, and B B are braces to hold the tube in place. The leaders L L were connected with an Elliott Bros. dial bridge, and readings were taken for temperatures ranging from 0° C to 100° C. The apparatus being first packed in ice and afterwards heated gradually to the boiling point. Figure 3 represents a method of mounting adopted to prevent any possible effects caused by the carbon being rigidly mounted, as in figures 1 and 2. A copper cup, A′, soldered to the lower band C, was filled with mercury, and the lower end of the carbon dipping in this furnished amalgamated connections and allowed the carbon perfect freedom for expansion and contraction. *The two methods of mounting gave precisely the same results.* The resistance of the apparatus and leaders was determined by connecting the copper bands C C with a heavy copper rod.

Figure 4 represents another form of apparatus used for investigating the effects of high temperatures. The carbon K was plated as before, and fine copper wires were laid lengthwise along the plated parts and bound fast ; these ends were again plated with the wires, and unvarying connections were thus obtained. The carbon was wound with

asbestos paper, and a piece of pure platinum wire was wound around the outside, copper terminals *m m* being fused to the platinum. This apparatus was placed in a ings were taken as high as 1000° C. The platinum was used as a pyrometer, and the magnesium carbonate was used to prevent oxidation of the carbon by the intense

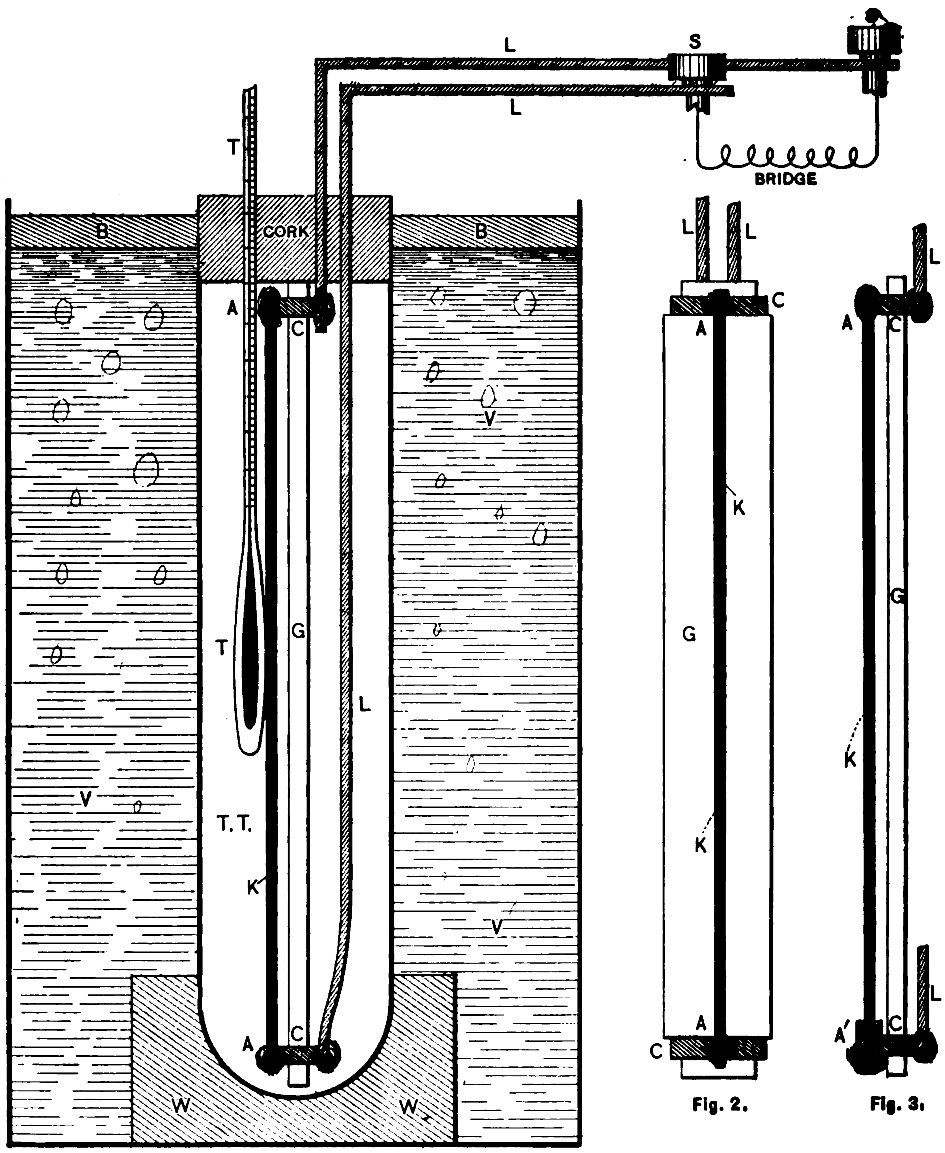


Fig. 2. Fig. 3.

Fig. 1.

Apparatus to Determine Coefficient of Resistance of Carbon.

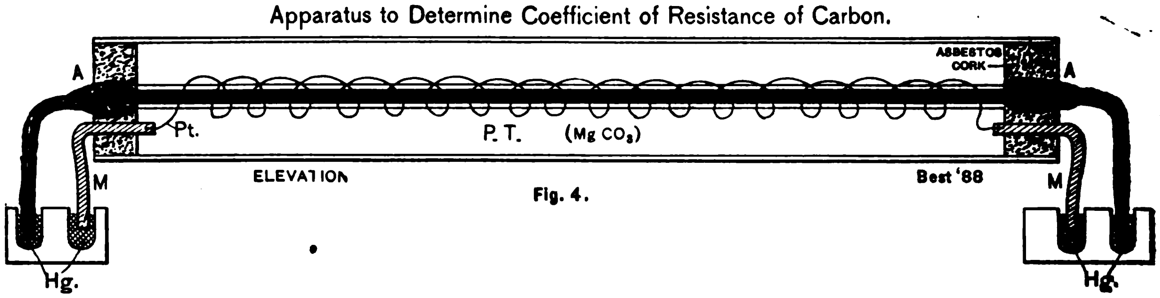

Fig. 4.

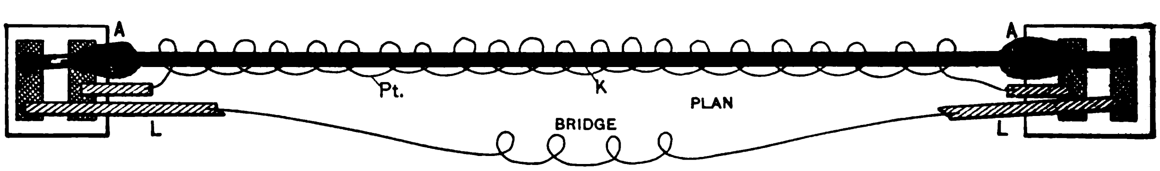

Fig. 5.

porcelain tube filled with magnesium carbonate and corked with asbestos. The tube was placed on a gas furnace, the terminals all furnishing unvarying connections, and read- heat, the $Mg\,C\,O_3$ separating (before reaching the oxidizing point of carbon) into $Mg\ O$ (a non-conductor) and $C\,O$, the latter making an atmosphere in which combustion is im-

possible. From the law of change in platinum the law for carbon may easily be determined. The platinum being wound around the carbon would be of the same temperature, care being taken to keep the apparatus at the temperature required until no change occurred in either the platinum or carbon. Figure 5 gives the plan of the apparatus. Readings were in all cases taken with direct and reversed currents in order to correct for thermo-currents. For low temperatures (0° to 200°) I used a modification of this apparatus with the best results. A thermometer was substituted for the platinum; the carbon was placed in a small glass tube, and the whole placed in a porcelain tube filled with fine sand. Temperatures were easily regulated with this apparatus.

A large number of Carré pencils were experimented upon, and it was found that no two had the same law, the rate of decrease in resistance from 0° C to 100° C varying from 2% to 4%, the mean being very near 3%. I give below the results obtained with one pencil, observations being taken for both increasing and decreasing temperatures to correct any errors resulting from slowness of action of the pencil in reaching a certain temperature.

TABLE I.

Table showing variation of resistance of carbon with change of temperature.

Rising temperatures. Temperature.	Resistance.	Falling temperatures. Temperature.	Resistance.
°		°	
14.8 C	1.8572 ohms	96.6 C	1.8213 ohms.
24.8	1.8532 "	86.4	1.8258 "
35.4	1.8485 "	76.4	1.8301 "
45.1	1.8440 "	65.2	1.8350 "
55.2	1.8394 "	56.2	1.8388 "
64.7	1.8353 "	45.6	1.8439 "
75.8	1.8306 "	36.0	1.8480 "
86.2	1.8260 "	25.3	1.8524 "
96.6	1.8213 "	15.5	1.8570 "

In plotting this series of observations it is easily seen that for low temperatures the law of decrease is constant. The above results give a decrease of 2.38% per 100° Centigrade. Other pencils gave .025, .0255, .035, .04, .03, decrease per 100°. This variation is probably due to different densities of carbons, impurities, etc., etc.

Several carbons were carried through the second apparatus for high temperatures, but on experimenting with the platinum used, I found that it did not follow the law as determined by Matthiessen. I found that each piece of platinum used would have to have its law determined independently. Until the law of my pyrometer is determined I cannot make use of my results.

THE COMPENSATED STANDARD OHM.

Making use of the peculiar property of carbon, *i. e.*, the property of decreasing in resistance with increase of temperature, I constructed a standard of resistance by compensation with copper in parallel circuit, the increase of resistance in copper due to increase of temperature just balancing the decrease of resistance in the carbon due to the same cause, thus giving a constant resistance for varying temperature.

Any one who has tried to make corrections for temperature in a bridge or other apparatus knows how difficult it is to keep a B. A. standard, as at present constructed, at the temperature which gives its correct reading; and he can appreciate the utility of a standard, whether it measure an exact ohm or not, which is *perfectly* constant for all temperatures.

This simple contrivance can be used not alone for slight variations that occur in the temperature of a laboratory during a series of observations, but for variations covering a range of 150° Centigrade, with perfect success, and it is vastly superior to the expensive and *variable* standards now in use.

If a standard ohm is to be constructed, the formula giving the proportions of carbon and compensating metal is deduced as follows:

Let μ be the coefficient of carbon, and ν that of the compensating metal; let r be the necessary resistance of the carbon at 0°, r^1 that of the metal; then from a law of parallel circuits,

$$\frac{1}{r_0} + \frac{1}{r_0^1} = 1 \qquad (1)$$

$$\frac{1}{(1-\mu)\,r_0} + \frac{1}{(1+\nu)\,r'_0} = 1 \qquad (2)$$

from (1)

$$\frac{1}{(1+\nu)\,r_0} + \frac{1}{(1+\nu)\,r'_0} = \frac{1}{1+\nu} \qquad (3)$$

from (3) and (2)

$$\frac{1}{(1-\mu)\,r_0} - \frac{1}{(1+\nu)\,r_0} = 1 - \frac{1}{1+\nu} \qquad (4)$$

or

$$\nu + \mu = \nu\,(1-\mu)\,r_0$$

from which

$$r_0 = \frac{\nu+\mu}{\nu(1-\mu)}$$

If a standard of n ohms were wanted the necessary resistance of the carbon at 0° C would be

$$\frac{n\,(\nu+\mu)}{\nu\,(1-\mu)}.$$

Although the law for resistance of metals is

$$R_t = R_0\,(1 + \alpha\,t + \beta\,t^2)$$

and for carbon

$$R_t^1 = R'_0\,(1 - \alpha'\,t \pm \beta^1\,t^2),$$

I have considered only the coefficients α and α', as practically the others may be omitted for temperatures below 200°, the variation of both carbon and metals for that range being virtually constant.

As an illustration of the above, a pencil whose coefficient was found to be .03 was compensated with copper whose coefficient was assumed to be .388 — *i. e.*, $\mu = .03$, $\nu = .388$. Applying the formula, the amount of resistance that the carbon at 0° must offer is

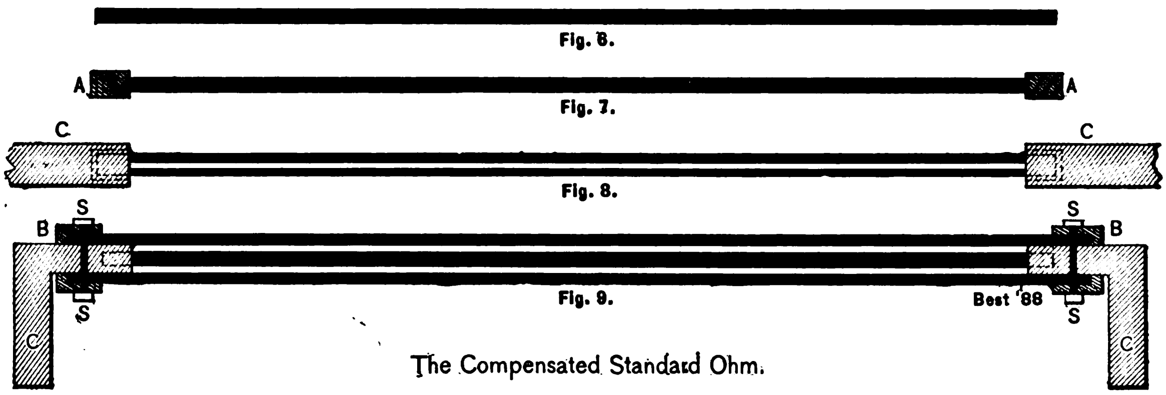
$$r_0 = \frac{.388 + .03}{.388\,(1 - .03)} = 1.11 \text{ ohm.}$$

And since the carbon was measured at 15° C, allowance at the rate of .03 decrease for 100° was made, which gave $r_{15} = 1.1056$ ohms. If a standard of 10 ohms were wanted 11.056 ohms would be cut off instead, which would be plated to give a resistance of 10 ohms.

In preparing a standard ohm, I first determined its law of resistance, using a pencil of several ohms resistance to determine the coefficient; then the formula for copper and the carbon was applied, the necessary length of carbon to give the required standard being computed. A piece about 8 mm. longer than the computed length was cut off and plated at the ends until the intervening strip offered the required resistance (figures 6 and 7); with a little care this can be very accurately done, when all that is necessary to complete the pencil is to plate it until it offers a resistance of just one ohm. This was done by varnishing the rod, leaving a strip about-one half mm. wide from one plated end to the other free from varnish, and then immersing the pencil in the bath and plating until the required resistance was reached. If too much copper were added, it could be removed by careful scraping or by suspending the pencil on the other pole of the cell. A few trials will give a perfect ohm. After compensating, the plated ends were soldered into the ends of copper rods, c c (figure 8), and the pencil was given a heavy coat of varnish. If the pen-

oil were to be preserved it could be mounted as indicated in figure 9. The rod, as shown in figure 8, is inserted in a hard rubber tube whose inner bore is the same as the copper terminals, the tube being two cm. longer than the carbon; brass caps, B B, are then fitted over the ends of the tube, the copper leaders projecting through the caps; the caps, tube and terminals are drilled through at S S, and secured by a strong rivet at each end; the terminals are then bent as indicated in the figure, and we have a perfect available standard. All air may be excluded by gluing the caps on and by soldering the ends where the terminals project through the caps.

One ohm mounted hastily did not vary .003 in 150° C, while a B. A. standard varied as much in 5°. Another run through about 100° C slowly, did not show any variation whatever. I found that on account of copper accommodating itself to any temperature more readily than carbon, being a better conductor of heat, that *sudden* variations of temperature caused temporary variations in the standard; but this disappeared as soon as the carbon reached the same temperature as the copper. But for practical use in the laboratory, with slowly changing temperatures, the apparatus is perfect in its action, and there is no doubt that it can be of great service to many who wish to make accurate measurements.



The Compensated Standard Ohm.

PRESSURE AND CONTACTS.

For investigating the change in resistance offered by carbon under varying pressure, I devised two pieces of apparatus, and obtained exactly similar results from both; the observations proving conclusively that a change of pressure alone on carbon,—the contacts remaining unchanged,—*had no effect on its resistance.*

In one apparatus used for this investigation the ends of a Carré pencil were plated as before, and copper terminals soldered to the plated ends; the rod as prepared was placed in a glass tube, set up vertically, and weights were applied; the terminals being connected with the bridge, *no visible change occurred* in the resistance, although a pressure equivalent to 300 atmospheres was placed on the carbon before it broke by buckling. Several carbons were tested in this way, but invariably with the same result.

Thinking that possibly the connections might not be

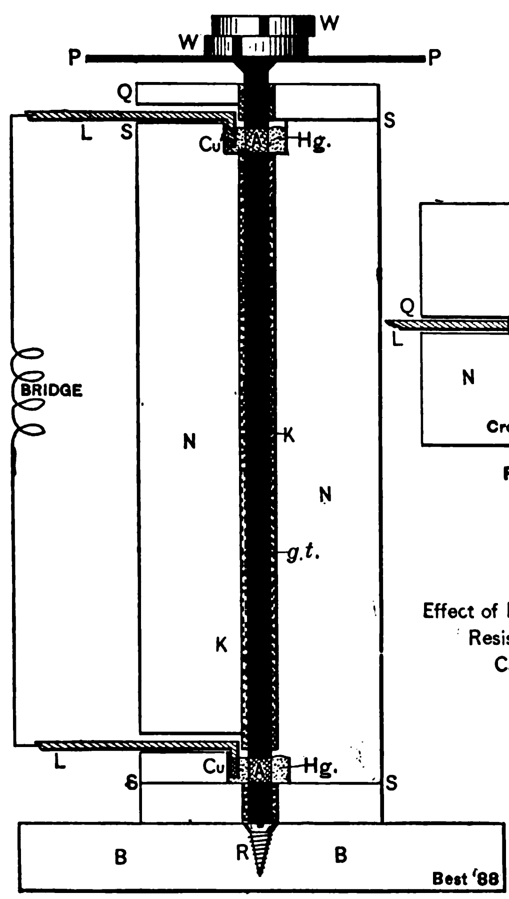


Fig. 10.

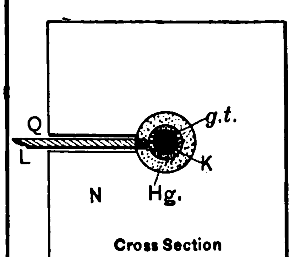

Fig. 11.

Effect of Pressure upon Resistance of Carbon.

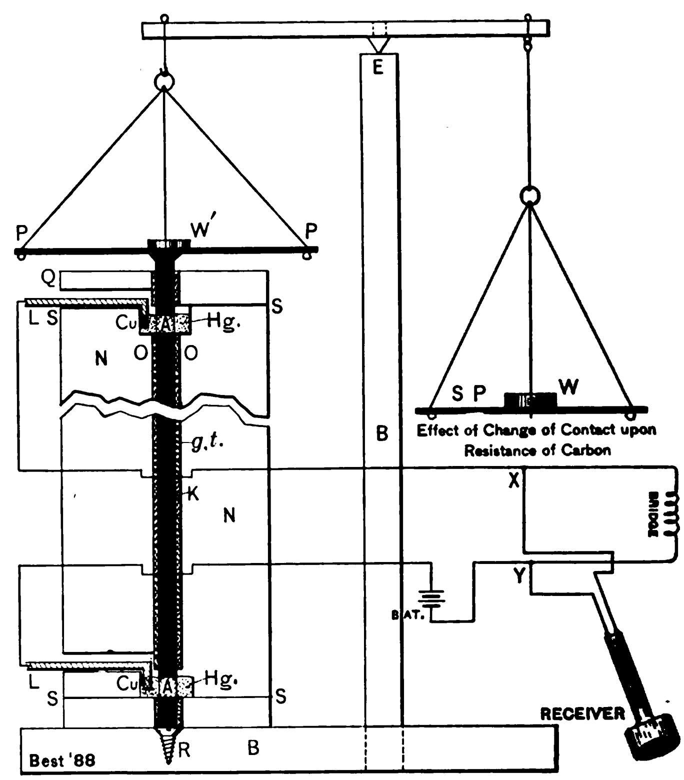

Fig. 12.

invariable, I devised the second apparatus as illustrated in figures 10 and 11. The carbon K had rings of copper plated around it at A A; a block of wood, N N, was bored through, so that a glass tube, in which the carbon just fitted, could be inserted, snugly fitting. The block was sawed through at S S, and copper cups, *cu cu*, inserted so that when the ends cut off were replaced and glued fast the cups would surround the plated portions of the pencil. Holes in the bottoms of the cups the size of the carbon allowed it to pass through. Holes were bored at Q to allow leaders to be inserted; the cups being filled with mercury gave amalgamated, unvarying connections. A plate, P P, soldered to the upper plated end of the carbon is for weights. Here, as in the other case, no appreciable change occurred in the resistance of the carbon, although pressure equivalent to 450 atmospheres was placed on the pencil. If the weights were suddenly removed no change occurred.

Mistrusting that variation in resistance of carbon usually attributed to *pressure* was simply due to variation of connections, I used this apparatus to investigate the question. The carbon was broken at O, figure 12; the weight of the plate P P and carbon from the plate to O was balanced by a scale pan and weight, W, as illustrated. The contact at O when the contact was good. The ordinates decreased very rapidly at first, but more slowly afterwards; in fact, if the rods barely touch at O, a fly walking across the plate P P makes an appreciable difference in the resistance, thus causing a variation in the current passing through the circuit; and if a telephone receiver be connected in place of the bridge, the fly may be heard to walk.

A carbon, whose resistance before breaking was 6.5 ohms, gave the following results, the weights being adjusted so that the resistance was just 20 ohms:

TABLE II.

SHOWING THE EFFECTS OF CHANGE OF CONTACT ON THE RESISTANCE OF CARBON.

Weights (x.)	Resistances (y.)
.125 gram.	15.356 ohms.
.25 "	12.166 "
.5 "	10.043 "
.75 "	9.368 "
1.0 "	8.746 "
1.5 "	8.385 "
2.0 "	8.005 "
3.0 "	7.724 "
4.0 "	7.542 "

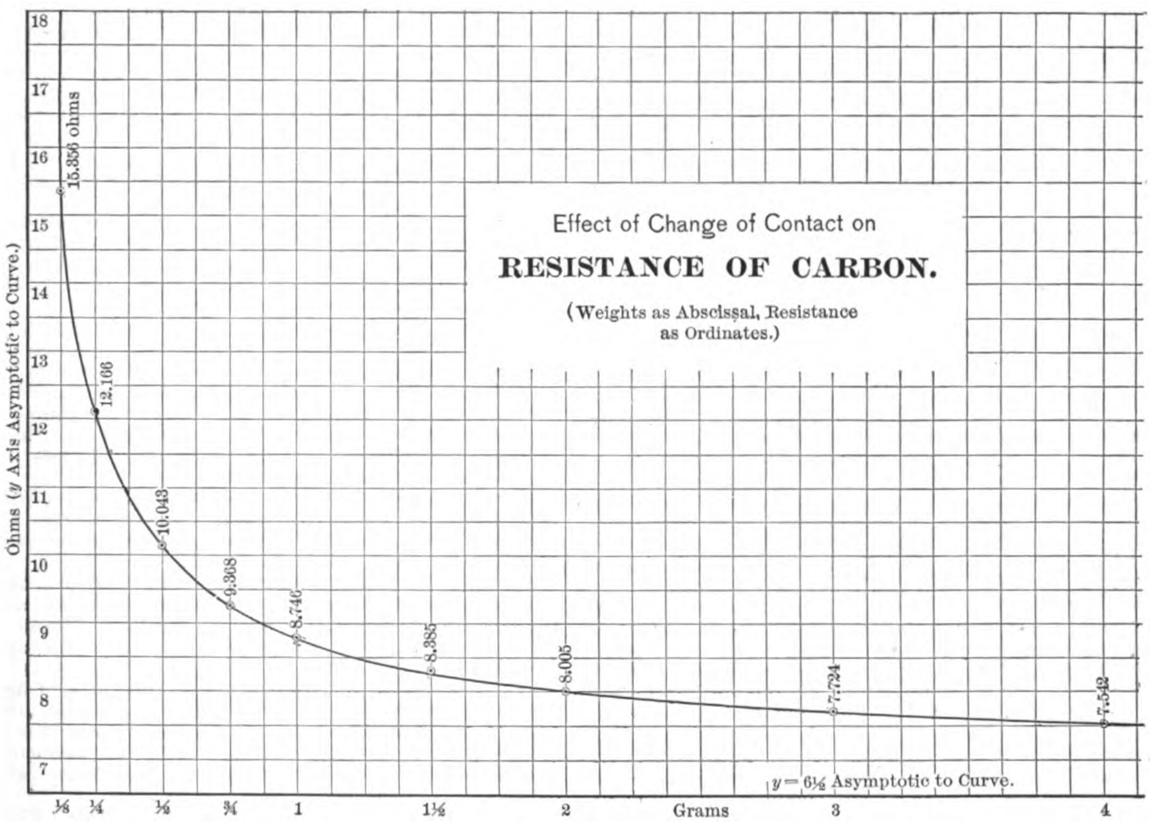

Fig. 13.

could be varied at will by weights on P P, while the other connections at A A remained invariable. It was found that the resistance varied from infinity, when the pieces were separated at O, to nearly the resistance offered by the pencil before it was broken; the resistance approaching the original resistance of the carbon as a limit as the weight on P P was increased. If x denotes weights and y resistances, the curve illustrating the changes would have as asymptotes $x = o$ and $y = R$ (R being the resistance of the carbon before it was broken). The experiment proved conclusively that change of resistance usually attributed to pressure, causing change of state, is due entirely to change of contact, as would naturally be expected. These results agree with those of Professor Siemens.

It was found that very small weights at P P, when the contact at O was almost imperceptible, had much greater effect on the resistance than a heavier weight applied

The curve is shown in figure 13; the weight, with resistance of 20 ohms, was estimated to be .1 gram. If the weights were removed, it was noticed that the carbon did not regain its former resistance, there being a sudden recovery to a certain extent, then a slow change—stopping before reaching the previous resistance. It was also noted that the longer the weights were allowed to remain on the plate the less the resistance became, there being a sudden decrease on application of the (small) weight, but a gradual decrease afterwards, the change being more noticeable the first few minutes. These results agreed with those of Professor Mendenhall in this respect, and it is curious to note that the curve for changes in resistance due to change of contact resembles very closely that found by Professor Mendenhall in his study of the influence of time on the change in the resistance of a carbon disc of Edison's Tasimeter (see *Am. Jour. of Science*, vol. xxiv.).

THE SOLUTION OF MUNICIPAL RAPID TRANSIT.[1]

BY FRANK J. SPRAGUE.

THE presentation of this subject before the American Institute of Electrical Engineers for discussion seems to me most opportune. It is a question of great importance, and one for which a definite solution is fast becoming imperative. To those of us who believe that the solution is to be found in the application of electricity, it has a special significance, and I trust that what I say may bear fruit by starting a general discussion of the subject, not only among electrical men but the general public as well.

More attention is now being paid to the question of tramway traffic than ever before. The reason is not only the comparatively high cost of operation under the present almost universal system of horses, but also because the public are beginning to feel and the street railway men are beginning to see that it is a system behind the times. Laying all humanitarian questions aside the public demand a better and a more rapid service. Railway men want to give it, provided they can do so for the same or less money than they are now spending.

To quote from a New York evening paper:

"The rapid transit question has steadily pressed its way to the front of subjects demanding immediate attention, until it now stands in this city the foremost question of the hour.

"The fact is made evident by the eager discussion upon every hand of the very best means by which the end may be attained with the least possible delay. The total passenger traffic, that is, the total number of persons carried, of this city, has increased at the rate of over 140 per cent. in each period of ten years since 1866, and is now something over 325,000,000. At the same rate of increase it would amount in 1890 to over 500,000,000, and in 1900 to 1,225,000,000."

There is every reason to believe that the through traffic will increase as much as expected, because the city is growing rapidly and its business section is continually enlarging and pushing northward, forcing the larger part of the population, especially the laboring classes, to seek homes in the upper portion of Manhattan Island and the annexed district, where rents, already increasing because of the increased facility of access, are still lower than can be readily commanded for business purposes in the lower part of the city. The elevated roads of this city, although carrying 500,000 people a day, do not answer the requirements of rapid transit, either local or through; nor is it possible for any two-track railway to do so.

By rapid transit we do not mean merely through transit; we ought not to consider alone the methods of transportation from one end of the city to the other, or from the city to the suburbs; we are likewise called upon to find some means by which the local traffic shall be benefited. Everything which lessens cost of operation, increases speed, reduces intervals between cars, increases the number of cars and makes extensions possible, aids rapid transit, no matter whether surface, underground or overhead.

With the same cost of operation, provided the motive power is materially cheapened, a greater number of cars can be run, intervals can be shortened up, large cars can be run in the place of small ones, better attention can be afforded, cars can be better heated, lighted and cleaned; they can make better time, people can be carried further for the same money, branches can be opened in districts which would otherwise not pay, and what is all important, more passengers can be carried, and for this reason alone more money can be made. For years an attempt has been made to replace the horse with motors of various descriptions—compressed air engines, fireless engines, hot water and soda motors, naphtha and petroleum engines and steam engines. But we can safely say that the question has to-day narrowed itself down as between the cable and the various electric systems for surface work, and between electricity and steam for elevated or underground work.

In order that we may be in a better position to judge of the comparative economy and the relative advantage of present and proposed methods of traction, I will briefly consider, first, the use of horses.

Two distinct methods are recognized among street car men in the handling of their stable equipments. In one, the stock of horses is kept as low as possible; they are worked hard, making 14 or 15 miles a day, and the depreciation is very heavy. In the other the stable equipment is increased; the horses are kept in excellent condition; their average daily duty is reduced to 10 or 12 miles, and the depreciation is lessened.

Assuming the cost of a horse as $150, and the cost of feeding and caring for him as $180 per annum, it would seem that any accurate knowledge of the average life of horses under different day's duty would soon determine the proper amount of the latter.

All railway returns do not, strange as it may seem, give accurate information on which such estimates of cost can be made; but from such facts as are given we may deduce the following: Taking the returns for 1887 for the five largest roads in Massachusetts, we find that they show 6,909 horses and 1,410 cars; that the mileage made was 12,884,665, and the passengers carried, 76,187,842.

Dividing the average daily mileage by the number of horses, and multiplying the number of horses in a team, we find only 10.26 miles as the average daily duty for all teams, sick or well. Horses which are on duty make from 12 to 14 miles.

On the West end road of Boston, which is now the largest street railway combination in the world, having about 212 miles of track and over 8,000 horses, 10 per cent. of the horses are counted as being off duty from illness, sprains, shoeing or other causes; and the balance of the horses average about 12 miles a day. A car day is estimated at 10 to 11 hours, and from 45 to 50 miles, and eight horses are allowed as the active force.

The rule given me by one of the officials of this company as a fair one to determine a stable equipment is, to divide the total daily mileage by the miles made in a car day and multiply it by nine, adding what is necessary for hill horses. Hence, if 50 miles is a car day duty, a daily run of 1,600 miles would require a stable equipment of 288 horses besides those for hill work.

On the Fourth avenue line in New York, the stable equipment is determined as follows: A car day is 11 hours, and eight horses make about five trips, aggregating about 50 miles. To this number is added 10 per cent. for illness, sprains, etc., and 10 per cent. for emergencies. On this road is illustrated the influence of an important factor in horse car work—that is, the position of the stables. Horses from the upper stable are limited to 11 miles, or otherwise they would have to make 22 miles, while horses from the lower stable have to make about 13½ miles, or considerably more.

The average cost of motive power per car day throughout the United States, that is, for from 10 to 11 hours and trips aggregating from 45 to 50 miles, is about $4. This counts only those horses on actual duty on the road. The cost of motive power per car day for equal mileage in Richmond is less than $2 on the heaviest sort of grade work. The total operating expenses of a horse railway average for the five largest roads in Massachusetts, 25.15 cents, and for all the roads in Massachusetts 24.7 cents per car mile; and the ratio of operating expenses to gross receipts is, for all the roads, 86 per cent.

The cost per day per horse, based upon the returns of four of the largest roads in New York, is 54 cents, and the cost per car mile from 9½ to 10½ cents per car mile.

In addition to the regular depreciation there is ever present, danger of an epidemic in hot weather.

Since the cost of the motive power alone—that is, the cost of harness and stable equipments, horse-shoeing, renewals, provender, hostlers, etc.—is 40 per cent. of the total operating expenses, it will at once be seen how vitally important any material saving in the cost of motive power becomes. If, as we claim, the cost of motive power in an electrical system is one-half or less than that in a horse system, the percentage of gross receipts available for interest and dividends is more than doubled.

Furthermore, when we remember that the average running time for horses is only five to six miles per hour, we have another reason which constitutes an unwarrantable objection to the uses of horses for rapid transit.

Among the systems which has been proposed to take the place of horses and which has given the most promise, and met with the greatest success where heavy grades and traffic exist, is the cable system. With its general features you are probably familiar.

There are, however, a great many objections. One of the most serious is the great initial cost of the construction and plant, the cost of the conduit alone ranging anywhere from $50,000 to $80,000 per mile of single track, making the investment so large that none but roads having heavy traffic can permit of the expense.

The conduit is necessarily large and costly in order to accommodate sheaves of sufficient size to prevent too great a loss in friction, and on account of the position of the cable and pulleys it is difficult to clean it. This large size also makes it difficult to construct a conduit which will not, because of the traffic and weather strains, be distorted and have the slots forced together or apart. The depth varies from two to three feet, more often the latter, and in any city street this is almost certain to interfere with steam, gas, or water pipes.

Each section of the line being a unit and operated from one cable, a break in the cable will suspend the entire traffic of that section.

A broken strand is apt to foul the grip and pile one car on top of another, as happened in Philadelphia, or suddenly start a car which is at rest, as recently happened on the 125th street line in this city. The cable is a heavy, cumbersome affair, 1¼ inches diameter, and weighs about 13,000 pounds to the mile.

It is found that it is best to make these cables in 20,000 ft. lengths.

If a cable is stranded it cannot be used until repaired; if it is stretched 1 per cent. it is considered unsafe. These weaknesses of the cable system render it necessary to have a duplicate cable ready for instant use, and a double line of sheaves.

1. Read before the American Institute of Electrical Engineers, June 19, 1888.

With a full load, not over about 20 to 25 per cent. of the power of the engines is actually used for the propulsion of the cars, the balance being for moving the cable. With any light load the efficiency is even less. But it has been found advisable to have even greater power than this, most of the companies having from two to four times as much engine power as is required at any time and, from one and a half to twice the boiler power. This is necessary, because if any part of the cable engine breaks the whole section of the system is disabled.

Every turn in a cable brings a strain upon the grips and reduces the life of the cable, and any increase in the speed at which a cable is driven likewise shortens its life.

Difficulty exists in turning corners, expensive drums, and oftentimes auxiliary cables being required. Constant care and attendance is necessary in lubricating the carrying and curve pulleys, and in taking care of the slots and switches, the estimates for Boston being about $3.20 per day per mile of single track, requiring the time of one man per mile. It is impossible to work turnouts, cross-overs or sidings without auxiliary cables, or to operate single tracks.

A line once being put in, any extension is expensive and difficult because of the terminal machinery which is necessary and the definite length of the cable.

The speed is limited; a car cannot travel faster than the cable and thus recover lost time, except on down grades; nor can it travel more slowly save by permitting the cable to slip. The regular speed then, must be the same in the most crowded sections of the street as in the less populated sections.

The starting is often with a jerk, and the whole motion of a lurching, unequal, unpleasant character, exceedingly disagreeable when first experienced.

Success in the cable railway system considered by itself depends largely upon the condition that a line of reasonable length shall be so located as to warrant frequent car service.

The chief advantages of a cable are, the cheapness, as compared with horse-power, of operating a heavily patronized road at a comparatively fixed rate of speed with no regard whatever to grade or gravity; but this cheapness is not inherent to the cable system, but due rather to the fact that steam has such a tremendous advantage over horses.

The motive power operating expenses vary from 50 to 70 of the cost of operating by horses.

Now, what is it electricity by some of its systems promises us for the ordinary street traffic? What are its advantages? First, it will do the work, and in a far more satisfactory manner and at a greatly lessened cost of operation than with horses. Electricity is simply an agent for which we have to pay a certain proportion to carry the power of our steam engines to take the place of the horse. Since not only on levels but also on the up and down grades an electric car can be run much faster than a horse car, and because it can be gotten under way and stopped much more quickly, the mileage with any given number of cars can be increased, the mean running speed increased and, the same time intervals made with a less numbers of cars; or on the other hand, shorter intervals be made with a given number of cars. The equipment will occupy about 35 per cent. less space, the horse space being saved, and this fact, together with the ability to back when necessary, and to quickly gain headway, enables an electric car in narrow and crowded streets to work a passage through where horse cars would be at a dead stand still. Not only can cars run down grade faster, but also with much more safety, because of the possibility of the instant reversal of the motors in the event of the parting of the brake chain, and when arriving at the top of a grade, the faster the motor runs the better. It has not got to be held in to save it.

The riding of an electrical car is far easier than that of any cable or horse car, starting and stopping more easily, and being in a large measure free from lurching and oscillation. The cars are much cleaner. They can be brilliantly lighted, and they can be heated by electricity. There is no dust such as rises from the heels of horses. The sanitary conditions are entirely altered, and the health and comfort of the whole population is conserved. Stables with all their unsavory characteristics and the consequent depreciation of the value of adjacent real estate disappear. No sand is needed on the pavements, and the pavements are not so quickly worn out; often no centre paving is necessary. It becomes feasible to operate branch lines, and also combinations of grades, curves, and ill-conditioned streets which would be prohibitory to any other system. It is not to be claimed that any one system of electric traction has all these advantages; but in some form or other they will be found.

It has been said that an extended system cannot be operated by electricity, that the lines may break down, that a large number of cars cannot be operated simultaneously, especially when bunched up, that wires burn out, that brushes burn up.

True, these things have happened, and in case of defective workmanship or carelessness they may happen again. Although electricity is a force of unknown nature, and we know it by its effects, it is a folly to hold that whatever faults in machinery may exist or accidents occur do not come within a very narrow and limited category; and powerful and mysterious as it is, and answering an impulse with the rapidity of lightning, it is at the same time the most tractable and law abiding agent with which we have to deal.

There is not a freak of which it is capable which we can not guard against. It has not an attribute of which we cannot make positive use. It has no power of damage which cannot be controlled.

The development of its application, the mistakes which have been made and the accidents which have occured are but the mile-stones and guide-posts of the highway to success.

Were it not for the occasional failures there could be no advance.

As a matter of fact there is no apparatus for the transmission of energy that compares in simplicity and efficiency with the dynamo-electric machine and the electric motor. There is no machine in existence which, when thoroughly and well built and decently cared for, is less liable to get out of order, and will stand harder usage and greater variations of work with a minimum of attendance and care. A motor has but one moving part, and that has a rotary motion. Its torsional effort under given conditions is a constant, and when properly built and proportioned some types have over a wide range the remarkable and unique quality of having this torsional effort vary as the square of the current used, a feature of marked importance in traction work.

As modern as the motor is, the peculiarities of all its phases are just as well known and capable of just as graphic representation and forecast, as are those of the steam engine. This can best be shown by reference to some curves which illustrate the characteristics of some of the Richmond motors, and have the same significance that an indicator diagram has for an engine.

For convenience these curves are plotted on both sides of the axis (Fig. 1). The ampere turns on one leg of the field magnet are plotted as abscissæ. The curve *O A* gives the characteristic of the machine when run as a series dynamo on a variable external resistance at 856 revolutions. *B C* represents the equation of counter-electromotive force with an initial electromotive force of 400 volts. I have allowed an increase in the actual resistance of the machine of 10 per cent. for heating and other causes. The speed of the armature, the miles per hour made by a car with the Richmond gearing, the tractive effort in pounds for one motor, and the horse-power units are, for convenience, all laid off as negative ordinates. Equal units of horse-power and torque are laid off as abscissæ, so as to make the maximum points coincident.

The first important curve which we have to get is the speed of the motor in terms of its current. We have the law that the speed is directly proportional to the counter-electromotive force developed, and inversely proportional to the strength of the field. In other words, the speed curve, *E D C*, in terms of the current, is plotted from the curves *O A* and *B C*, and the speed for any current is found by multiplying 856 revolutions by the ratio of the ordinates corresponding to that current.

The next curve with which we have to deal is that of the work of the motor in terms of the current; that is, the curve *O F C*, which intersects the axis of *X* and at the same point as the curves of speed in terms of the current and the counter-electromotive force.

A third and most important curve is that of the work of the motor in terms of its speed, which is the curve *O D G* plotted from the curves *E D C* and *O F C*, with the horse-power units transferred to the axis of *X* as abscissæ. For instance, following the negative ordinate for 30 amperes, we find, at the proper intersection, a speed of 630 revolutions of the armature, or 4.82 miles per hour of the car; and, at the insection of the work curve, that 11.65 h. p. is developed. These two values give us the point *S* as one of the points of the work curve, and so on.

Referring to the work required to be expended on a car, we have from the formula—

$$\text{h. p.} = \frac{w\,n}{335}\left(\frac{k}{2000} \pm \sin\,\theta\right)$$

where w = wt. in lbs.,
n = miles per hour,
k = resistance to traction in lbs. per ton on level.
θ = angle of grade,

the work which is required for any grade, speed and weight. Hence for any given conditions we can plot the equation h. p. = $a\,n$, and by its intersection with the curve *O D G*, find at what speed the car will be moved by the motors and what current is required, if we know the gearing. On the other hand, if we assume that a certain load on a certain grade shall be handled, and we elect that it shall be done with a certain efficiency of the motor, or on a certain part of the work curve, we can draw the car curve for this intersection and then deduce the speed of the car and, from it, what must be the ratio of gearing to enable the car to be handled by the motors under these conditions. Four of such car curves are drawn—*O R*, which shows the maximum which could be moved; *O M*, which shows what can be done at 50 per cent.

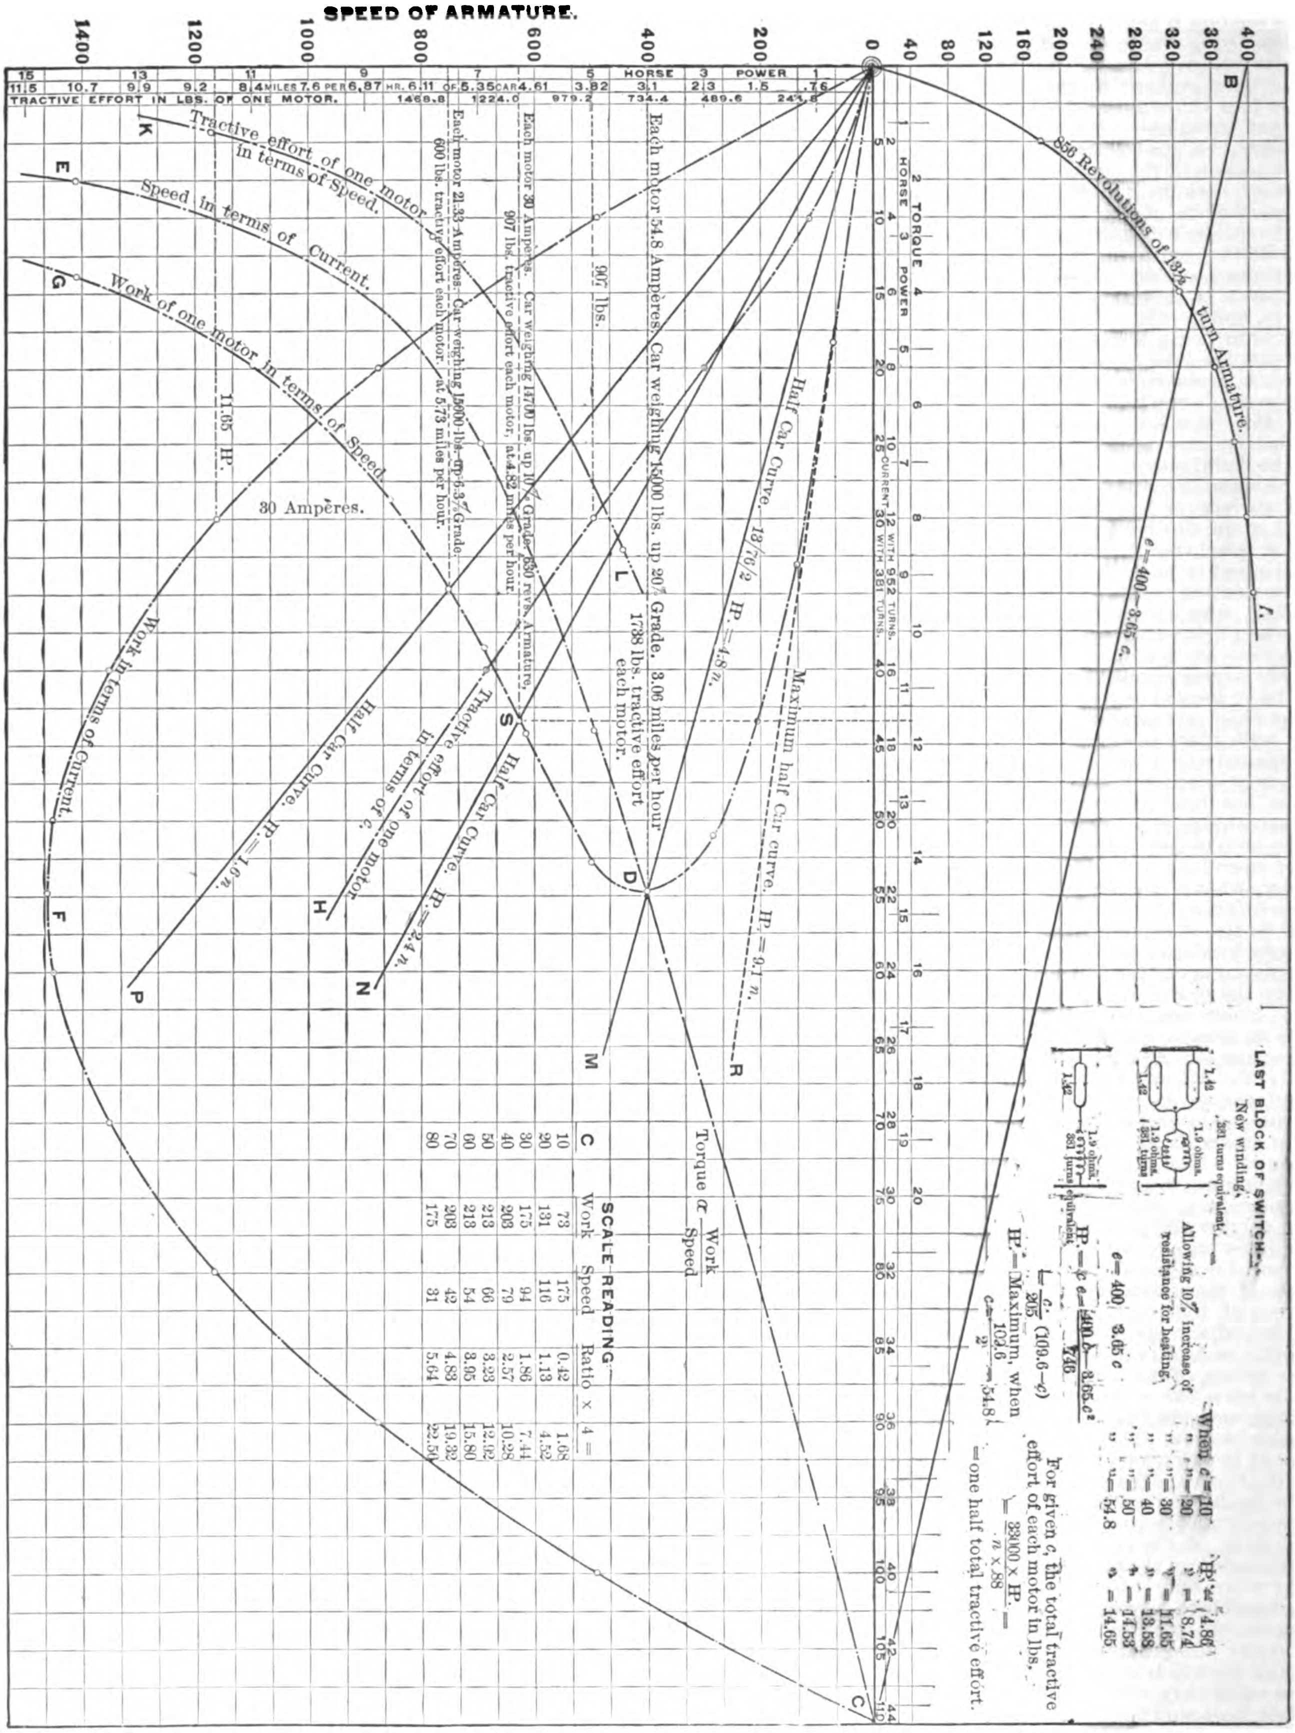

FIG. 1.—Curves Illustrating Electric Railway Motor Characteristics.

efficiency; *O N* and *O P*, showing the equations which are constantly in practice.

In the actual computation 10 per cent. extra is allowed for losses from friction and so forth.

With the Richmond gearing, and a car equation of h. p. = 4.8 *n*, we would have a car weighing 14,700 pounds sent up a 10 per cent. grade at 4.82 miles per hour, and each motor would take 30 amperes of current. If the grade or weight were increased, the curve *O N* would be carried toward *O M*; or, if the ratio of gearing is changed, then, with the curve *O N* in its fixed position, the weight of car or grade could be increased, although the speed of the car would be reduced. Other curves are shown, *L K* showing

the tractive effort of the motor in terms of its speed, and OH showing the tractive effort in terms of the current; the tractive effort varying, of course, as the work divided by the speed.

The variety of problems which can be worked out from this curve sheet is very large, and they become of vital importance in dealing with any new work. Nothing could show more clearly the value of a mass of iron in the field magnets (as I have always held to be the proper method of building motors), and the exceptionable qualifications of motors for tractive purposes. Any change in the switch or any change in the potential will vary these curves materially. One fact, however, is to be noted; no matter how the field may be changed, the speed of the motor at 50 per cent. efficiency is a constant.

The connection of the motor to the driving wheels has been attempted in a great variety of ways, and nearly every mechanical device possible has been used. Often the motors are carried upon the car body and connection made with the wheels, which should bear a variable position relative to the car, by means of friction wheels, sprocket-wheels and chains, or by belts, ropes or wire chains with tightening devices. The motor armature has been mounted directly on the axle, and also hung on a frame between the axles, being connected to both wheels by cranks and side rods, necessitating equal speeds of revolution of the motor armature and the wheels.

These methods are all crude and unsatisfactory. They are makeshifts, and ignore the most important and essential facts which have been developed in car and motor construction. There is to my mind only one good way to connect a motor, and this is to centre the motor upon the axle, supporting it flexibly from the car body or the car truck, and driving by gearing with one or two reductions according to the service which is demanded. This is the only way in which an absolutely safe and positive connection can be depended upon both for ordinary work and for the normal and sudden strains called for in an emergency.

Properly made, the friction of this method of reduction is very low, the motion is smooth and free, and reasonably noiseless.

The proposition to couple the motor so that it shall make the same number of revolutions as the axle, ignores one of the most important points which makes light weight in motors possible, and that is the high speed at which the armature can be run.

I have pointed out, in describing the curve characteristics of a motor, one of the essentials to determine the proper ratio of reduction for any motor when required to do a given work. I may here add a brief formula, which will also serve as an index in this matter: Let f equal the maximum velocity in feet per minute at which an armature at any time is allowed to travel; n the number of miles per hour to be made by the car; D the diameter of the car wheel in inches; d the diameter of the armature in inches. Then the ratio of the gearing must be expressed by the equation,

$$R = \frac{f D}{88\, n\, d}$$

For instance let $f = 4{,}000$, $n = 12$, $D = 30$ and $d = 10$; about the values which exist in street car work. Then

$$R = \frac{4{,}000 \times 30}{88 \times 12 \times 10} = \frac{125}{11},$$

and this should be made in two reductions. As in our largest trucks, let $f = 4{,}000$, $n = 35$, $D = 42$ and $d = 18$. Then

$$R = \frac{4{,}000 \times 42}{8 \times 35 \times 18} = \frac{100}{33}.$$

In the application of electricity we are limited to no one system; we have a choice which will permit us to meet any exigencies or conditions of traffic. There are two kinds of application.

In one each car is perfectly independent of the other, receiving its charge at the central station and acting as an individual unit. The storage battery method is such a system.

The other is a system of direct supply, and, unlike the battery system, where the energy of the steam is four times converted, it suffers only two losses. In this system the current is delivered directly to the line, from which the motors as they move along derive their current. There are several forms of conductors, centre and side rails, the main tracks, conductors carried in conduits, and overhead. Either a complete metallic circuit may be used, or one conductor with the rail and earth return. The machines can be operated under three different systems—the series, multiple series, and parallel circuit distribution.

Of these various plans, I shall discuss only three—the storage battery, the conduit, and the single overhead wire system with underneath contact carried on the car, and for the systems of distribution the parallel circuit system only.

The storage battery from the time of its first introduction to the public has offered a tempting solution to the application of electricity for surface transit. The great advantage of the battery system is that while most of the advantages of an electric system are retained, such as perfect control of the car, ease of manipulation, cleanliness and so forth, each car in itself becomes an independent unit not dependent upon any general accident to a system. As attractive a solution as the storage battery at first sight seems, there are many points of disadvantage in the present state of its development. One of the most important is the excessive weight of battery which is necessary under the conditions of service which are met with in this country, from 3,400 to 4,000 pounds being the ordinary weight. Not over 10 per cent. of the lead in these batteries is actually used for storage. On account of the weight and the room which the battery takes up, there has to be a radical change in the construction of the cars, and while old cars can be made use of by a great deal of patching, it is not advisable to attempt this. This change makes the present cars useless, and likewise increases the cost of new car bodies.

Then again, while the tracks as they exist may stand the additional weight of motors on a four-wheel car, the additional weight of battery, making the total weight on a given wheel-base double what it was before, will render it necessary on a great many tracks to relay the road-bed, or to put in 8-wheel cars. Of course these objections are not so serious on a new road as they are on an old one.

But I confidently expect to see, in the not so very distant future, the weight of battery necessary to handle a car reduced one-half; this, besides overcoming some of the objections which exist now, will halve the expense of handling them at the central station, and will also allow the present standard width of aisle to be maintained.

The present excessive cost and unknown depreciation of the battery, its lack of efficiency, limited capacity, the fact that only a portion of the charge can be taken out with safety, and the reduction of its output when sudden demands are made upon it, are all of such a character as to leave wide room for improvement. The loss of efficiency in conversion I do not esteem of such vast importance, because, in any large system where the engines are kept going under a steady load, the cost of operation will not be so very much more than where operating under continually varying loads. The limited rate of discharge, as well as the limited capacity, limits the grade work to which a battery car can be subjected. For instance, as batteries and cars are now made, we can easily have the following combinations of weight:

	Pounds.
Weight of car...	5,000
Batteries...	3,600
Motors and other apparatus ...	2,000
Sixty-five passengers...	9,100
Total...	19,700

To start and to accelerate this load on, say a six per cent. grade, demands a discharge rate which no storage battery company cares to recommend.

As near as it is possible for us to get at a correct estimate, on a new road of moderate grades a storage battery system could be operated at about 80 per cent. of the cost of operation by horses. This is about double the cost of the direct system of supply on a large scale.

But the storage battery is not going to stand still.

Many men with abundant capital are striving for improvement, and I think there is but little question that batteries will be reduced in weight, increased in capacity, and made far more efficient and long-lived.

The conduit and overhead systems have one point in common. Both are dependent upon a central station, and the actual cost of operation (except for the care and maintenance of the conduit itself) would be about the same. There is, however, a great difference of investment. Both must have about the same amount of copper, and, to be effective, about the same distribution.

The difference of cost then is practically the difference between pole erection and conduit laying, and this will be from $25,000 to $30,000 per mile. As an investment, of course it means that with the conduit very much more money has to be earned. The electrical conduit can be built for less money than a cable conduit, because it can be made of less depth, but it cannot be built without due regard to the strains of street traffic and weather, and with proper drainage and cleaning facilities. The advantages of the conduit are chiefly that there are no overhead obstructions. Its disadvantages are, besides its great cost, the lack of cleanliness, increased possibilities of leakage, and greater difficulty of repair in case of accident. Recognizing, however, the demand which exists in certain places for a conduit, we have developed such a system which has many of the same elements of simplicity and reliability that our overhead system possesses.

The working conductor carried in the conduit is divided into sections, which at intervals of every block or half block, as desired, are connected through automatic cut-outs in man-holes to the main conductor, which is continuous and enclosed in a lead or iron covered cable. Any accident to a section, such as flooding, short circuiting, and so forth, will simply cut out that particular block.

For the immediate solution of the question of more rapid and cheaper transit, in many places the overhead system is most available.

I am aware that a great hue and cry has been raised, especially

of late, against any electric wires whatsoever being used above ground. The feeling which exists is not entirely unreasonable; in fact it is easily accounted for by the most casual inspection of the condition of the wires of this city. But many of the objections which are raised against all overhead systems are not necessarily inherent; they are very largely due to gross carelessness in construction, engendered by a faulty municipal administration. We have in our cities little or no active control or oversight of the wires which have been put up in our streets. Year after year, from the earliest telegraph days, those in control have granted to telegraph, electric light, telephone and electric power companies innumerable more or less limited franchises for stringing or hanging wires through our streets. These permits have often been granted without any restriction whatever; they are often granted for a "consideration." The erection and maintenance of these lines being a large factor in the cost of construction and operation of the companies, they have been put up with little or no regard to public convenience or safety—certainly with no regard to any æsthetic tastes—and oftentimes with an utter ignorance of the proper methods of construction. Fire underwriters, in their wisdom, have demanded an insulation to stand fire, forgetting, or in apparent ignorance of, the fact that protection from moisture and leakage is of far more vital importance. Hence we have that treacherous wire known as "underwriters' wire," or more commonly among electricians, "undertakers' wire."

The poles have, until lately, been of the cheapest construction, badly set and continually marred and weakened by the spurs of the linemen. New lines have been continually added, and poles intended originally for a certain number of wires are now carrying double or treble that number.

The electric light companies, after cutting out a lamp for which a contract has expired, leave the bights of their wires hanging in loops. The telegraph and telephone companies allow thousands of miles of "dead" wires to remain overhead, or to hang in festoons from every pole, which in some sections are utilized as clothes lines or are used by the street urchins as kite traps.

They cross and recross the streets at every angle, every elevation, and at every tension. They are strung surreptitiously on poles to which no right exists, and over buildings for which no permit has been granted.

No one seem to have the power to compel a change or improvement in these practices, and the companies themselves never will do it until so compelled. The sharp competition in the lighting business, the small profits derived therefrom, the great trouble of hauling down and getting rid of miles of dead telephone and telegraph wires, all these interfere with a satisfactory straightening out of the existing system of overhead wires.

In all improvements for public improvement we have to consider the arguments for as well as against such improvements. It is not sufficient that we say that there are disadvantages attending the introduction of the system, we must consider likewise the possible advantages; and this is especially important when we consider the use of the overhead line in a system for propelling street cars. Such a line being part of an investment of a company which has practically no competition on its own street, and whose own interest would require it to keep its line in first-class condition, can be put up in a manner presenting few of the objections which are generally urged against a system of overhead wires. I would not urge its adoption for all places, but in all suburban districts, for comparatively narrow streets, for all streets operating under an elevated railway structure, or where the tracks are near a sidewalk, the direct system of supply from an overhead line with underneath contact, presents advantages which, once appreciated, far outweigh the possible objections of such a system.

Several methods exist in which the wires can be erected. One in which span wires, at a distance of 125 feet apart, reach across the street from building to building, or from pole to pole, and have suspended from them, directly over the track, at a height of about 19 feet, a longitudinal wire of not more than a quarter of an inch diameter, this wire being termed the "working conductor." This should be of the very strongest character. It should have a high elastic limit, great tenacity, and resist corrosion and oxidation.

Its conductivity is a matter of less importance, since not upon it, but upon the main conductor which supplies it do we depend for the main transmission of our current. Hence the elements of strength and reliability are of far more importance than conductivity. We have found that the best wire for this purpose, is that alloy known as "silicon bronze"—a wire which can be drawn for a tensile strength of from 75,000 to 150,000 pounds per square inch; that is a strength higher than that of the best commercial steel. Such a wire it is almost impossible under conditions of service to break, and its life is very long. Samples of hard drawn copper wire, which possesses only from one-third to one-fifth the tensile strength of this wire, show, after months of the severest usage, scarcely any signs whatsoever of abrasion, or reduction in size. This wire is of the same size whatever the distance run or the number of cars operated; and the main conductor may be stretched along the buildings, through a side-alley, along poles, underneath the elevated structure, or buried underground.

In the latter case there would be in a single track street only one longitudinal wire, and that one over the track, and it would be no larger than a single telegraph wire; and in the case of a double track, there would be only two wires stretched longitudinally along the street, and these would be as taut as harp strings.

Switches and cut-outs are put in main and working conductors in such a way that the different sections can be operated independently, and cut out automatically or at will.

The span wires can be as much above 19 feet from the ground as is desired. Of course, where a telephone or electric light line crosses the street and may break and fall upon such a conductor, it would be necessary to have one or two guard wires above it.

These guard wires can be very properly carried from the span wires themselves. Furthermore, if desired, the stretches between the span wires where the guard wires are used can be very much longer than 125 feet; they can be even as long as 500 or 600 feet—that is, two or three city blocks—in which case the two guard wires form a light suspending structure, from which, at intervals of a hundred feet, the middle wire is carried in a straight line.

In very many cases it is unnecessary to have any span wires whatsoever. In those streets where the track runs near the curb a light pole with an ornamental bracket is all that is necessary.

In a broad street where the tracks occupy only a small portion of the street, and are near together, a line of poles of ornate design with light arms projecting on either side can follow the centre of the street. Oftentimes there is a middle division or park, such as exists on the Boulevard in this city, which will afford space for the poles without interfering with anything.

These same poles can be used for lighting the street.

On streets occupied by elevated railroad structures, the structure itself can be used as a support for the overhead wires.

Among the numerous places in New York where an overhead system could be put in perfect operation are Eighth avenue, from Fifty-ninth street up; the Boulevard, from Fifty-ninth street up; a part of the First and Second avenue lines; the Third, Sixth and Ninth avenue lines, and all the suburban extensions in the annexed district.

To avoid any extra strain on this wire, the current is taken off by a flexibly supported trolley, carried on the car, and making contact underneath by upward pressure as will be more specifically described later.

With such a system put up in the proper manner, it is almost impossible for any accident to occur which will disable the line or prove a hindrance or annoyance to the public in any way.

The wires are perfectly clear of the operations of the firemen, and should they in any place interfere the obstructing section can easily be cut out without disabling the remainder of the system.

The question of "electromotive force," or electrical pressure, so to speak, to be used, is one of great importance. I do not favor going above 400 volts, and this on a continuous current circuit. This is less than one-seventh the electromotive force which exists on many of the arc-light circuits in this city; and the current being of a perfectly smooth and continuous character is free from the danger which might be feared from a current of equal electromotive force of the alternating or pulsating character.

In point of fact, in Richmond, a very large number of our men have received the full E. M. F., from our line without any injury.

On a dry day the trolley wire has lain coiled up on the ground while the cars are in operation; and while certain changes were being made in the overhead circuit, the men work continually with the current on the line. I have never known a constant potential current of 400 volts to cause of itself the death of or serious injury to a human being.

The past year to me has been one of great responsibility and wide experience. It has been a hard year. But the experience and expense are as nothing compared with the great value of having been, with my associates, instrumental in bringing to a successful issue one of the most important pieces of electrical engineering with which I have ever had anything to do. Among the roads which we have equipped the most important is, of course, the Richmond Union Passenger Railway, which now has six times as many machines in operation as any other road of its character in existence, at which every difficulty to be encountered in an overhead system on heavy grades and with sharp curves has been made, and which has for all time conclusively settled the question of the economical operation of a large road by the method of direct supply.

I will briefly refer to the road, giving some illustrations of its principal features, and some facts about its operation.

Some idea of the character of the road may be gathered from the following: The total trackage is about twelve miles. It runs a very irregular course and reaches the principal parts of the city (Fig. 2). About nine miles of street are covered. The central section is a double track for a distance of something over two miles, a part being laid on paved streets, and the balance on macadam or unpaved streets; all the extension and branch lines are on unpaved streets, many of them in clay soil, which in wet

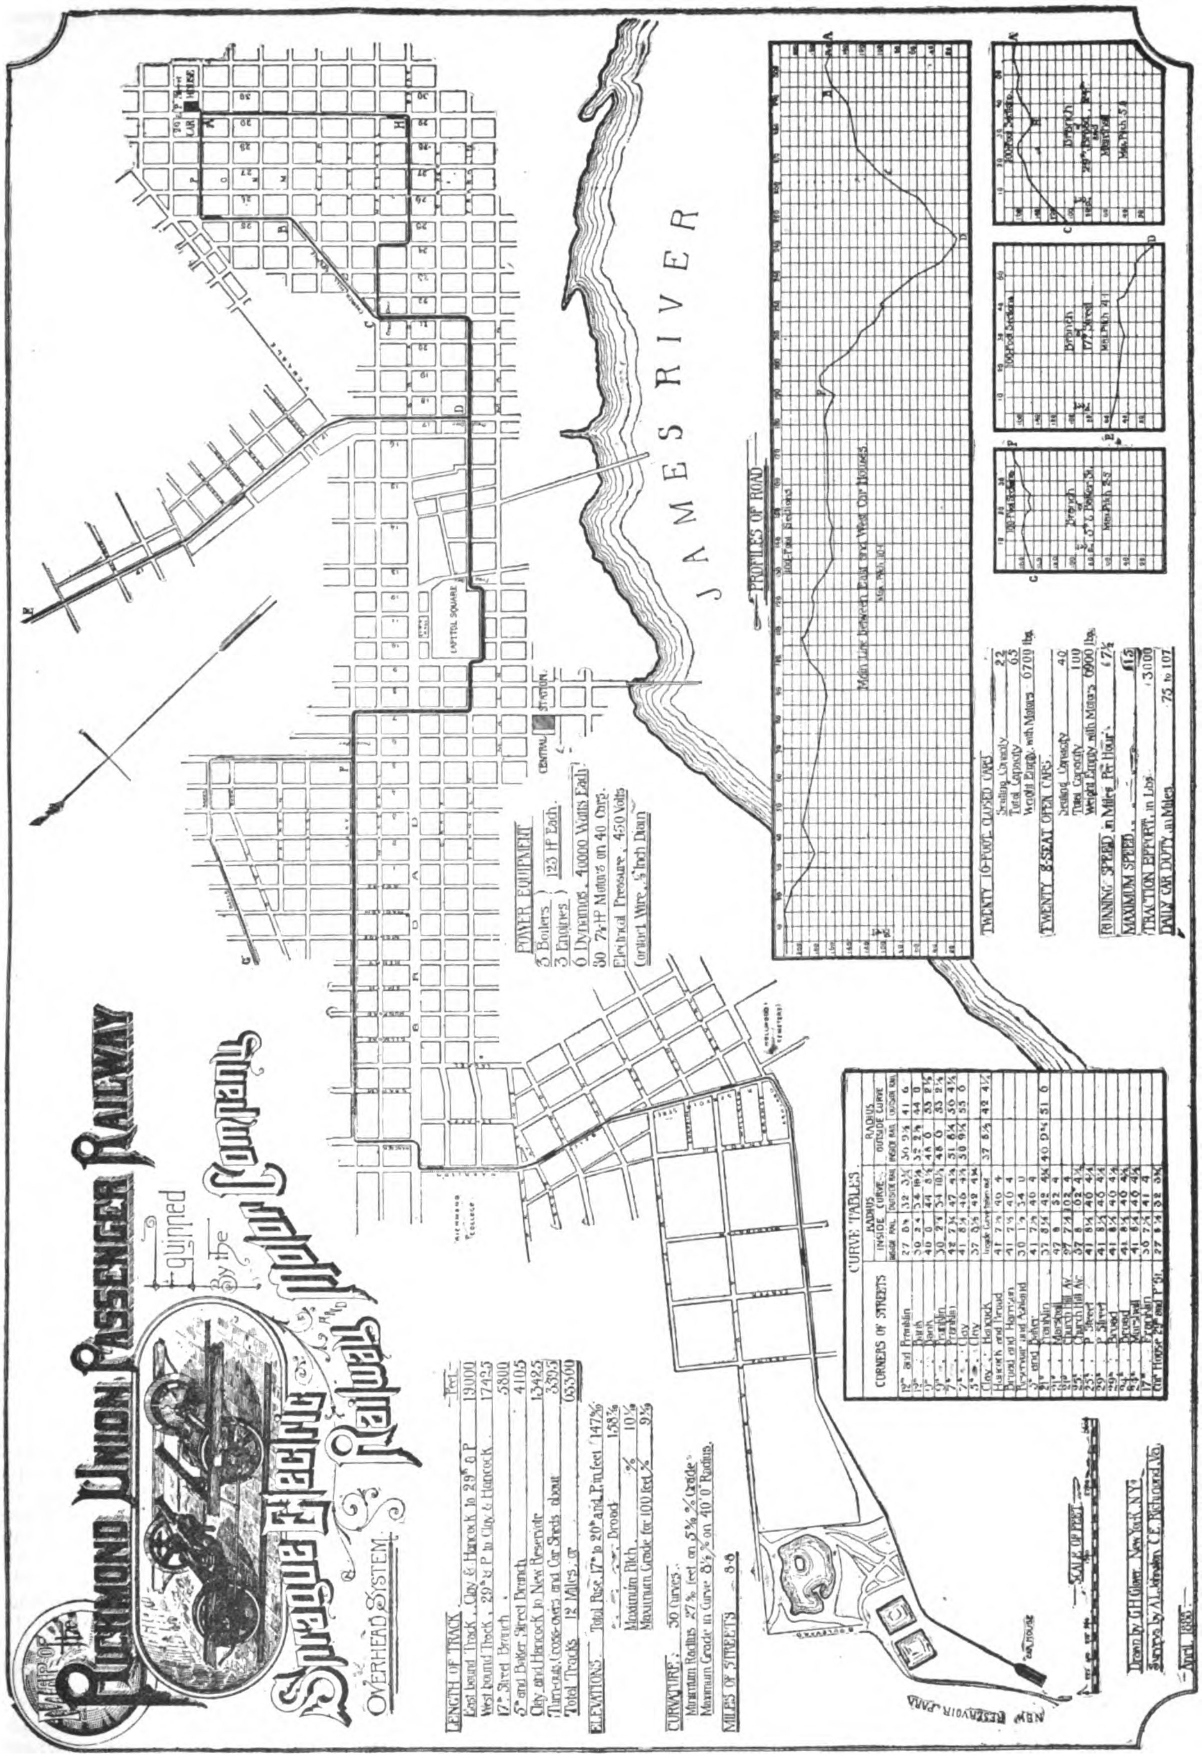

FIG. 2.—Map and Data, Union Passenger Railway, Richmond, Va.

weather covers the tracks, and where it would be an impossibility to operate horses without paving. The double track section partly encircles the old State Capitol and presents difficulties rarely equaled elsewhere. This part of the line in a distance of less than one thousand feet has on both east and west bound tracks, four curves, the inner rails of the west bound track being of about 27, 30, 40 and 50 foot radius. The power necessary to run these sharp curves is much increased by the fact that grades are encountered on the curves as high as eight per cent., and the lay of the street has required some of the outer rails to be some inches below the inner one. Running eastward from the Capitol the road descends to a low valley through a series of grades varying from three to ten

per cent., and then ascends a series of sharp grades and curves in a new district to one of the car houses.

Going west from the State House the road rises to nearly the highest point in the city, and then runs through a residential district across the Richmond, Fredericksburg & Potomac Railroad, and after several sharp curves extends back a further distance of two miles to a second car house beyond the new reservoir. Two branches connect with its main line, one leaving at the old Market Place crossing, and paralleling the Chesapeake & Ohio Railroad, and terminating at its machine shops. The other runs into what is popularly known as "Africa," a section almost exclusively inhabited by colored people.

The narrow streets, their hilly character, and the lack of paving, especially in the new districts, has made the road one of exceptional difficulty to operate. There are no less than twenty-nine curves requiring bent rails, the majority being of sharp radius, five being less than thirty feet. There are also several sweeps or curves of large radius, several turnouts and cross-overs. The grades are the maximum ever ascended in practice by a self-propelled car depending on track adhesion alone, and many of these grades are very long. Going east there is one section of almost continual ascent for about 5,600 feet, with grades varying from three to seven per cent., and going west there is a stretch of 1,900 feet, with grades varying from three to ten per cent.

When we first undertook to equip this road in the face of these difficulties, there was the additional discouragement of the ridicule of a great many prominent street railway men and car constructors as well as electricians. It was only a comparatively short time ago that one of the leading lights in street railway circles made a report to the street railway convention in which he stated that unless some new invention should be made it would be impossible for any self-propelled vehicle to satisfactorily operate under the ordinary condition of street car service. He, as others, held that the grades and curves met in practice were so severe and the condition of the track so bad that a car propelled by its own wheels could not under any possibility, day in and day out, be relied upon to move itself. One electrician even made the statement only a short time ago that any man who should attempt to operate on more than a six per cent. grade would lose his reputation.

Reliability, economy, simplicity of construction and operation on a scale never before attempted, and under conditions which we could not foresee. This was the problem, and perhaps it was well we did not know the difficulties. Then again, while there have been strong friends of the enterprise in Richmond itself, there was a class that felt anything but pleasure at a stranger's advent.

The change of feeling with which this enterprise has been regarded by this doubting element is somewhat significant. When the franchise was originally secured the city was blest by one car-line only, and this had dingy bob-tail cars drawn by mules, which, on the heavy grades characterizing the topography of Richmond, made very slow time. The new districts were not reached at all. When the present line was proposed there were not wanting philosophers who knew that no road would be operated. Even when the tracks were down these same wise-acres predicted that no cars would ever move over them, and most certainly if they did, the time-honored mule would be called upon for duty. Even after the cars were put on the line experimentally there existed but little faith that success would be reached. But times have changed. The mules on the competing line are to give way to electricity. The citizens of Richmond are the strongest friends of the electric railroad of to-day, and as regards the street railway community elsewhere, the work which the road has done and is doing and the acceptance of the contract, speak for themselves.

The difficulties we have met are many. One of the most annoying at first experienced was that the cars frequently jumped the tracks. A large portion of the track was, as has been stated, laid in macadam and dirt streets, the latter being chiefly in new districts and in a soil of which the chief component was red or yellow clay, and although the curves were of sharp radius, only one guard rail was used, and they were not bound in by paving. The winter months brought frequent and heavy rains. The tracks were found to be settling out of sight in mud, and especially at the curves they were spreading. The cars being large and heavy, with a 4 foot 8½ inch gauge and a 6 foot wheel base, helped to make the curves spread by the tangential pressure of the forward wheels on the outer rails. Mud and stones would get into the grooves, and the cars, having a tendency to go ahead instead of being pulled around by the head as with horses, would climb the track, and before an inexperienced man could check them the wheels were down five inches in the mud alongside the stringer pieces and the track brakes hard and fast against the tracks. Sometimes it was lifting, sometimes prying, and sometimes a heavy hard pull on the part of the motors to get them back again. Experience, however, is a great teacher, and among other things which has been taught is this: that money will be saved by a good track construction and the observance of a few practical points. All curves should be bound in and paved, and this has since been done in Richmond. They should likewise have two guard rails, because it is much easier to steer a car by its rear wheels by holding them in place, than by allowing them to crowd the inner rail and force the forward wheels to climb the outer one. In dry weather, with the large wheel base and sharp curves, it is found advisable to grease the grooved rails.

Another point which has to be carefully taken care of is the character of switch which is put in for sidings and cross-overs. If drop switches are used, they should be of such character as to allow the car to come down easily; tongue switches are now being put in on all the new work which is being done. It is a rare thing at present to have a car leave the track. I have seen a car in the winter propelled for a hundred feet off the track, and also leave and go back on its own account.

The power house is situated two blocks away from the nearest point of the line, and is almost equi distant from its extremities. As a distributing point, it is, therefore, both theoretically and practically, a central station In the construction no expense has been spared, and the performance of the station has justified it. The battery consists of three cylindrical return tubular boilers of the latest pattern, mounted on a Jarvis patent furnace, their capacity being 125 h. p. each. The water is taken from the city mains or from a well. All feed-water connections are of brass pipe. From the pumps the water passes first through the feed-water heater, where it is heated from 150 to 200 degrees F. From there it goes to the filter. The draft in the furnaces is regulated by an automatic steam damper regulator, which, with anything like regular firing, keeps a pressure within two pounds of that for which the regulator is set.

The boilers all feed into one main feed steam pipe, which in turn leads to a separator, a large iron cylinder into which the steam passes, the water falling to the bottom and the dry steam being carried off at the top. All live steam pipes in the boiler room are covered with magnesia.

The present battery occupies less than half the available space in the boiler room, so that four more boilers can easily be put up when it becomes necessary to enlarge the plant. Two more have just been added. An important feature of these boilers, which are the source of power of the whole system, should not be overlooked, that is, the quality of coal burned. Where a very perfect combustion is obtained a grade of coal can be used which would be impracticable in an ordinary furnace; the mixture at present being used is two parts screenings to one part bituminous, costing from $1.75 to $2 per ton delivered. As the station is only three hundred feet distant from the depots of three railroads, coal can be obtained almost at the door. From the boiler room, both the steam and exhaust pipes run in an underground, mineral-wool-packed trench to the engine room.

The railroad engines, of which there are at present three, are of the Armington and Sims high-speed type, and develop, when running at full load, 125 h. p. each at 250 revolutions.

Each engine drives two special Edison dynamos of 40,000 watts capacity each, wound for 500 volts maximum pressure. The dynamos feed into copper "bus" bars, supported on the walls by porcelain insulators.

Each machine has its independent ampere meter, and in addition there is a general ampere meter at the end of the positive "bus" bar. From this bar the current passes to four snap switches, each switch being connected through a three-plug safety switch block to one of the feeders supplying current to the main line wire. These four-feeder wires tap into the line wire at different points, thus maintaining the pressure approximately equal all along the line. At the ends of one of the feeders in the central station pressure indicators are to be attached which will indicate the voltage at the junction of one of these feeders with the main current wire, and this will serve as a guide.

The electric circuit consists of two parts—the overhead and the ground circuit, each being of compound character. Along the curbstones at distances of 125 feet are 30-foot poles, inserted into the ground a distance of five feet. Great difficulty was experienced at first on account of the clayey character of the soil, and it became necessary at the corners to put in very heavy poles, which were imbedded in concrete and stones to prevent settling out of place after heavy rains. These poles carry the main circuit which extends throughout the entire length of the roads, and is a copper wire three-sixteenths of an inch in diameter; this is called the main conductor, for on it depends the operation of the road in case of accidents or repairs to the contact wire.

The arrangement of main and working conductor are as already set forth.

This main conductor is, as stated, supplied at widely separated points by feeders, which come from the main supply at the central station. Without the use of these feeders, which can also be reinforced if necessary, the size and cost of the overhead conductors would be very largely increased. The curves are formed of a series of short chords, which approximate the central line of curvature.

The current is taken from this working conductor by a light structure on top of the car. This consists of a low skeleton framework which carries an adjustable swivelling trunnion, hav-

ing at its upper end a jaw in which is suspended a counterbalanced trolley pole, having at its extension a grooved wheel held by a spring against, and making running flexible contact with, the under side of the working conductor. The flexibility of this arrangement is very great, it being able to follow with perfect facility variations of the trolley wire two or three feet in either horizontal or vertical direction at any speed, and around any curve. What is all important, it relieves the line of strain instead of adding to it. When getting at the end of the track this trolley trunnion is swung around so as to trend in a proper direction abaft the centre of the car. If off the line it can be replaced from the car quickly and easily in the darkest night. From the trolley the current passes through a protected wire to the lightning arrester and thence to two switches, one at each end of the car, whence after whatever commutation is necessary, it goes to the motor circuits, and thence to the wheel frame.

The return circuit is through the track, and thence by both metallic and ground circuits to the station. Each section of rail is joined to a copper ground wire, which runs throughout the length of the road underneath or alongside the stringer pieces, which is to prevent appreciable differences of potential existing between the rails; as a further precaution, at intervals of 500 feet this ground wire is connected to an earth plate, and at seven points widely distributed, these ground plates are supplemented by heavy iron pipes sunk into iron ore, or 12-inch water wells, about 25 feet deep. The ground wire is connected to the station, and there is also a main ground connection made there in a 30-foot well through a large sink plate, and another to the entire waterworks system. Some modifications of the overhead system are now being made which will make it impossible for any accident to one section of the line to disable the remainder; will enable the different sections to be operated independently; and, in case of a fire which may necessitate the blocking or temporary disabling of one part of the line, will allow this section of the line to be cut out of action either automatically or at will.

Each car is fitted with a duplicate and very powerful motor equipment. This is carried entirely beneath the car body, is very compact, out of sight, and necessitates no radical change in the construction of the car. The body had to be stiffened a little and three-inch steel axles put in. One of the great objections which have been met with in applying motors, whether steam, electrical or of any other character, to the propulsion of street railways, has been the difficulty of getting sufficient track adhesion to operate the car under all conditions of track, loads and grades. Especially was this objection true in Richmond, where it was manifest that no application of a motor system could be fully successful unless the entire weight of the car and its contents was made available for traction.

One of the manifest reasons is, of course, the slippery character of the track under many conditions. Another thing should also be noted, and that is that it is almost impossible in practice to cast all wheels of exactly the same circumference, or at least so that the paths described by the lines of contact shall be the same. Moreover, on curves the wheels are all traveling over paths of different lengths. Theoretically, the wheels should be independently driven, but since this is not possible it follows that the next best thing is to drive each pair of wheels independently. It is a fact which admits of no dispute that there are conditions of track which will not permit of a car being driven from one pair of wheels only, and this difficulty is often augmented by the fact that if one pair of wheels only is used they will sometimes be leading, sometimes following; on heavy grades with one platform reserved for the driver there is a very serious displacement of the centre of gravity, and there may be very much more weight upon one pair of wheels than on the other. The whole experience in Richmond has been to emphasize the value and necessity of independently driven axles.

To accomplish this, one motor is centered upon each axle, and to allow the required freedom of motion, and at the same time to preserve perfect parallelism in the meshing of the gears, and also for taking part of the weight of the motor off the body of the axle and to throw it on to the journals, one end of the motor is supported by double compression springs playing upon a loosely suspended bolt, which is supported from a cross girder in the bottom of the car.

The motors are, then, so to speak weighted or flexibly supported from the car body, and the motion of the armatures is transmitted to the axles through intermediate gearing, of compact form and great strength, so that whenever the axles are in motion there is a spring touch of the pinions upon the gears. Barring friction a single pound pressure exerted in either direction would lift or depress the motor a slight amount, and no matter how sudden the strain, whether because of a variation of load or speed, or a reversal of direction of rotation, it is impossible to strip the gears unless the steady strain exceeds the strength of the iron, the pressure on the gears always being a progressive one. The motor armature makes nearly 12 revolutions to each revolution of the car axle.

The motors, although in one sense independent, are connected with duplicate switches at either end of the car which afford simultaneous control of both machines. These motors, which are of normal capacity of 7½ h. p. each, can for a short time work up to 30 h. p., and are capable of producing a tractive effort of over 3,000 pounds at 50 per cent. efficiency.

The machines are controlled by a single movement switch which effects the various commutations and reversals. They run with fixed brushes in both directions and under all loads. They are run without any covering, and I have no doubt of having street car motors in such condition soon that the cars will be run over a pit, and the machines washed down with a hose.

The cars can be run at widely different speeds, varying from the slowest crawl to twelve or more miles per hour. They can be started and stopped without the use of brakes in the space of three or four inches, and when making the normal running speed can, in an emergency, be stopped and reversed without brakes within less than a quarter of a car length. The starting, although prompt, is easy and without shock or jar.

Emergencies sometimes bring out qualities of motors which are unexpected, or which at least if counted on are rarely ever brought into play. On one occasion a man was descending a six per cent. grade with a heavy load when his brake chain parted. Seeing a sharp curve right ahead of him which he knew he would leave if he struck it at the speed he was running, he instantly reversed his machines and brought his car to a standstill, and on the rest of his trip handled his machines entirely with the motors. On another occasion a man passing from behind one car directly in front of another was struck and knocked down by the dashboard. Although the car was moving at a lively gait, the machines were reversed and the wheels stopped within a foot of the man. By any other method of propulsion he would have been killed. Frequently on a ten per cent. grade, with a loaded car, the brakes have been thrown off, the machines reversed, the car stopped and started backward up hill within less than one-half of its length, a test of the most remarkable severity.

In noting the control of the car, one is struck at the remarkable character of the traction, and cannot help wondering where it comes from; unquestionably it is in a large measure due to the fact that every pound of weight is available for traction, and that the two axles being independently driven, can take their own speed, and each pair get the best grip.

Another thing to be noted, where the ground circuit is used, is the increase of traction due to the passage of the current from the wheels into the rails. Exactly what molecular action takes place has not been ascertained; it may be simply heating at the contact surface, but the fact remains that the traction is very largely increased. The magnetic condition of the wheels and tracks also has some function in this increase of traction. The wheels and axles are magnetized by the method of motor construction and mounting, and also by the passage of the current through them; the tracks are likewise magnetized by the current passing through them, and also by the rolling contact of the wheels. Yet, admitting all these aids, the results have been extraordinary.

Sixteen-foot closed cars carrying picked loads of fifty-five to sixty passengers, and having a total weight of 15,000 pounds are operated on the 10 per cent. grade, often with a slippery and slimy rail, and on 27-foot curves, without the use of sand or extra help.

These same grades and curves have been ascended without sand after one of the worst sleet storms which has visited this section for years. Various tests under the most unfavorable conditions have been made, cars often being required to cut their way through clay, snow and ice when the tracks were out of sight. No severer test could have been made, and the power and tractive effort developed have exceeded the most sanguine expectations.

Cars have often been stopped and started on the heaviest grades, and in the sharpest curves. One motor has propelled two cars around sharp curves and up six per cent. grades. One car has pushed another of greater weight around the sharpest curves and up seven and eight per cent. grades both straight and combined.

I have no hesitation in saying that with a clean track, and with proper gearing, these cars could mount a 15 per cent. grade, depending on adhesion alone. During the four months operation, although there have been troubles and changes have been made while the cars were running commercially, no car has been pulled a foot by animal power; if any accident has occured to a motor the car has gone along with one machine, oftentimes with heavy loads and on heavy grades, or in some cases has gone home in company with another car. One-hundred-and-forty men who did not know the difference between a motor and a hand saw, have been broken in to handling these cars; oftentimes with remarkably short training. Up to Saturday, May 12, the number of regular cars on duty had not exceeded twenty. On that day at 4 P. M., the hour when traffic becomes exceptionally heavy, we began putting out ten open cars, starting them from the eastern car house alternating with the closed cars, but finally banking them all up at the Old Reservoir. At 6 P. M. they were started home, and shortly afterwards these ten open cars, headed by a closed car, were all run at full speed close together down the east-bound track of Clay street. At one time fourteen cars were on the line between Clay and Hancock streets and the Old Reservoir, and shortly before

7 o'clock there were about twenty-two cars on the line between Capitol square and the Old Reservoir, and at 7 o'clock thirty cars were on the line, the closed cars being very heavily loaded, many

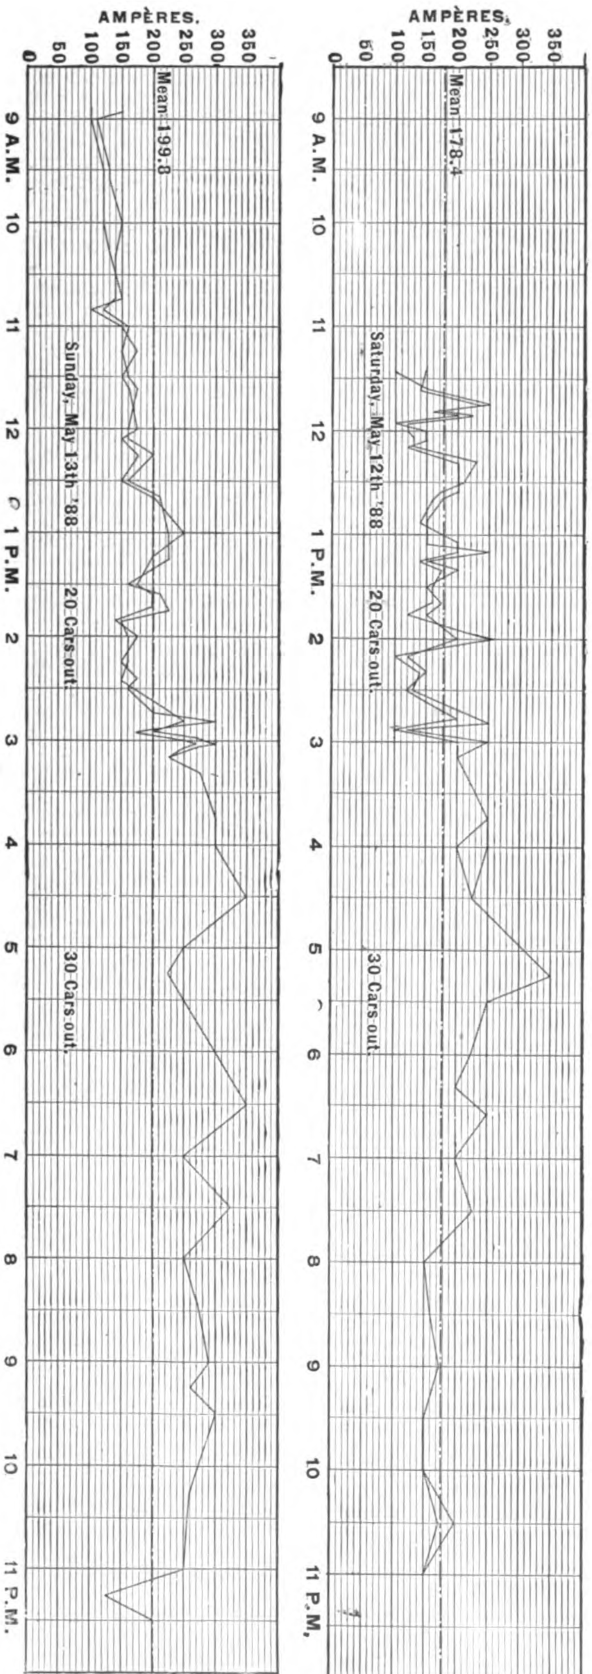

FIG. 3.—Ampere Diagrams, 20 and 30 Cars on Track.

of the cars being run with two minutes interval. The three boilers, whose capacity is 375 h. p., were then supplying three Armington & Sims engines of 125 h. p. capacity, which were driving the six railroad dynamos, and two Westinghouse engines of 110 h. p. capacity, which were driving two alternating current dynamos and exciters with an equivalent load of 1,060 incandescent lamps. The mixture was enriched and the firing of boilers became pretty active, there being in addition to the thirty cars badly banked about 110 h. p. taken for lighting.

The highest reading (Fig 3), however, on the line was less than three-quarters of the normal capacity of the dynamos, which were originally intended only for thirty cars, and the average reading for this number was only a trifle over half the normal capacity. Most effective work was done by the automatic steam regulator as was shown by the steam diagram for the same day.

The ampere readings taken at intervals of ten and fifteen minutes give a load diagram, which is really higher than a continuously recording instrument would show.

The figures which follow, being based upon an actual service increasing from eight to thirty cars, and extending over a period of four months under the most trying circumstances, and at the most critical and care-requiring period of the enterprise's existence, will give street railway men the most careful and liberal estimate of every possible expense attending the operation of the road which is in any way dependent upon its electrical features. The operating expenses are given under two heads; first, the central station operating expenses, and second, the road operating expenses, the two constituting the total cost of motive power. These are given in detail, and they will probably be found to cover every expense, although in some small ways the distribution of these expenses may be found to be changed by several months longer running. The fuel and other incidental expenses of the station are from the engineer's record, and checked by the readings of the electrical instruments.

For thirty cars running on a double track the central station expenses are about as follows:

52 42-100 cwt. coal, at 10 cents	$5.84	
113 70-100 cwt. screenings, at 7 cents	7.96	
5 pints cylinder oil, at 75 cents per gal.	.47	
5 pints dynamo oil, at 30 cents per gal.	.18	
8 pounds waste, at 10 cents	.30	
Water at current rates	3.00	
Fuel, etc.		$17.75
1 day engineer	$3.00	
1 night engineer	2.25	
4 firemen	6.00	
1 cleaner	1.50	
2 dynamo men	3.50	
1 electrician	4.00	
Labor		$20.25
Lighting		.50
Depreciation and repairs on dynamos, 3 per cent.		1.50
Depreciation and repairs on engine and boilers 10 per cent.		4.38
Total central station expenses		$44.38

Or $1.48 per car making 80 miles.

[The central station being operated for twenty-fours for lighting and power purposes, the lighting company has now assumed charge and rents the power to the cars at $1.60 per day.]

In estimating the road expenses more than liberal allowance is made, but in a new enterprise it is safe to err on this side rather than attempt to claim for a system advantages which will not in practice be borne out. The expenses are then as follows:

Oil, grease and waste	$4.50	
Brushes	3.00	
Trolleys	2.00	
Material		$9.50
Three mechanics and one helper for thoroughly overhauling motors once a week, making repairs, adjusting brakes, etc.	7.90	
Four inspectors, two day and two night, for oiling machines and looking after brushes	7.50	
Two night inspectors to thoroughly inspect motors after cars are laid up and see that all bolts, nuts and connections are tight and that everything is in good working order for the morning run	4.00	
One winder and helper for making any repairs which may be necessary and any testing which is required	3.50	
Two linemen	5.00	
Labor		$27.90
Depreciation on car work at 15 per cent.	18.00	
Depreciation on line work at 10 per cent.	4.00	
Depreciation		22.00
Total road operating expenses		$59.40

or $1.98 per car making 80 miles.

The total motive power expenses both in the central station and out on the road would not then exceed $3.46 per car making 80 miles, or 4.32 cents per car mile, and this includes everything except the executive and salary expenses, taxes and insurance, and is less than 40 per cent. of the cost of operation by horses with the same number of cars, and under the same conditions.

But the showing is even better than this, for another fact is to be noticed, and it is an important one from an economical point of view. For example, 20 cars on duty for about 18 hours make a mileage of from 1,500 to 1,800 per day, and if it were not for the

fact that the schedule requires them to operate part of the time on a single track with insufficient turn-outs they could make 1,800 or 1,900 steadily. This, notwithstanding the fact that the speed is limited by municipal regulations. Many of the cars often run 90 to 100 miles. The same mileage and intervals made by 20 electric cars could not, under the circumstances, be made by anything less than 25 horse-cars of the same size, and the electric cars probably carry in the aggregate just as many passengers. It follows that to get the same service with horses not only would the number of cars have to be increased, but likewise the number of horses, conductors and drivers. The same mileage performed by horses without these cars and grades would require a stable equipment of not less than 300 horses.

A good idea of the operation of the system may be obtained from the following weekly table, taken from the records of the railway company up to the present date :

Week ending.	No. of cars put out for regular service.	Average No. of cars out per day.	Miles per week.	Avg. miles per day.	Avg. miles per car per day.	Passengers per week.	Average passengers per day.

With the mileage which is now made, there is an actual saving of about $125 per day in the motive power expenses as against operation by horses. It is hardly necessary to point out that this would pay a good interest on a pretty large investment. The capacity of the road to economically carry passengers has been made so apparent that the old city railway, which was operated by mules and has about 13 miles of track and 50 cars, has been bought up and is to be equipped with motors operated from the same central station. A third line will probably be added, and in the near future every street car, to the number of 100, in Richmond and Manchester will be electrically operated from one station.

From this same station is operated a power and light circuit.

Having thus seen what is possible on a street railway, let us briefly consider the application of electricity on a larger scale.

The failure of the elevated railroads in this city to meet the issue of rapid transit is in no way more forcibly illustrated than by the number of plans which have been brought forward for discussion. No less than 11 have presented themselves, several of which have features in common and claim similar routes; and I will but very briefly review them.

The Beach Pneumatic was merged into the Broadway Underground, and this in turn into the New York Arcade Railway Co., and it is now familiarly known as the Arcade. They propose to run from the Battery, thence to Broadway and Madison square, with four tracks, the two centre being express tracks, with stations one mile apart, and the two outer tracks for way traffic. Thence the route extends to 59th street by Broadway, and to the Harlem river by Madison avenue, with an additional route up the west side of Central park by the Boulevard or some other avenue, and into the annexed districts. Branches are proposed to connect Broadway and Madison avenue on 23d street, and the two branch roads on 42d street.

The Underground Railway Construction Co. has pooled the issues of the New York District, New York Underground and the Metropolitan Junction companies. The route of the first is similar to that of the Arcade, and runs from the Battery to Broadway and Madison square with four tracks; thence up Broadway to 59th street, and up Madison avenue over the Harlem river to some point near Jerome park. Branches are also proposed from river to river on 12th and 23d streets. The New York Underground road propose to run from the City Hall park east to Broadway, through Centre and Mulberry streets to Lafayette place and 4th avenue at Union square. Thence by two lines to the Grand Central, and Broadway and 59th street, up the Boulevard to Kingsbridge, the main line continuing under Madison avenue to the Harlem river and by a loop to Kingsbridge.

The Metropolitan Junction Co. proposes to connect with the two last named in the annexed districts, and then run over the Hudson by a bridge at Washington Heights, connecting with a tunnel through the palisades.

The City Railway Co. proposes to begin at South and Whitehall streets, crossing Broadway below Rector, running between Church street and College place, 6th and 7th avenues to 59th street and the Boulevard. The line would then run up the west side of Central park, crossing the Harlem river above High bridge, terminating in New Rochelle. Branches are proposed for the principal ferries on both rivers, the post office and Grand Central station. The roadway is intended to be 50 feet wide and 12 feet below the street surface; it is to have four tracks, two way and two express. It differs from the other underground railways in that instead of taking the street lines it proposes to purchase the necessary property and erect buildings over the line of the road, which are to be rented for sufficient to pay the bonds of the company. The road thus running through the basements, so to speak, of the buildings, and crossing the streets by tunnels, becomes a covered roadway instead of an open one.

The Terminal Underground Railway Co. proposes a four-track underground railway from the City Hall along the proposed Elm street improvement to the Grand Central depot.

The Metropolitan Transit Company proposes two elevated steel structures, one on Broadway, between Chambers street and Forty-third street, connecting with the Grand Central Depot, and the other on the West Side, following the line of the water front to Gansevoort Market, thence up Tenth avenue and the Boulevard to Kingsbridge.

The plan proposed by Heman Clark is one of the most radical. He proposes a four-track tunnel, beginning near Fleetwood Park, cut in solid rock 150 feet below the surface, coming down about 100 feet west of the line of Broadway to the Astor House, where it would connect with two two-track branches, one going under the North River to Jersey City and Newark, and the other under the East River to Brooklyn and Prospect Park. Passenger stations would be at the foot of shafts, sunk every two miles, and freight stations at intermediate shafts, where freight pockets would be tunneled. Large elevators would be used for handling the passengers and freight.

All of these schemes have their good and bad points which I do not propose to here discuss; but whichever is successful, they hope to use electric motors for propulsion. Now, whatever we may claim for electrical motors, it would be folly to attempt the handling of the traffic of such a road without full knowledge as to the character of the work which has to be performed and a perfectly definite idea of the system of train despatching which will best meet the wants of the public and, at the same time, preserve an effective and economical system of operation. To fully consider this let us briefly review the work which is being done on the elevated railroads, for example on the Third avenue line.

This is eight and a half miles long. Grades vary from eight to one hundred and five feet to the mile. The level stretches amount to about one-third of the whole distance, and this includes the stations. On the seventeen miles of single track there are fifty-two stations. In the busy hours there are no less than sixty-three, four and five-car trains on the tracks. These trains, weighing from eighty to ninety-five tons, make the half trip in forty-two minutes, including stopping at twenty-six stations and discharging and taking on passengers, or at the rate of about ten traffic miles per hour. The work of the engines may be divided into three parts; overcoming the train's inertia, lifting the train on the grades and traction; and the maximum is at least seven times that necessary for traction at mean speed on a level. Three times in every mile this weight of 80 to 95 tons must be started from a dead rest, raised to a speed of twenty or more miles an hour and brought to rest in about eighty seconds. The engines have to be run with 130 pounds boiler pressure, and have a capacity of 185 h. p. Fifty-nine per cent. of the power on a round trip is used in starting, 24 per cent. in lifting, and 17 per cent. in traction, and the average power developed per minute per round trip, including stoppages, is 70.3 h. p.

The traction necessary to handle these trains is obtained by a locomotive weighing 22½ tons, of which only 15 are carried by drivers five feet apart. With an engine and the forward trucks of one car between two girders, we have a weight of nearly 1,500 pounds per running foot. The present weight of engines is not sufficient to properly handle these trains when the tracks are in a slippery condition, and it is not wise to increase it. It is absolutely necessary to keep up the high character of the engineering work of this road, and every consideration of business, prudence and public safety will permit of no laxity in this direction. Yet these locomotives have done wonderful work. Although on duty for twenty hours, with steam admitted to the cylinder for six hours only, with an average horse-power of only 38 per cent. of the maximum, and with all the incidental losses of steam, they develop a horse-power with less than a total expenditure of 6.2 pounds of coal per hour; and the coal expense alone is only about $1.15 per round trip, or 2⅛ cents per train station. The operating expenses are 62 cents per train mile; or, allowing an average of four cars per train, 15½ cents per car mile; and this includes everything.

The percentage of expenses of operation and maintenance for the whole Manhattan system may be roughly expressed as follows:—

Motive power	42.8
Maintenance of cars	5.4
Movement of traffic	38.4
Maintenance of way	8.2
General expenses	7.2
Total	100.0

The coal alone costs over $700,000 per annum, which is more than the wages of the engineers and firemen, but it is only about one-sixth of the total operating expenses. Hence there are other reasons than merely a saving in coal which must be urged in favor of an electric system as against a steam system.

Generally speaking, the real needs of rapid transit are not best subserved by the handling of long trains from a single tractive engine. True, the conditions of service on the elevated railroad, the crowded condition of the track, and the great cost of operating independent steam engines makes it impracticable to work with small train units there. But the fact remains that the effective length of train which can be operated by any system is limited; that this limit has already been reached on the elevated railroad, where only one-sixth of the weight is now effective for traction; and that the smaller the units the less the momentum of the train and the easier it is to quickly and efficiently handle it, and the less will be the liability of, and danger from, any derangement of the brake apparatus. Furthermore, the thrust of the moving weights on the grades, the vibration due to the shifting of the weight along the girders, the tensile, shearing and crushing strains on the structure are all materially increased by the use of a heavy locomotive at the head of a long train.

But since we must endeavor to meet all conditions of engineering, we must try to meet that one which requires the operation of a heavy train by a single motor car. In this case I deem it advisable to make the motor car of about the same size as the cars which form the train, equip both trucks and thus spread the weight used for tractive purposes over a larger distance. We have now partly constructed a 300 h. p. motor equipment of this character.

This car, whose general external dimensions are similar to those of the regular elevated passenger coach, differs in its construction in many important details. The front and rear platforms are inclosed, and about ten feet at each end of the car—that is, the space over the trucks—is partitioned off and reserved for the use of the motor man. The middle space has side entrances, and is fitted for passenger accommodation. At each end of the car the floor framing is raised about twelve inches for a distance of about ten feet from the end, and the car body is carried on two very strong and heavy special iron trucks mounted on forty-two-inch wheels fitted with five-inch steel axles. Each axle has an independent movement and is driven by a tandem motor, centred upon the axle, which bears a part of the weight. The motor is also carried by heavy compression springs hung from the truck, by means of which as much of the weight of the motor as is desired can be thrown onto the boxes. Each motor, which is of about 75 h. p. normal capacity, has two armatures, each of which is connected to a fixed and adjustable gear on the axle, the ratio of the gearing being about 1 to 3. These motors will have one brush on each commutator, and that will be a top brush. Each motor has directly over it, in the engineer's room, trap-doors fitted with heavy glass panels, which allow the machines to be seen at all times, and through which the machines can always be reached. The controlling devices and switches are all duplicates, and the car can be handled from either end. The car and the trucks are completed; the motors are well under way. The car will be capable of exerting a tractive strain of at least 20,000 pounds—more than double that of the present locomotives.

But this is not the ideal method of traction.

By a system of electrical propulsion, the power can be distributed underneath the cars, every car, or every two cars if need be, being a unit; and, although I do not think it advisable, arrangements could be made for propelling a large number of cars under simultaneous control. By distributing the power under the car, the whole weight of the car and passengers can be made effective for traction. This will enable the cars to be started more promptly, brought to speed more quickly, and stopped in shorter intervals, increasing the mean rate of speed for a given maximum, or vice versa, reducing the maximum for a given mean rate. By making cars individual units of locomotion, the intervals between trains may be made one-fourth or one-fifth of the schedule which must exist where four or five-car trains are used. It may be said that this will increase the number of employés that are necessary. This is true; but it will increase the number of passengers who, both day and night, would make use of the system, in such a ratio as would make this increase of expense insignificant.

Let us consider a possible system which would go a long ways towards solving the question of rapid transit. I will briefly point out its features. It would have four tracks extending from the battery up Broadway to twenty-third street; thence diverging in two divisions, each still with four tracks, one along the line of Madison avenue to the Harlem river and terminating near the Jerome park district; the other following Broadway and running up the line of the Boulevard and Tenth or Eleventh avenues. Two tracks would be reserved for express traffic, with stations a mile apart, and two for way traffic, with stations every third of a mile, every third way station corresponding with an express station. The tracks would be arranged in two tiers, the express tracks being the lower. The entire system would be lighted, ventilated and operated by electricity, to be supplied from four stations on the water front, one at the Battery, one at East Twenty-third street, one at Madison avenue crossing of the Harlem river, and one on West One Hundred and Twenty-fifth street; the stations to be operated by compound condensing engines in three units connecting directly to large, slow moving multipolar dynamos, two engines being of sufficient capacity to handle the demand made upon any station; trains to be operated with one or at most two car units; motors to be on the trucks of one car, centred on the axle and with one reduction of gearing; express speed to be thirty miles an hour, and way trains to make twelve traffic miles per hour; the current to be delivered to the cars by an overhead system with underneath contact, the contact wheel to be carried on the car, supported over the centre of the truck and trending a little abaft it. Freight pockets at the level of the way track could be run under the cross streets at express stations. Track to follow a line of grade of not more than 25 per cent.; access to stations to be by stairways, and where there is any material difference between the street level and the track, by hydraulic elevators, operated from constant pressure tanks kept supplied automatically by motors. Freight trains to be run on way tracks.

Supplementing this system should be a line of surface cars, likewise operated by electricity from the same general source. In the heart of the city these can be operated from a conduit, or by the storage battery, and in all the suburban extensions by the overhead line system.

The objection of loss in transmission and recovery has been raised as against an electric system, and also the question of braking. These are easily met.

We have systems of electrical braking a train by the use of its motors, which consists in converting them into dynamos, deriving their driving power from the train, and using up its energy by converting it into electrical energy, which can be used in a variety of ways. In a storage battery system the energy of the car can be made to partially recharge the batteries on a down grade and in stopping. In a direct supply multiple arc system, operating a large number of cars, this power of at will being able to convert the energy of a moving train into electrical energy delivered to the line by the same apparatus which controls the speed and power of the train is of exceptionable importance. In a double track system, the energy given to one track may be communicated to the other just as efficiently as along itself. In fact, in the entire electrical system, every part is mutually connected, and there is a bond of union between the different trains far more perfect and effective than any mechanical connection could be. The up-grades on one track being equal to the down-grades of the other, it is evident that the total up-grade of a system is equalized by the down-grade thereof. If, then, energy is expended in getting under way and climbing up-grades, and a large proportion of this can be recovered in stopping and in running down-grade, it is evident that the total initial energy required would be that necessary to move the trains continuously on level grades, with a percentage for loss in conversion and reconversion added. The more train units which are operated, and the more frequent the stoppages, the more marked is this advantage in an electric system.

I some time since made a number of determinations of a system of the equipment capacity of the Third avenue elevated, in which I found that about 40 per cent. of the power could be saved by this system of braking, where every motor coming to a station or running of a down-grade is made a generator which is helping to supply the current needed to operate the remaining trains.

Instead of the current being all supplied by a main generating station at one or two points, it would be supplied from nearly as many moving stations along the line as there would be trains slowing down or running on a down-grade. In fact, the loss of the two conversions and one transmission would be more than counter-balanced, and consequently the original horse-power at the central station would be no more than the aggregate net horse-power now developed on the entire line, and this is only about 38 per cent. of the total capacity of the engines. With any given potential and losses on the line, the main conductor would be very much smaller. Not only on the line, but at the central station would a saving be effected; for in a system of the capacity of that which we are considering this saving on lots, buildings, boilers, engines, dynamos and fittings would be not less than $400,000, and there would be about 40 per cent. saving in the coal, labor, depreciation and incidental expenses of the central station.

Another method of using the motors for braking purposes is to break the connection from the line and reverse the machine through a local circuit on the train, varying either the local circuit or the circuits of the machine. While in this position of braking, if the local circuit is opened and the line connection made, the machine would be instantly reversed.

Elaborate experiments were made by me nearly two years ago on the Thirty-fourth street branch of the New York Elevated Railroad, in which these questions of gearing, of mounting the motors on trucks under the car, and handling the car without shoe-brakes were very thoroughly studied. There, this method of braking was shown to be under the most perfect control. When desired, the braking could be made so sudden as to cause the wheels to have a continuous skidding rotation, not such a skidding as is caused when an air brake is put on too sharply, but a rotating slip which is just enough to relieve the armature when the strain on it reaches the point determined by the coefficient of adhesion on the rails.

This is the ideal method of braking, because fixed skidding and flat wheels are an impossibility, and the wheels will turn until the train comes to a dead stop, although, where the braking power is put on too suddenly and exceeds the grip of the wheels, they will relieve themselves by slipping just enough to keep the braking at the maximum limit. A train so governed can be made to creep down the maximum grade of a road at a snail's pace, and in an emergency such a car, running 21 miles an hour on a down grade, has been stopped and reversed within 90 feet.

When an electric motor is reversed its action is cumulative, for so long as its motion continues in its normal direction, it tends to augment the current which flows through it with any given setting of the switch, and thus very much increases the effort to stop itself; and the higher the velocity at which the armature is traveling, the greater this effort. In fact, it would be practically impossible with a properly constructed railroad motor to prevent its reversing when the switch is thrown over far enough. This is another point in which an electric motor has a great advantage over a steam engine.

So it would seem that electricity has practical advantages over steam for this character of traffic, and there are considerations other than purely engineering ones. The use of electricity instead of steam would do much towards making a road of this character popular. We would have express and way trains, starting and stopping smoothly and quickly, moving at a high rate of speed and running at short intervals. Dust, smoke, cinders, oil and drippings would disappear; the air would be purer and cleaner. The trains would be safer and under more perfect control; motive power would cost less; depreciation on the track structure would be much less; the carrying capacity would be increased; cars would be brilliantly lighted; comfortably heated; in short, everything which would make rapid transit safe, pleasant and effective is possible by a properly developed system of electric traction.

One of the most important sources of revenue from such a system would be the sale of power for stationary purposes. Already we are operating no less than 130 different industries by electric motors, and the receipts vary from $60 to $150 per horse-power. The extent of the application of electricity with any such general source of supply can hardly be conceived. Its profits would be far more than enough to pay the total cost of motive power.

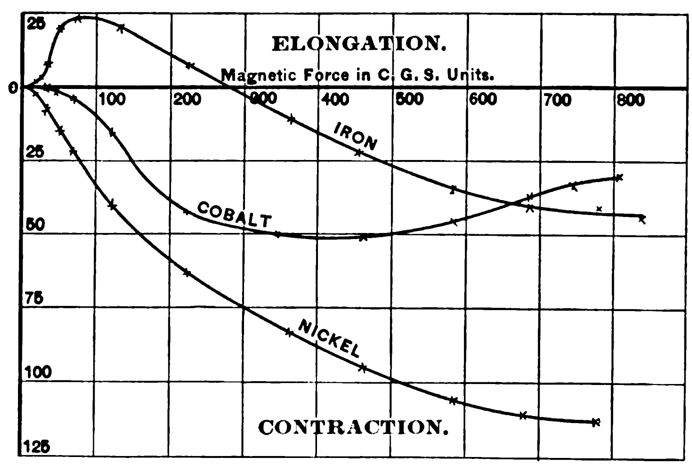
But we must not shut our eyes to the work which has got to be done. We must not exaggerate the advantages of electricity; we must not belittle the position of a system which has been developed by the ablest engineers for the last forty years. All their experience, all their study, all their victories form a magnificent groundwork for us to build upon, and will render the final victory of electricity more easy and certain if we build wisely and take to heart all the lessons which their years of experience teach us. In a small fraction of the forty years which have marked the development of steam engineering, electric engines will rival in mechanical perfection, in construction and performance, the best locomotives. Even to-day, weight for weight, and duty for duty, the electric motor is already rivaling and outstripping its predecessor. For the present, and for a long time to come, it is probable that for trunk line work, and for the original source of our power in an electrical system, we will be dependent upon the steam engine; but we all hope and expect that the future will bring us some other effective means of converting the energy of coal into electrical energy, and that by some direct method which will not require the intervention of a steam engine and dynamo. It is not too much to hope for, and already experiments have been made which foreshadow this great result. The success of this discovery would produce such a revolution in the use and distribution of power as to exceed our most sanguine expectations.

.... I CERTAINLY think there is a field for alternating motors, and there is undoubtedly an opportunity for obtaining motors which possess even some advantages over the continuous current motors.—*Elihu Thomson.*

ABSTRACTS AND EXTRACTS.

THE ELONGATION AND CONTRACTION OF METALS IN MAGNETIC FIELDS.

IT has long been known that a bar of iron when magnetized by a surrounding solenoid alters its length, and with the weak magnetizing forces which were originally employed in these experiments, the alteration was invariably an increase in length. One of the earliest experimenters, and probably the original discoverer of this behavior of iron when magnetized, was Joule; but he invariably found that the length increases with the magnetizing force. In his experiments, however, the magnetizing force did not exceed 87 C. G. S. units, and an ingenious theory was propounded to show that elongation must take place when a bar of iron is magnetized. It was believed that the molecules as they rotate under the influence of the lines of force, and become more or less parallel, naturally require more room in the direction of the length of the rod, and therefore cause the latter to extend with a corresponding decrease of diameter. This simple explanation was refuted by the experiments of Mr. Shelford Bidwell, which he made some years ago, and in a paper communicated by him to the Royal Society in 1885, he showed that the elongation does not remain unchanged at its maximum when the magnetizing force exceeds that which is sufficient to produce so-called saturation; but, on the contrary that with increasing magnetizing forces beyond this limit the elongation becomes less until the rod, after returning to its original length, ultimately becomes actually shorter than it was in the unmagnetized condition. Mr. Shelford Bidwell has, however, recently contributed to the Royal Society, another paper on the same subject, and in this he points out that his original investigations might be open to the following objections: (1) The field due to the magnetizing solenoid was not



quite uniform; (2) the effect of the ends of the rods was uncertain, and might have played some material part in the production of the phenomena in question; (3) all the rods used in the experiments retained a certain amount of permanent magnetism. To meet these objections he has carried out a further series of experiments by using rings instead of rods of iron, and observing the changes of diameter. The rings were also demagnetized before every observation, and the battery employed was much stronger than that used in the first experiments, so as to produce very great magnetizing forces. He found that in their general character the phenomena of elongation and contraction were the same with rings and with straight bars, thus proving that the effect of magnetization was independent of the form of the iron, and as it was much easier to obtain intense fields with straight than with circular solenoids, the author made some further experiments with straight rods. These experiments embraced iron, cobalt, nickel, manganese steel, and bismuth, and the highest magnetizing force reached was 840 C. G. S. units. We are able, by the courtesy of Mr. Shelford Bidwell, to publish herewith a diagram showing the behavior of iron, cobalt, and nickel in magnetic fields of varying intensity. The strength of field is plotted on the horizontal, and the change of length in ten millionths of the original length of the rod is plotted on the vertical, the elongations being plotted above, and contractions below, the axis. The line of bismuth, which metal was tested in fields varying from 500 to 840 units, almost coincides with the axis, and manganese steel was also found to be almost unaffected, the elongation in a field of 850 units being only about one-fifty millionth of the length. That the change of length in the other metals which are sensibly affected by magnetization cannot be due to the mechanical stress produced by magnetic attraction between

the ends of the bar, is shown by the author in the case of iron where mechanical stress does not account for more than one-fifths part of the observed magnetic contraction. It should also be remembered that up to a magnetizing force of 280 units, iron elongates, and, therefore, the mechanical stress in iron opposes magnetic extension.—*Industries.*

EFFECTS OF DIFFERENT POSITIVE METALS, ETC., UPON THE CHANGES OF POTENTIAL OF VOLTAIC COUPLES.[1]

BY DR. G. GORE, F.R.S.

In this research numerous measurements were made, and are given in a series of tables, of the effects upon the minimum point of change of potential of a voltaic couple in distilled water (Roy. Soc. Proc., June 14, 1888), and upon the changes of electromotive force attending variations of strength of its exciting liquid (*ibid*), obtained by varying the kind of positive and of negative metal of the couple, and by employing different galvanometers. The measurements were made by the method of balance through a galvanometer, with the aid of a suitable thermo-electric pile (Birmingham Philos. Soc. Proc., vol. iv., p. 130. *The Electrician*, 1884, vol. xi, p. 414.) The kinds of galvanometer employed were an ordinary astatic one of 100 ohms resistance and a Thomson's reflecting one of 3040 ohms resistance.

The following were the proportions of hydrochloric acid (hcl) required to change the potential of different couples in water:—

TABLE I.—HYDROCHLORIC ACID,

Couples.	Astatic galvanometer.					Reflecting galvanometer.				
Zn + Pt	Between	1 in	9,300,000	and	9,888,185.	Between	1 in	15,500.000	and	23,250,000
Cd + Pt	"	1 "	574,000	"	637.000.	"	1 "	1,162,500	"	1,550,000
Mg + Pt	"	1 "	516,666	"	574,000.	"	1 "	775,000	"	930,000
Al + Pt	"	1 "	12,109	"	15,000.	"	1 "	42,568	"	46,500

With iodine and the astatic galvanometer the following proportions were required :—

TABLE II.—IODINE.

Zn + Pt.	Between	1 in	3,100,000	and	3,521,970
Mg + Pt.	"	1 "	377,711	"	643,153
Cd + Pt.	"	1 "	200,431	"	224,637

With bromine and the astatic galvanometer:—

TABLE III.—BROMINE.

Mg + Pt.	Between	1 in	310,000.000	and	344,444,444
Zn + Pt.	"	1 "	77,500,000	"	84,545,000
Cd + Pt.	"	1 "	3,470,112	"	3,875,000

The magnitudes of the minimum proportions of bromine required to change the potentials of the three couples in water, varied directly as the atomic weights of the three positive metals.

With chlorine the following were the minimum proportions required:—

TABLE IV.—CHLORINE.

With the reflecting galvanometer.

Mg + Pt. Between 1 in 27,062,000,000 and 32,291,000,000

With the astatic galvanometer.

Mg + Pt.	Between	1 in	17,000,000,000	and	17,612,000,000
Zn + Pt	"	1 "	1,264,000,000	"	1,300.000,000
Zn + Au	"	1 "	518,587,360	"	550,513,022
Cd + Pt	"	1 "	8,733,585	"	9,270.833
Zn + Cd	"	1 "	55,436	"	76,467

In the case of chlorine, as well as that of bromine, the magnitudes of the minimum proportions of substance required to change the potential of magnesium-platinum, zinc-platinum, and cadmium-platinum varied directly as the atomic weights of the positive metals.

The examples contained in the paper show that the proportion of the same exciting liquid necessary to disturb the potential of a voltaic couple in water varied with each different positive or negative metal, and that the more positive, or more easily corroded the positive metal, or the more negative and less easily corroded the negative one; the smaller usually was the minimum proportion of dissolved substance necessary to change the potential.

By plotting the results in all cases, it was found that the order of change of potential caused by uniform change of strength of liquid, varied with each positive metal.

The results also show that the degree of sensitiveness of the arrangement for detecting the minimum point of change of potential depends largely upon the kind of galvanometer employed.

As a more sensitive galvanometer enables us to detect a change of potential caused by a much smaller proportion of material, and as the proportion of substance capable of detection is smaller the greater the free chemical of each of the uniting bodies (Roy. Soc. Proc., June 14, 1888), it is probable that the electromotive force really begins to change with the very smallest addition of the substance, and might be detected if our means of detection were sufficiently sensitive, or the free chemical energy of the uniting bodies was sufficiently strong.

1. Read before the Royal Society, June 21, 1888. Abstract.

POINTERS.

.... I THINK we are well within the mark when we say that we can maintain accumulators for 12½ per cent.—*R. E. Crompton.*

.... THERE is no doubt that iron in the armature is the essential feature of a good alternating dynamo.—*Professor George Forbes.*

.... IN any properly engineered railway plant, the electrical pressure should not vary 10 per cent. in any part of the circuit. —*F. J. Sprague.*

.... THE regulation series system in its different classes, single and multiple series, has been the ignis-fatuus of electricians in incandescent lighting.—*F. J. Sprague.*

.... IT is found most positively that the return of the Westinghouse transformers is more than 600 kilo-watts in the lamp for the indicated horse-power.—*Professor George Forbes.*

.... THE Americans like mud...... In some towns arc lights are hoisted on poles some hundreds of feet high; this is no doubt a frantic effort to get clear of the mud.—*Swinburne and Sellon.*

... THERE is far too general an idea that electrical engineering is a genteel profession, and that a man can get on well in it without soiling his hands. This is a mistake.—*Electrical Engineer* (London).

.... THAT is, 80 per cent. of the indicated horse-power in the cylinder of the steam engine in effective horse-power at the terminals of the lamps. Never was such a monstrous statement made.—*R. E. Crompton.*

.... A YELLOW incandescent wire flickering in a finger-glass at the end of a gibbet—hardly equal to those sold at a shilling a box, known as Price's patent night lights.—*Councillor Crowther Davis, of Leamington, England.*

.... WE find actually that aluminum is really capable of giving an electromotive force less than zinc ; so that it would seem as though by the proper use of zinc in some way or other we might separate aluminum.—*Elihu Thomson.*

.... WHEREVER overhead wiring can be used I have no doubt that distribution by means of alternating current transformers is a very good system to use, and probably is considerably cheaper than that by batteries.—*R. E. Crompton.*

.... THE scientific method of investigating historical events has shown us how false, how childish, is the "great man" theory of history...... But if the great man theory of history is fallacious, so is the great man theory of inventions.—*Silvanus P. Thompson.*

.... IN the few months I have been studying the alternating system in America, I have gained more practical information than I could have obtained from reading the papers of all the authors who have written in this country on the subject.—*Professor George Forbes.*

.... Do not be fooled because a two-horse motor can do five horse-power. It is a beautiful thing to show a customer, but when you put a meter on the circuit you will feel sad when you find the small amount of money you are getting for the power used.—*Frank J. Sprague.*

.... THE chief difference between American and English practice is to be found outside the station. The American machinery is all very well made in the first place, and it is well managed and well looked after in the station, but the outside installation work is very terrible.—*Swinburne and Sellon.*

.... THE man who knows a lot about curves and formulæ and book learning generally, is not worth a d—ump if he cannot handle a hammer, screwdriver or soldering-iron, and is afraid to tackle any difficulty out of which he cannot see his way with mathematical accuracy.—*Electrical Engineer* (London).

.... THOUGH there is nothing that requires such accuracy and rapid handling as a great gun in a seaway, there is no other engine capable of such accurate and rapid work as an electric motor ; its advantages over steam, hydraulic and pneumatic engines are so marked that it would be idle to compare them.—*Lieutenant Bradley A. Fiske.*

.... As to the opinion of certain English scientists on the question of saving in the first cost of the three-wire system over the two wire, it has been frequently stated that the maximum saving of the three-wire system is 25 per cent. and that any further saving in copper beyond that was altogether chimerical. The fact is that the saving is 66 per cent.—*H. Ward Leonard.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Underground Litigation.—End of the Cable War.—The Phonograph and the Graphophone make Peace.—Rumored Disaffection among the Operators.—A Lamp Trimmer Killed by the Current.—An Aerial Cable on Fire.—Amateur Telephones Suppressed by Law.

THE subway litigation promises to be a bonanza for the lawyers, as different suits are now springing up which promise to be both interesting and expensive. Commissioner Gibbens is fairly on the warpath, and has made a pilgrimage to the state capitol with a gripsack full of affidavits, and other documents, as ammunition with which to undertake the total demolition of the United States Illuminating Co. The examination before Justice Gorman of the Essex Market Police Court, on July 19th, was upon the complaint of expert Wheeler in behalf of the board, in which the charge is made that the wires of the U. S. Illuminating Co., not being properly insulated, and traversed by a deadly current, are a menace to human life. The defense was, as has already been intimated, that the subways provided under direction of the board are not suitable for the reception of electric light wires

The settlement of the cable war, which has continued for about two years, will no doubt put an end to struggles of that character in ocean telegraphy for some time to come. The low rate has prevailed long enough to decide that cheap cabling is not a financial success. The new rate of 25 cents per word, which is to go into effect August 1, will be continued if it proves more satisfactory to the companies than a higher rate.

The consolidation of the rival interests of the phonograph and graphophone appear to have been finally effected, and Mr. Jesse H. Lippincott, of New York and Pittsburgh, has secured control of the business management of the enterprise, which is expected to be of great importance.

The daily papers have given considerable space to speculation on the probability of another strike among the operators of the Western Union Telegraph Co. It had no other foundation than the fact that the officers of the Brotherhood were showing a little more activity than usual in securing recruits for their organization. They hope to make it strong enough to secure a hearing for their case, whenever they choose to present it. As this necessarily involves recognition of the order, it seems doubtful if it can ever be obtained under the present management, without another bitter struggle for the supremacy, and neither side is at all anxious for a third trial of strength. That will doubtless be left for another generation, unless it should be considered expedient to draw the telegraphers into a fight started by other parties; which hardly seems probable.

William Maier, a lamp trimmer, employed by the Adams Express Co. at 59 Broadway, was found dead upon the floor between two dynamos on the afternoon of July 17th. It was not at first supposed that he had been killed by the electric current, but an autopsy held on the following day proved that such was the case. He left a wife and eight children, one of whom stated that he was troubled with an affection of the heart.

During the heavy shower Thursday night, July 19th, an aerial cable under the elevated railroad at Sixth avenue and Twenty-second street was discovered to be on fire, the flames following the insulation for several feet. At times the flames were extinguished by the rain, and then broke out afresh. No damage was done to anything else.

Some time ago William T. Kitsell had made a telephone receiver and transmitter upon the Bell pattern which he placed in the Hotel Madison for his own use. The American Bell Telephone Co. brought suit against him last summer for infringement, and an injunction with accounting. Application was also made for the removal and destruction of the instruments. The case was heard in equity, Mr. Kitsell confessing the facts. Judge Wallace has granted the perpetual injunction applied for, and the demand for an accounting. He declined, however, to grant permission to remove and destroy the instruments, although he stated he had no doubt of the power of the court to enforce its decree if necessary. In English practice he says such a course is not uncommon.

Lineman George Reid, of the police department, has been presented with a silver medal and $20 cash by the New York Life Saving Benevolent Society, for his courageous action in saving John Reynolds from drowning. The lad fell overboard at the Battery on June 9th.

. . . IN working expenses I think there is little to choose between transformers and secondary batteries...... As to reliability also, I think there is little difference between the two systems. Dynamos may break down in either case, and the remedy for that is to have a spare reserve ready. Too much has been made of the reliability of the accumulator.—*W. B. Esson.*

PHILADELPHIA.

Constant Tearing up of Streets for Laying Numerous Electric Conduits.—Necessity of Single Large Conduit in Principal Streets.—The Keystone Light and Power Co. Seeking to Enforce its Right of Way against the City Government.—The Western Union Co. Closing up a Baltimore and Ohio Office.—The Suit of the City against the Baltimore and Ohio Telegraph Co.

MARKET street, east of Ninth, is constantly being torn up, and Philadelphia will never have well-paved streets so long as the present system of separate conduits, instead of one large subway, is adhered to. The Belgian block pavement on Market street was laid down in 1873 at a cost of $250,000, a special tax being levied for the purpose, and it is now fast becoming worthless. Within twelve years from the time the blocks were put down the crown of the street was broken thirteen times along a considerable portion of its length, and in the past three years no one can say how often the performance has been repeated. As a consequence the street is now in a wretched condition, and every year it becomes worse under the repeated tearings up.

The effect of the continual tearing up of the street is seen in its appearance and condition now while the Edison company is at work putting down its pipes. The pavement is uneven, rough to drive over, and after each break the crown of the street is worse than before.

It is clear that the city can have no decent pavements when they are torn up every few months. With asphalt the results would be worse than with Belgian blocks. The only remedy seems to be in the construction of a subway in which the various conduits and pipes can be grouped, and which shall be big enough for future extensions.

There are ten underground pipes and conduits in Market street; which is 62 feet wide, in addition to a large main sewer.

The pipes and conduits are:—1, 10-inch gas pipe; 2, 6-inch water pipe; 3, American Telephone and Telegraph Company's conduit, 15x13 inches; 4, 20-inch water main; 5, National Electric underground conduit, 2 feet in diameter—tubes laid in concrete, 6, Traction company conduit; 7, Traction company conduit; 8, sewer, 4 feet inner diameter; 9, Edison company's pipes, 18 inches square; 10, 6-inch water-pipe; 11, 4-inch gas-pipe.

The depth below the surface of these underground works varies considerably. The bottom of the sewer is nine feet down. The gas and water pipes are from three to four feet and six inches below the surface. The depth of the American Telephone and Telegraph, the National Electric and the Edison companies' pipes is only two feet, and of the Traction company's conduit three feet and six inches. The water main is four feet and a half down. It will be noticed that all these pipes and conduits pretty well fill the street, but the prospects are that there will be additions to them soon. The Keystone Light and Power Co. wants to put down its wires, and so do the Western Union and Bell Telephone companies. Then there is the project, still in air, of the Market Street Underground Railroad Co., which would occupy 26 feet in the centre of the street, and in the remote future it is possible that the city may want to put down conduits for its electrical system. Director Wagner wants to substitute larger gas mains for those now used; and new schemes to make use of pneumatic tubes are constantly coming up.

The Keystone Light and Power Co. filed a bill in equity recently against the City of Philadelphia in Common Pleas Court No. 1. The bill asks for an injunction against mayor Fitler and the officers of the city to restrain them from interfering with the contemplated laying of electric wire conduits on Sansom street, west of Ninth. The bill avers that by virtue of the act of Assembly of April 29, 1874, they have a right to lay the conduits after obtaining the approval of the board of highway supervisors.

On August 5, 1886, the bill claims, an ordinance was approved by councils granting the company privileges to run on certain streets, including Sansom, from Sixth to the Schuylkill. On April 21, 1887, the board of highway supervisors, through secretary Coppuck, sent in a communication to councils, saying they had examined the application of the Keystone company and had amended the route, and requesting councils to refer it to the electrical committee. Among other amendments suggested was to lay the conduits on the north side of Sansom street, from Ninth to Twenty-fourth. Councils referred the amended bill to the electrical committee, which on June 2, 1887, returned it with a favorable recommendation.

On June 16, 1887, the bill was taken up in its order, when, upon motion of select councilman Graham, chairman of the electrical committee, it was again referred to the committee, where it was permitted to die. On the first Monday of April of this year councils' term expired without further action in the matter.

Last month the company notified director Wagner that they intended laying their conduits on Sansom street, under the act of 1874, and made formal application for a permit. Director Wagner answered that as councils had failed to pass the ordinance he could not grant the permit. A letter was then sent to mayor Fitler, notifying him of the company's intention to lay their conduits without councils' permission, and stating that by their

"letters patent" they had a right to lay them after obtaining the approval of the board of highway supervisors.

The mayor last Friday answered through his secretary that the permit would not be granted, and that should an attempt be made to tear up the streets the work would be promptly stopped. It is for this reason the injunction is asked, the bill stating that the officers of the company fear interference in the exercise of their franchise by the police of Philadelphia.

The action of the Western Union Telegraph Co. in removing the wires and instruments from the office of the Baltimore and Ohio Railroad and Telegraph Co.'s office at Ninth and Chestnut streets is a reminder that Philadelphia is now almost entirely dependent for telegraphic service upon Jay Gould's great monopoly. Other offices of the Baltimore and Ohio company have been gradually closed, and practically all the business of the city is now done over Western Union wires. The only comfort to be extracted from the situation is that these actions of the Western Union all go to add testimony in favor of the city in its suit against the Baltimore and Ohio Telegraph Co.

It will be remembered that when the announcement of the absorption of its rival by the Western Union was made last December, a resolution, offered by John Fow, was immediately passed by city councils instructing the city solicitor to take steps to forfeit the bond of $50,000 filed by the Baltimore and Ohio Telegraph Co., because of its violation of the ordinance of March 21, 1883, under which it was granted permission to enter the city. The ordinance, which was very explicit, said:—

"The said Baltimore and Ohio Telegraph Co. shall give a good and sufficient bond in the sum of $50,000, to be approved by the city solicitor, with the condition that it will not consolidate with any other telegraph company owning a competing line, or acquire by purchase or otherwise any such competing line of telegraph in the State of Pennsylvania or any other state. Provided, that in case of such consolidation, merger or sale of the privileges herein granted to said company, the poles and wires and fixtures erected shall become the property of the City of Philadelphia and the said bond shall be forfeited."

The statement of the city's case, as prepared by assistant city solicitor Walton, who was given charge of the matter, is very simple. It says:—

The plaintiff claims that the defendants have violated the conditions of the said bond in this that the Baltimore and Ohio Telegraph Co. has consolidated with another telegraph company or companies owning a competing line, and has acquired by purchase or otherwise, such competing line of telegraph in the State of Pennsylvania or other state, whereby the amount of said bond has, according to the terms and conditions thereof, become due and payable.

This is followed by an affidavit by mayor Fitler, in which he says that the statement is true to the best of his knowledge, information and belief, by a copy of the telegraph company's bond, which is signed by Robert Garrett, first vice-president of the Baltimore and Ohio Railroad Co., and by the resolution passed by city councils in December.

The affidavit of defense sworn to by President David H. Bates, of the Baltimore and Ohio Telegraph Co., in New York, on February 6, is even more simple than the city's statement. It consists of the declaration that the company "has not consolidated with any other telegraph company owning a competing line, or acquired, by purchase or otherwise, any such competing line of telegraph in the State of Pennsylvania or any other state, and further saith not."

The issue is thus plainly made between the city and the company, and the necessity of furnishing proof to show consolidation of the two companies is thrown upon the city. The case has not yet been given a place upon the court list, but is expected to come up for trial in the fall. Evidence will then be offered to show that there has been such a consolidation as was provided for in the ordinance of 1883, and it is possible that some of the inside history of the deal may be brought out. Notwithstanding the affidavit of president Bates, the *prima facie* evidence all goes to show that there has been a consolidation, merger or sale, the forfeit for which is $50,000.

PHILADELPHIA, July 17, 1888.

.... I REMEMBER hearing Dr. Werner Siemens say with his own lips that it was hopeless to expect to make a dynamo with a higher efficiency than 50 per cent. He lived to see himself mistaken.—*Marmaduke M. M. Slattery.*

.... "IF I were asked for my opinion, I should strongly recommend that the adoption of the electric light in theatres should be made compulsory by act of parliament. It always seems ridiculous to me that while the outcry of exits is chronic, no one thinks of striking at the root of the evil, which is the use of gas behind the stage, where all the materials are of the most inflammable nature. Very little danger can come of using gas in the auditorium, whereas, on the stage, it is a never-ending source of danger."—*W. S. Gilbert.*

BOSTON.

Visit of General Greeley, Chief-Signal Officer in Boston; his Views of the Service.—A Reported Consolidation of Graphophone and Phonograph Interests.—An Extra Dividend by the American Bell Telephone Co.—Output of Telephones.—The Boston Common Council wants to Regulate Telephone Charges.—Electric Light at Quincy.—Electric Light wanted at Sullivan Harbor, Me.—Photographs of Lightning Flashes.—The New England Electric Exchange.—The Police-Signal System in Boston.

THE Boston signal station was inspected by General A. W. Greeley the first of the month. He is east to witness the laying of the new Vineyard Sound cable. He expressed himself satisfied with the workings of the Boston station. The late night maps, to be distributed among all the towns and cities in New England that can be reached before 11 o'clock on the following morning, are now issued. The signal service in general, General Greeley said, was improving in efficiency, but he felt it was time the department was reorganized. There are a good many incompetent men on the stations and all of the men ought to be examined. In order to get the service under the control of a bureau of agriculture, it was intended to make room for favorites and catch the farmers. It got through Congress this year by the member, who introduced it, declaring on the floor of the House that it was General Greeley's bill, which, of course, it was not. It failed in the Senate, and now the recommendation of the chief-signal officer that all the clerks in Washington should be put on the civil list, has been embodied in a bill which is likely to pass.

It is reported here that a consolidation has been effected between the Bell Graphophone Co. and the Edison Phonograph Co. Certain parties are endeavoring to form a local company to exploit the matter here.

The American Bell Telephone Co. have delighted their stockholders, by declaring an extra dividend of $6 per share for the current quarter. Subscriptions for the bonds of the American Telephone and Telegraph Co. come to hand quite favorably, it is understood; there is nothing to hinder the parent company from taking a considerable block themselves if they so choose.

The statement of the output of telephones by the American Bell company of the month ended June 20, and the first six months of the current fiscal year, is as follows:—

May	1888.	1887.	Increase.
Gross output	6,636	6,971	*335
Instruments returned	1,921	1,598	323
Net output	4,715	5,373	*658
Dec. 21 to June 20—			
Gross output	29,261	28,663	898
Instruments returned	10,876	11,114	*238
Ne. output	18,685	17,549	1,136

*Decrease.

At a meeting of the Boston common council, on the 14th inst., an order was offered, providing for the appointment of a committee to consist of five on the part of the council, with such of the board of aldermen as may join, to investigate the subject of telephone charges. The chair appointed Messrs. Hoar, Brooks, McLaughlin, Chamberlain and Dolan.

From information furnished by a prominent city official, it appears there has been considerable discussion at the City Hall relative to telephone charges to the city. The gentlemen referred to remarked that the telephone company had asked for and received many privileges such as conduit and overhead rights of way, etc., for which they had paid nothing, and as it was generally understood that other city governments received large concessions and rebates from the local telephone companies, the city of Boston officials thought that their telephone rates should also be modified.

The Electric Light and Power Co., of Quincy, have had their annual meeting and elected the following named officers: Directors, John Q. Adams, W. G. A. A. Pattee, John R. Graham, John Cashman, James H. Stetson, William B. White, W. A. Stiles; clerk, Walter M. Packard; treasurer, Horace F. Spear. The company will probably begin to light the streets of the town in a week.

The Sullivan Harbor Land Co., located on the main land of Maine, in the rear of Mt. Desert, is advertising for proposals for an electric light system for its property. Both arc and incandescent lamps will be required, and it is proposed to utilize the tidal currents, which run for four hours either way on each tide through a narrow gorge between Fall's Point, Sullivan and Hancock Neck, within 1,500 feet of the village street. Its tide waters fill an immense arm of the sea, which runs up for three or four miles behind the village, and thousands of horse-power go to waste, which it is now proposed to use, and by means of dynamos, run by water wheels and auxiliary storage batteries, light not only Sullivan Harbor, but Hancock Point, Mt. Desert Ferry and Sorrento at one-third the cost of coal.

Several very fine photographs of the lightning on its way to earth were made during the recent storms in this vicinity, and are on sale at several places. In no instance is the jagged, saw-tooth appearance shown, but the peculiar rounded serpentine wriggle is shown in all of them.

The quarterly meeting of the New England Electric Exchange was held on the afternoon of the 9th inst., at the rooms of the Boston Electric Club on Boylston street. President P. H. Alexander spoke of the interest in the exchange and the value of its work, and expressed surprise that only 25 men have applied for licenses, whereas, under the decision of the insurance companies, 600 men must obtain licenses before Oct. 1, if they desire to continue their work. Some changes were made in the plan for issuing licenses. George F. Curtiss of the Thomson-Houston Electric Co. read a paper upon "Lightning Arresters."

Orders were read at roll-call at the several police stations on the evening of the 13th inst., announcing the organization of the police-signal system. The patrol wagons and signals have been in use for some time, but the service of the men is now systematized The order provides for a director of signal service, who has charge of the apparatus of the signals and the patrol wagons. His office is at police headquarters. The patrol wagons are provided with two drivers, one for day and one for night work. With them two patrolmen are to be on duty at all times, to go with the wagon, and be under command of the driver. The wagons are to be run to fires in their districts. Lieutenant H. O. Goodwin, of Division 6, has been assigned to special duty as director of signal service.

Sergeant Charles W. Bower, who has been in charge of the street railway squad, is promoted to the rank of inspector, and appointed inspector of street railway service.

BOSTON, July 16th, 1888.

CHICAGO.

Plans for a Great Underground Electric Railway System.—The Chicago Electric Club; Annual Election; Its Year's Work; Prospects for Next Year.—The City's Arc-Light Plant.—A Batch of Electric Light Franchises Granted by City Council.—The Council and the Chicago Telephone Co.—Death of Alderman Thos. C. Clarke.—A New Focusing Arc Lamp by Mr. E. O. Warner.—Pacific Ocean Cable Scheme.—Suit Against the Chicago Arc Light and Power Co.—The Electric Light Station at Port Huron Burned. —Mr. D. H. Lauderback Resigns the Managership of the Chicago Edison Co.—The Van Depoele Company.—The Chicago Insulating and Construction Co.—Other New Incorporations.

THE Chicago Underground Railway Co. has been incorporated. The object of the corporation, as the name indicates, is to build under the streets of Chicago a railway connecting all the suburbs with the centre of the city. The projectors say that the road is to be modeled after the Metropolitan railway system of London, but that the disadvantages of the latter line—darkness and smoke—will be overcome by the use of electric motors and electric lights. According to the plan, the tunnels will radiate from a central point and will be located about 100 feet below the surface. If a pocket of quicksand be met, riveted iron tubes will be forced through the bed. The cost is estimated at $1,000,000 per mile. The capital of the organization is $27,000,000. A great many arguments in favor of this system can be advanced, but the great question—whether the road can pay interest on the investment—has not yet been answered to the satisfaction of capitalists. Those interested in the scheme seem confident that the project will eventually be successful. The view which the public takes of the project is well given in the following extract from a Chicago daily paper :—

> The proposition to build an underground railroad system for this city, offers a happy solution to a long-vexed problem. The only reasonable hindrance to giving it an unqualified indorsement lies in the question, "Can it be made to pay?" There need be no doubt in regard to the possibility of doing the work, and in such a manner as shall render the route an acceptable one to many thousands of people who wish to travel each day between the central portions of the city and its suburbs. The introduction of electricity for power and illumination, with the use of elevators for transferring passengers to and from the street level, can be made to obviate all the objections that have been raised against the underground railway in London. Such a line would relieve the pressure of travel on present thoroughfares instead of forming the additional incumbrance threatened by either the street or alley line of elevated road, and if sunk so far below the surface as is proposed neither noise nor shaking would trouble the residents in the city overhead. The cost of construction is a matter for the engineers to decide upon, and then it must be left to the capitalists to say whether or not the scheme is pecuniarily practicable. For the great public, which wants cheap and rapid transit at a low cost and with the minimum of annoyance, there is but one side of the argument that has any weight. That side is the affirmative one.

At the annual meeting of the Chicago Electric Club, the following officers were elected: President, S. A. Barton; vice-presidents, 1st, C. A. Brown; 2d, J. P. Barrett; 3d, B. E. Sunny; 4th, H. Ward Leonard; secretary, W. A. Kreidler; treasurer, F. S. Terry; managers, C. D. Shain, F. E. Degenhardt, E. B. Chandler, J. H. Reid, Theo. P. Bailey, A. K. Stiles, C. C. Warren, W. J. Buckley, M. A. Knapp, Geo. L. Beetle; membership committee, C. C. Haskins, J. W. Clark, Geo. Cutter, W. H. McKinlock, F. W. Horne. Treasurer F. S. Terry in his annual report mentioned the fact that $1,000 had been expended for fitting up the club rooms. He urged the necessity of increasing the membership that the club might have sufficient income to defray all expenses. The report of the board of managers after felicitating the members on the work of the year and the bright prospects of the club, continued as follows:—

> While the finances of the club are not just now in as satisfactory a condition as could be desired, they are not at all desperate, considering the fact that another quarter's dues will be payable at an increased rate in about two weeks. It has been thought advisable to give members who are interested in the club and receive its benefits an opportunity to subscribe for the further furnishing of our rooms. It seems reasonable to expect that $1,000 can be raised in this way, which will leave the club free from indebtedness, and with property to the value of $2,000 on hand. The value of the papers read before the club and of the discussions following them, is sufficient to suggest the expediency of having them printed in pamphlet form, as is done in the Institute of Electrical Engineers. The social, scientific, and business advantages of the club are such as to insure its continued growth and prosperity, and it is predicted that it will soon be necessary for the club to have a house of its own.

S. A. Barton, of the Thomson-Houston company, the new presiding officer of the club, proposes to institute a vigorous policy, which will establish the association on a much more substantial basis and make it an effective and active organization. The club has already accomplished much in the way of promoting a more social feeling among the members of the electrical fraternity, and the association has reason to consider with satisfaction the quality of the papers which have been presented from time to time. A club house is talked of, but as yet nothing definite can be reported on this question.

Preparations are making for lighting the city from its new electric light plant. The appropriation for the plant was $35,000, and the capacity will be 450 2,000 c. p. lamps. In all the streets crossing the river several lights will be located within two or three blocks of the stream. The east side district, first to be lighted, will be between Michigan avenue, Madison street and the river; the west side between Van Buren, Halsted and Washington streets and the river. It is expected that Madison street will be lighted as far west as Western avenue. This will be the beginning of the general system of city illumination.

The first meeting in July was electric light night in the Chicago city council. The ordinance giving the Sun Electric Light Co. the privilege of laying wires to furnish "light, heat, power and signals" between Adams and 22d streets and the lake and the Chicago river was passed. The matter had been slumbering in council committees for months. It was voted that the company pay into the city treasury five per cent. of its gross earnings as consideration for the franchise. The original ordinance provided for the payment of 2½ per cent. A similar franchise was granted to the north side company to operate lights in the north-west part of the city. The same consideration for the franchise was exacted. The Consumers' Electric Light Co. was granted the privilege of operating lights south of Harrison street between Blue Island avenue and Halsted street on the same terms. On the same conditions the Co-operative Electric Co. was granted the right to operate lights on the entire north side, south of Fullerton avenue. Some opposition was made to the passage of the ordinances on the ground that it was poor policy if the city contemplated the installation of an extensive electric light plant to give to rival companies a strong foothold in the heart of the city.

The officers of the Chicago Telephone Co. looked forward to the city council meeting of July 9 with decidedly unpleasant anticipations. An ordinance had been introduced reducing the rates of telephones in the city to $75 per year. The resolution was modeled on the St. Louis resolution which brought on the fight in that city. The aldermen as a body favor the telephone company very little, but fortunately this effort to strike a blow at the company was unsuccessful. Superintendent Phillips, when asked his opinion of the proposed ordinance said: "I am not prepared to say what the company will do if the council passes the ordinance. We will not cross the bridge till we get to the river. I hope and think that before final action is taken a conference will be held and a full statement of the company's side of the case will be considered. It has been my honest ambition to give Chicago the best telephone service in the world, and this statement, I think, is proved by the money which the company is expending. A switch-board costing $60,000 has recently been put in, and other expensive improvements are being made." The ordinance was referred to the committee on licenses, and it will remain there for some time at least.

Alderman Thomas C. Clarke, chairman of the committee on fire and water, of the Chicago city council, died suddenly July 6. He was mainly instrumental in securing for the city the electric light plant which it now possesses. Last year he carried out the idea of lighting the bridges and the river by electricity. He was the author of the bridge telephone system.

Mr. E. P. Warner, of the Western Electric Co., has invented a new focusing arc lamp which is designed particularly for the use of river steamers. It can be used with different kinds of reflectors as occasion requires.

Matthew Gray, well known as an engineer, while making a visit in Chicago recently made the statement that the work of constructing a cable across the Pacific would soon be begun. He was sent as a representative of the Silvertown Submarine Cable Co. to Vancouver and to Australia, to investigate the feasibility of laying the line, and he made a highly favorable report. It is said the cost will be between $15,000,000 and $20,000,000.

Joseph Reinstein has commenced suit against the Chicago Arc Light and Power Co. to obtain $5,000 damages. He was injured in the explosion which occurred about May 1, in the Bell clothing store. The explosion was caused by the ignition of gas leaking from a main which was broken by the employés of the defendant company in forcing a tube for wires under the sidewalk.

A despatch received in Chicago July 11, stated that the Excelsior Electric Light Co.'s building at Port Huron., Mich., was burned. The structure contained eight dynamos, two engines and a considerable quantity of supplies. The electric railway which was supplied with current by the company was disabled. The loss was $10,000 and was covered by insurance. The company immediately commenced to consider plans for rebuilding.

D. H. Lauderbach has resigned as general manager of the Chicago Edison Electric Light Co.

The Van Depoele company will install a 100 h. p. electric plant at Rockford, Ill., for the distribution of electricity for power. The same company has installed an arc light plant on the John A. Dix, an excursion steamer running from Chicago.

The Chicago Insulating and Construction Co. with $250,000 capital stock, has been organized. The incorporators are E. B. Palmer, E. A. Mulford and L. M. Hunter. The company will manufacture insulating materials and supplies.

The 31st Street Electric Light Co. of Chicago, has been incorporated. The capital stock is $50,000. The charter gives the company the right to sell current for motor power as well as light. Those interested in the company are J. J. Shimers, J. J. McEvoy, S. F. King and Owen O'Neil.

The Gaston Electric Headlight Co., of Chicago, has been organized to manufacture electric headlights and electric supplies. The projectors are J. E. Gaston, J. R. De Mier, D. P. Barker and R. J. Harmer.

The Chicago Electric Motor Co. has been formed. The capital stock is $30,000. The corporation will manufacture electric appliances. The projectors are R. H. Garrigue, J. C. Scroggs, J. H. Claswell and H. S. Tiffany.

The American Telegraph and Telephone Co. has been incorporated, with headquarters at Chicago. Those interested in the company are Russell C. Whitmore, William Speirs and Albert R. Rawson.

The Elmer A. Sperry Co., of Chicago, has been incorporated. The company will install electric light apparatus. Those interested in the company are Elmer A. Sperry, George Lawrence and J. G. Marsh.

The Fowler Insulating Co., of Chicago, has been incorporated with $150,000 capital stock. The object of the company is to make insulating and fire-proof materials. The incorporators are Preston B. Rose, Thomas Connelly and Frank A. Fowler.

The Englewood Electric Light Co., of Englewood, a suburb of Chicago, has been incorporated with a capital stock of $50,000. The incorporators are Joseph Badenoch, Jr., John I. Badenoch and Charles T. Page.

The Delevan Electric Light Co., of Delevan, Ill., has been incorporated. The incorporators are J. M. Allen, A. I. Maclay and F. E. Allen.

A certificate of incorporation has been issued to the Brush light company, of Charleston, Ill. The capital stock is $15,000. The object of the incorporation is to deal in motor and electric apparatus, and to operate motor and electric plants. Those interested in the company are E. L. Link, E. Cadle and C. E. Winter.

The contract for lighting the Auditorium building has been awarded to Leonard & Izard. The cost of the plant will be about $50,000. There will be installed 8,600 lights.

CHICAGO, August 22, 1888.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall street, New York city.*

WELDING RAILS BY ELECTRICITY.

[96.]—*Dear Sir:*—In the July number of your magazine, Mr. Elias. E. Ries publishes a long epistle in which he endeavors to expose my ignorance of electric welding and the folly of what he is pleased to call *my criticism* of his " method of electrically welding and tempering " rails, which he states appeared in your June number. I shall not crowd your columns with a reply in detail to Mr. Ries, more especially as those who are familiar with the subject will, I think, consider most of his reasoning answered as soon as stated; but for the sake of those who know but little of electric welding, I would like to exhibit a single specimen of what Mr. Ries would doubtless call my *ignorance* and his *knowledge* of this subject. Before doing so, however, permit me a word of digression. As to Mr. Ries' explanation of my motive in writing my previous letter, and other such personalities which fill about one-third of his letter, I will say nothing. Courtesy would also, it seems to me, enforce silence in relation to the pending interference between Mr. Ries and Professor Thomson; and I must, therefore, positively decline to say anything in regard to this matter. I have no doubt that Professor Thomson will be well able to take care of all matters relating thereto.

It may be well here to make a correction, and state plainly the issue between us. My letter was *not* a criticism of what Mr. Ries calls his " method of electrically welding and tempering " rails; it was not a criticism of any one's method. The general statement was made, and it was this which prompted my letter, that it was proposed to weld tempered steel rails into continuous lines of track with subsequently retempered joints. It was my opinion that important details of the problem had not been considered in the proposition. My letter, therefore, was simply a brief statement of some of the difficulties which would inevitably be encountered in carrying such a project into effect. It is Mr. Ries who drags his " method " into the discussion, and, therefore, I can see no reason why I should not briefly respond to Mr. Ries. The question then is: Does Mr. Ries' " method " meet the difficulties referred to in my letter? To determine this I will examine one of Mr. Ries' statements, and to insure fairness, will take the first he makes.

Referring to my statement that there would be on each side of the joint an annealed portion which could not be tempered without heating the whole track, Mr. Ries says that this may be true with regard to the peculiar tempering process practiced by myself, but adds that if " Mr. Stuart will glance at a copy of the patent above referred to, describing this method of welding and laying railway tracks, he will find, among other things, the two following claims, which not only describe the method by which a uniform, temper *is* produced, but which cover broadly the art of electric welding in which current strength is gradually increased to prevent burning the metal and permanently destroying its tempering qualities at the joint," etc. The claims are then given in full.

I was acquainted with Mr. Ries' patent when I wrote the letter he replies to, but I was then, and am still, unable to find any method of restoring uniform temper to an annealed portion of a steel structure, described either in the claims quoted or in the specification referred to; I have no hesitancy in saying that Mr. Ries has neither described nor practiced such a method. Nor is this all, for if it were necessary, in order to make a method practicable, merely to describe it, perpetual motion would have been a grand success, as the records of the patent office amply demonstrate. Does Mr. Ries suppose that even if a method were described in his claims or specification, that it would of necessity be practicable? But aside from all this, I state positively that a greater piece of electrical nonsense has never been written than this statement of Mr. Ries; and its absurdity lies in this, that the gradual increase of current strength, while it does not destroy, has nothing to do with preserving the tempering qualities of steel. I have frequently welded steel without injuring its tempering qualities, by abutting the pieces, passing through the joint a definite strength of current and gradually *reducing* the flow of this current as the heat went on. It makes no difference how the current is applied, whether gradually increasing, alternately increasing and decreasing, gradually decreasing, etc. Provided the current is of sufficient quantity to effect the weld, and not excessive, *the heating effect will and must be gradual*; and nothing but *heat plus gas* has any effect upon the tempering qualities of steel. Does not Mr. Ries know, that if an amount of current, sufficient to effect the weld is passed through the abutting ends of two conductors, the ends will begin to heat, and a subsequent gradual welding can be effected with even *less* current than was used at the start? The heating effect is equal to $C^2 R$, and it is evident that if R be increased, C^2 can be decreased proportionately. Is it possible that Mr. Ries does not know that a gradual heating effect must be produced no matter how the current is applied, providing said current is of sufficient strength? Or does he suppose that by gradually increasing the current he has conferred upon it a virtue so peculiar and so subtle as to keep intact the tempering properties of the metal in spite of the action of heat and gas?

Looked at from a different standpoint, it is apparent that Mr. Ries has forgotten the conditions under which steel loses its tempering qualities. He forgets that in dozens of foundries in this country steel is melted and poured into moulds with no " gradual increase of the current to prevent burning!" The real cause of the so-called burning of steel is to be looked for in the combination, due to heat, of the metal with extraneous gases, which produces " grit," destroys homogeneity, and prevents an intimate coherence of the particles. In view of this fact, is not Mr. Ries' position manifestly absurd?

I think it is evident that Mr. Ries' scientific opinions are not always to be accepted as truth. In fact, I can see nothing in his letter which could tend to alter an opinion in respect to the practicability of the scheme under consideration. One thing is certain, viz; that the best way to solve the problem is to construct a railway with continuous tempered steel tracks, and endeavor to operate it; and I am glad that Mr. Ries is now engaged in this work, as he seems to intimate. But I venture to predict that the great railroads of the country will not soon adopt what Mr. Ries so glibly calls his "method of electrically welding and tempering metals as applied to the construction of railway lines."

Yours truly,

OTIS K. STUART.

LYNN, Mass., July 17, 1888.

LITERATURE.

REVIEWS.

Die Construction der Magnet-Electrischen und Dynamo-Electrischen Maschinen. Von GUSTAV GLASER-DE CEW. Fünfte, umgearbeitete und vermehrte Auflage von Dr. F. Auerbach. Wien, Pest, Leipzig. A. Hartleben's Verlag.

THIS is a small volume of 253 pages, containing in convenient form information that one might have to go far to find elsewhere. Being a small book it does not pretend to contain a complete list of all the dynamos constructed to date (1887), nor full descriptions of all those treated. The author contents himself with detailed accounts of a few machines, which serve as types, and brief mention of several others developed from them, in which the points of difference are indicated. The present (fifth) edition is an improvement in many ways over the first. The most noteworthy machines introduced in the six years succeeding the first edition have been described in the fifth, and the theoretical and mathematical discussion of the details of construction have been relegated to another volume. This is good on the score both of brevity and of unity of plan. The book is not intended to give dynamo builders instruction in the art, but rather to present for general information the development of the dynamo from its earliest form to the diverse styles in use to-day. It supplies a felt want and cannot fail to be useful to those who desire information regarding the machines in use in Europe and this country. The reader feels a disappointment at times that the information is not complete. One would like to know, for instance, the work that can be expected from each machine. One misses, too, in many cases mention of the nationality of the inventor and place of construction. These facts, to be sure, are given in regard to the most important machines; but it would add to one's satisfaction to learn the same of all without recourse to other sources. Such statistics could have been incorporated without making the book exceed its proper limits.

The subject-matter is included in six chapters and an appendix, and a good index makes the work of reference easy. The first chapter treats of the principles and historical development. The second and third constitute a more or less complete description of some 75 different machines. The fourth takes up some details of construction and instruments for electrical measurements. The fifth and sixth are concerned with the uses to which dynamos have been put. The appendix contains the formulas of Du Moncel for the construction of electro-magnets. Just what appropriateness this appendix has in a book that pretends to exclude theoretical and mathematical discussions, it is hard to see. The space it occupies could have been better filled by information of the kind that fills the fifth chapter.

The first chapter is the least open to criticism. The account of the historical development and the discussion of principles is concise, logical and clear, and serves as a good introduction to the descriptions which follow. In the second and third chapters, besides the omissions already noted, one feels constrained to criticise the classification. The first division made is on the basis of the kind of current generated, and the classification is made of (1) alternating and (2) continuous current machines. The author says (p. 36), "There is needed for a rational classification a grouping of these [machines] according to the nature of the currents generated in them." And again—"Of course, by the use of a commutator a continuous current can be derived from any alternating current machine." On this basis, he proceeds to describe several alternating current machines, including some in which, by means of a commutator, the machines are not only used for plating but for self-excitation. One machine, Möhring and Baur (pp. 47, 148), he puts under both classes. In arranging the sub-classes of the continuous current machines, the division after the mode of excitation is discarded and the machines grouped as, 1, ring machines; 2, drum machines; and 3, machines of various systems. These classifications have obvious advantages; but in view of the fact that they are not mutually exclusive, and are sometimes misleading in name, it would seem that a classification which regarded merely the maker, would be complete and satisfactory. The nature of the current, the mode of excitation, the shape of the armature, etc., could in that case be perfectly expressed in tabular form. Considerable attention is paid to the various forms of the Gramme machine, and those constructed by Siemens & Halske; American inventors are given due credit; but one is surprised to find no mention of the Westinghouse system. Doubtless the author was unaware of its success, for he merely hints that there is a large field open for the alternating current machine by means of the "so-called transformers."

The fourth chapter in which the author states with a few examples, the principles on which the field magnets, armature, commutator, etc., should be constructed, and describes the instruments used for electrical measurements, contains nothing new. The plan adopted of indicating principles rather than multiplying examples is thoroughly adapted to the scope of the book. It is to be regretted that data of tests, such as are given in the fifth chapter, are not more numerous. Those tabulated are very interesting; but they would have commended themselves more to the American reader, had they been represented graphically. On the whole, the book is a contribution to electro-technical literature, and, with its numerous engravings, may prove suggestive as well as a convenient source of information to the electrician.

RECENT PUBLICATIONS.

A Course of Lectures on Electricity, delivered before the Society of Arts. By George Forbes, M. A., F. R. S. (L. & E.). London and New York: *Longmans, Green & Co.* Crown 8vo., cloth, 163 pp. Illustrated. Price $1.50.

Management of Accumulators and Private Electric Light Installations, a Practical Hand-book. By Sir. David Salomons, Bart., M. A., A. I. C. E. Fourth Edition, Revised and Enlarged. London: *Whittaker & Co.* New York: *D. Van Nostrand.* Small Crown, 8vo., 176 pp., 35 illustrations.

Proceedings of the National Electric Light Association at the Second Semi-Annual Convention held at Detroit, Mich., August 31-September 2, 1886, and at the Third Annual Convention held at Philadelphia, Pa., February 15-17, 1887. Boston: Press of *Modern Light and Heat*, 1888. 8vo., paper, 546 pp.

CATALOGUES AND PAMPHLETS RECEIVED.

The Thomson Electric Welding Co., Mason Building, Boston, issue a very tasteful pamphlet circular announcing their readiness to supply machinery and apparatus for electric welding, under Professor Thomson's patents. The circular briefly but clearly describes the principle and methods involved in electric welding, and is illustrated by several extremely fine engravings of the machines offered. Under the headings "Practical Value of the Welding Process" and "Applications to General Metal Working, Shaping, Forging, Tempering, Etc.," much information useful to metal workers is given.

Messrs. Eugene Munsell & Co., 218 Water Street, New York, send us a small thermometer neatly mounted on a sheet of mica of very superior quality. We can hardly call it a catalogue or a pamphlet, but may perhaps include it among circulars, as it bears the advertisement of the firm printed in gilt letters upon the mica sheet.

The Westinghouse Machine Co.'s circular, describing and illustrating their compound engine can not fail to interest general readers as well as persons directly concerned with questions of economic steam power. The gist of the whole is succinctly given in tables of some tests of condensing and non-condensing engines printed on the cover.

ELECTRICAL NEWS AND NOTES.

THE ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.

SEVENTH ANNUAL MEETING.

THE seventh annual meeting of the Association of Railway Telegraph Superintendents was held at the Murray Hill Hotel, New York city, on Wednesday, July 11th. The meeting was called to order at 10 o'clock A. M., by President G. L. Lang, of Boston. The president, upon opening the meeting, feelingly alluded to the deaths of three members of the association during the past year, namely, Mr. Wynkopp, of the Pennsylvania company; Mr. Bartlett, of the Providence and Worcester R.R., and Mr. King, of the Quincy, Missouri and Pacific R.R.

Mr. Lang briefly outlined the business that would be brought to the attention of the association; stating that measures should be taken to bring about more intimate relations with the General Time Convention of the United States, and that some action should be taken to secure uniform electrical time signals from the various

observatories, thereby insuring accurate standard time to all the railroads throughout the country. With that end in view, Commander Brown, in charge of the Naval Observatory at Washington, had been detailed by the Honorable Secretary of the Navy to address the association on the system of transmitting time signals from the observatory.

The following members were present:—G. C. Kinsman, Wabash railway, Decatur, Ill.; P. W. Drew (secretary), C. & E., Ill., Chicago; C. S. Jones, Ill. Central, Chicago; G. E. Simpson, C. M. & St. P., Milwaukee; S. S. Bogart, West Shore, Weehawken, N. J.; J. B. Shaw, N. Y., P. & O., Jamestown, N. Y.; C. W. Hammond, Mo. Pac., St Louis, Mo.; T. J. Higgins, C. C. C. & I., Cleveland, O.; C. A. Darlton, R. & D., Washington, D. C.; N. E. Smith, N. Y. & N. H., New Haven, Ct.; E. A. Smith, Fitchburg railway, Boston; J. D. Gibbs, Mo. Pac., Sedalia, Mo.; E. M. Herr, C. B. & Q., Chicago; A. R. Swift, C. R. I. & P., Chicago; H. C. Sprague, K. C. Ft. S. & C., Kansas City, Mo.; H. P. Houghton, Wabash railway, Butler, Ind.; G. T. Williams, N. Y. C. & St. L., Cleveland, O.; C. E. Topping, now superintendent U. S. Express Co., N. Y.; Robert Stewart, C. R.R. of N. J., Elizabeth, N. J.; J. J. Stenson, L. I. R.R, New York; J. W. Lattig, L. V. R.R., Bethlehem, Pa.; F. P. Cummings, N. Y., N. H. & H. R.R.; Horace Johnson, Grand Central Depot, N. Y; I. Cohen, H. & T. Central, Houston, Tex.; M. B. Leonard, N. H. & M.V., Richmond, Va.; W. J. Holmes, N. Y., L. E. & W., N. Y.; C. Selden, B. & O., Baltimore.

The following new members were elected:—A. E. Smith, New Haven; N. B. Patterson, Mattoon, Ill.; Robert Stewart, Elizabeth, N. J.; F. W. Wilson, Fort Wayne, Ind.; J. E. Duval, Ottawa, Ont.; W. B. Blanton, Dubuque, Ia.; J. A. Lockard, Atlanta, Ga.; J. G. Pinkerton, Amory, Miss.; C. H. Hopkins, Norwich, N. Y.

After the reading and acceptance of the report of the secretary and treasurer, Mr. Bogart, from the committee appointed last year to examine the various devices used for recording the signals transmitted over telegraph wires, made a verbal report. He had examined the self-starting register manufactured by different establishments, and that made by the Western Electric Co. would be included in the exhibit of that company, which, with many others, would be ready for inspection Thursday morning. It was the intention to have the register operated by an electric motor in lieu of a spring or weight.

President Lang, after announcing that the various exhibits would be ready for examination at nine o'clock the next morning, introduced to the meeting Commander A. D. Brown, of the Naval Observatory, Washington, who, he said, would explain to them some of the features in connection with the distribution of standard time.

Commander Brown, in taking the floor, said that he assumed that they would be more interested in the sending out of the time signals than in the methods pursued in obtaining the correct standard. He, therefore, confined himself to saying that they depended upon the stars for their observations rather than upon the sun, as is more generally supposed. These are made every evening at as early an hour as possible. At 11 o'clock P. M. the standard clock is compared with the sidereal clock, and the operation is repeated at 9 o'clock the following morning, the comparison being made by the chronograph. By this method the error existing at the time is ascertained. Any change in the density of the atmosphere, as shown by the barometer, has a great effect on the clock. Every day at 11.40 A. M. the officer in charge of the transmitting clock is informed of the error. The standard clock is allowed to run on from year to year without alteration. A great many people put weights on the pendulum to counteract the difference in the rate. At Washington they allow the standard clock to run on and accumulate the error. The transmitting clock is set every day at 11.40, and is kept on Washington time. This clock runs within one-half to one second. In setting it the pendulum is accelerated or retarded until it is brought into unison with the standard when they are compared by the chronograph. At 11.45 they are as near together as it is possible to get them. This process is repeated every day whether the observation is made or not. If the weather be cloudy the clock must be run on its own record. On one occasion when no observation could be taken for eight days, they found the clock about eight-tenths of a second out, while at another time there was a difference of but one-tenth. The discrepancy arose from the fact that the allowance made for the change in barometer was not so correct in one case as in the other. The time sent out is as accurate as possible. The transmitting clock is entirely automatic in its action; there is no handling of the key.

They also have a clock system for the local distribution of time, which has finally been adopted after many years of experimenting. The clocks used upon it are the ordinary eight-day clocks, which are synchronized by the transmission of an electric signal at noon each day. They have been in operation about four years. There are about 400 of them altogether, of which 200 are in the government service. During the last year there has been quite a demand for these clocks by the railroad companies. He believed that when the true merits of the system were more generally known among railroad people they would come into more general use. He considered it exceedingly important that they should have the best that could be devised.

It is best to have a standard, even if it is not a good one. The Naval Observatory has given time for many years to the Western Union company, and the Baltimore and Ohio company up to the time of its amalgamation, and is open to all who ask for it. He did not think that the importance of standard time could be overrated. It is not because they can do better than any one else, but for the reason that they have a large force to give it their entire attention. In answer to inquiry by the president, Commander Brown said, that the clocks in question could not be operated by the signals sent from all observatories. One of their clocks had been left at Altoona to be tested by the Pennsylvania railroad, but it did not give satisfaction, as the signal stroke sent from the Alleghany observatory was not suitable for it.

The president stated that all roads running out of Boston obtained their time from the Cambridge Observatory.

Commander Brown, in reply, said that every observatory has a different signal, each from the other. The Naval Observatory has had the railroad service in view for many years.

Mr. Jones, of Chicago, having stated that the Limited Time Co. obtained its signals from three observatories, viz., Washington, Madison and Evanston.

Commander Brown said it was very bad practice obtaining time from three observatories. This had been proved by experience at New York, where the local time service is in charge of Mr. Hamblet. At one time he received signals from five different observatories. He made a record every day of the error, and it was evident, from looking at it, that by taking the mean we should get into trouble.

Mr. Smith, of New Haven, stated that there was almost invariably a difference of one second between the time from Washington and Yale observatories.

Commander Brown stated that at Washington they pay more attention to accuracy and details.

At one observatory the weather may be cloudy and another clear. It is better to take the time from one observatory and stick to it.

Mr. Jones, of Chicago, said that the matter of standard time was assuming considerable importance in the west, and when a proper system was shown, it would be generally adopted. He was not aware whether it was safer to rely for accuracy on the enthusiasm of professors or the competition developed between private parties.

Mr. Herr, of Chicago, stated that he had been using about four months eight self-winding clocks located at various points, which had been synchronized by signals from Chicago; lately, however, Mr. Pond has started a time company, and is now receiving time signals from two observatories. He proposes to synchronize. His business, comprising different systems and clocks, has been doing very well. They synchronize only when the variation is less than half a minute.

Mr. Darlton said that the Gardner clocks were in use on the Richmond and Danville line over an extent of 2,500 miles. They are set at noon each day. The signals are sent over the railroad wire from Washington. The synchronizing device may be attached to any clock at a very small expense.

In reply to a question by Mr. Jones, Commander Brown said that the transmitting attachment added to a fine clock did not retard it, as the work required was so very slight. The attachment is not connected with the pendulum. It is on the seconds arbor, but not in the train. Mr. Williams, of Cleveland, thought that Professor Gardner's attachment required a very long contact on the 60th beat. The signal which they received from Washington, was a very short dot, not even a Morse *e*; it should be as long as a Morse *t*. Mr. Jones enquired if the magnetic influence which caused variation in the rate of watches would apply in any case to clocks.

Commander Brown replied that there would be nothing of the kind in the case of a clock. There was no doubt as to the variation in watches caused by magnetism, especially with watches used on a railroad. He had made a great many tests of the Giles' anti-magnetic shield, and also the Geneva non-magnetic watches. The Giles watches performed as well as a watch could, so far as their protection under ordinary circumstances was concerned. The shield was not, however, a thorough protection under all circumstances. He magnetized all of them, but had to place them close to the poles of the dynamo in order to do it. The non-magnetic watch was not affected at all. The first he tested he could stop in a magnetic field, the other sent to him he could not stop. The difference between them was explained by the fact that a steel fork was used in the mechanism of the first watch The question is not settled as to how these watches are going to wear, as they have been in use but a comparatively short time. Unless we put a shielded watch very close to a dynamo it will not be affected by the magnetic influence. There is no question but that the Geneva watch is compensated for temperature. The balance wheel is made of two different alloys of palladium sweated together.

Mr. Leonard, of Richmond, said that he made tests with the Giles shield, and had never found it subject to the influence of a Thomson-Houston machine.

Mr. Herr replied that in his test he had used the Ball dynamo,

in which the field is much more intense than in the Thomson-Houston machine.

Commander Brown explained that compensation for temperature is very difficult to obtain. He had just finished testing 40 chronometers which were compensated for a temperature of 70 degrees. The makers have told him that in respect to compensation they work in the dark. We cannot get a watch or chronometer that will run within a second at all temperatures without an auxiliary balance. Palladium has been used as a balance spring for chronometers with the idea that it would not rust; but the metal was not satisfactory as a spring. It does not act the same as steel, and its use for that purpose in chronometers has been abandoned.

The president enquired of Mr. Bogart, whether the time signals from Washington were sent direct through the New York office to New England, or whether repeaters were used.

Mr. Bogart replied that the signals passed through four repeating points in the New York office.

Mr. Jones stated that in 1869, while at Albany, he carried on experiments for a year or two in conjunction with the professor in charge of Dudley Observatory. They made up a metallic circuit of 2,000 miles, and they fixed the speed of the signals over this wire at 36,000 miles per second, $\frac{1}{100}$th of a second being consumed by the movement of each armature in the circuit. Very careful observations were made. The armature time must be taken into account, and if its movement is sluggish the time occupied is more than $\frac{1}{100}$th of a second.

There being no further discussion of the time question, Mr. Topping announced that the Hon. J. H. Starin had extended to the association an invitation to visit Glen Island. Transportation had been provided for 120 guests, and the steamer would be at the foot of East 32d street at 3.15 P. M.

The Long Island Railroad Co. had also extended an invitation to visit Manhattan Beach. Superintendent Holdridge of the Woodruff Palace Car Co. had provided coaches which would be in readiness at Hunter's Point, at 5 P. M. on Thursday.

The president announced that an invitation had been received from Mr. Henry Harley, to visit the tunnel on the West Shore road, and examine the working of the signals at that point.

Mr. Bogart stated that superintendent C. W. Bradley would furnish an engine and coaches. The signals referred to were a new departure. They count every pair of wheels that goes on a block, and report the same number as they pass off.

The thanks of the association were voted to the various parties extending the invitations, and it was decided to visit the West Shore signals on Friday. At 1 o'clock P. M. the meeting adjourned until Thursday morning at 10 o'clock.

SECOND DAY'S PROCEEDINGS, THURSDAY JULY 12, 1888.

The meeting was called to order at 10.30 A. M., by President Lang, who announced that the next business would be the report of the committee appointed last year to report upon the adoption of a substitute for the long dash now used as the character for the "cipher."

Mr. Selden reported on behalf of the committee, that they had conferred by letter. They had called upon representatives of all the telegraph companies, and presented symbols suggested by different parties. Every new character suggested, however, conflicted with something already in use. If the letters were made correctly by an operator no trouble would arise from the confliction of characters now used. A feeling existed among all people identified with telegraphy that we should not make any change in the Morse alphabet. Upon motion of Mr. Bogart, the committee was discharged.

A telegram was read from O. C. Green, N. P. R. R., calling attention to the fact that superintendents did not act promptly in reporting discharged men. A general discussion ensued in which the practice of reporting the discharge of operators through the secretary's office was commented upon by the different members present. It was maintained that this system was not a black-listing scheme, as has been generally stated, but merely a system by which the records of applicants for positions could be determined without loss of time, and voluminous correspondence. It was decided to make no change in the existing methods, but it was generally understood that the superintendents would co-operate with the secretary in distributing prompt information of this character. The following officers were elected for the ensuing year: G. C. Kinsman, Decatur, Ill., president, C. A. Darlton, Washington, D. C., vice-president; P. W. Drew, Chicago, Ill., secretary and treasurer.

Mr. J. W. Lattig, on behalf of the Lehigh Valley railroad, invited the association to make a trip to Easton over that line and inspect the working of the train telegraph in practical use. The invitation was accepted, and the members notified to take the one o'clock train from Jersey City on Friday.

In reply to an enquiry by Mr. Selden as to their experience with the train telegraph during the blizzard last March, Mr. Lattig said that it was their only reliance for telegraphic communication for three days. All the relief and supply trains were governed through the medium of the train telegraph, and its operators were on duty night and day. A serious accident occurred at this time, and there was no other means of communicating with the wreck. The wire was broken once on Monday at Boundbrook by other wires falling upon it. Their experience had been that this system works better in stormy than in dry weather. The use of it for commercial telegraphing was gradually increasing. None of the previously existing telegraph offices had been abandoned by reason of its introduction, because the growth of business on the road required constantly increasing facilities. A gravel train had been equipped with the apparatus, which was engaged in the construction of an additional track. One hundred men were employed on this train, and during the first week one hour and forty minutes of time was saved by the train obtaining permission to remain on the main line. Working time for this train has been saved every week since it was fitted up and provided with means of constant communication with the despatcher's office. All of the wrecking trains have now been equipped with these instruments, so that after being ordered out they are in communication with headquarters until the wreck is cleared away and the train returns.

The committee appointed to fix the time and place of the next meeting reported in favor of holding it at Atlanta, Georgia, on the third Wednesday in October, 1889.

Messrs. Lockard, Leonard and Darlton were appointed a committee of arrangements for the next meeting.

Mr. R. W. Pope was granted permission to address the meeting in order to call attention to a misunderstanding which appeared to exist in regard to the work of the association. He alluded to the fact that the application of electricity to railroad work was continually increasing, and pointed out that it would be for the best interests of its members to give greater attention to these matters in order to make their meetings more profitable and keep abreast of the improvements which were continually being brought out. His attention had been called to this subject by the appearance of an article in the *Railroad Gazette*, describing an incandescent plant which had been introduced in the railroad yard at Oakland, Cal., for lighting the signal lanterns by electricity, which had proved to be more economical for the purpose than oil. He stated that a similar plan was in contemplation by the Penn. Railroad Company for the Jersey City yard.

A discussion followed upon this subject which led to the adoption of the following resolutions :

Resolved, That the chair appoint a committee of five on electrical information, whose duty it shall be to disseminate matters brought to their attention by members of this association.

The chair appointed to serve on this committee, Messrs. Leonard, Lattig, Bogart, Swift and Higgins.

Resolved, That the chair appoint a committee of three who shall select subjects and writers upon the same, said papers to be read at the annual meetings.

The chair appointed as such committee, Messrs. Herr, Selden and Lang.

Following out the line of policy as intimated by the previous discussion, Mr. G. L. Lang presented the following paper on "Electric Welding," as being a subject of general interest to the mechanical departments of railroads, as well as the electrical.

ELECTRIC WELDING.—BY OTIS K. STUART.

THE process of electric welding, which was discovered by Professor Thomson some 11 years ago, while lecturing at the Franklin Institute of Philadelphia, has been developed in the past two years to a far greater extent than is generally supposed. We started in with the welding together of small wires of iron and copper, and have been so successful in the development of apparatus, that we are now able to weld bars of a very large size and of almost any shape or metal.

The principle involved is that of forcing through a conductor an amount of current which the conductor will not carry without heating. Any conductors when placed in abutment, have as their point of greatest resistance the point of abutment or contact, and consequently it is at this point that the heat is first generated; and as is well known, this heat increases the resistance of the conductors at that point so greatly, that more heat is developed at a remarkably rapid rate.

A consideration of the above facts will prove at once one of the advantages of electric welding, as practiced by Professor Thomson, namely, the localization of the heat to the points or point at which it is desired, thus saving an enormous amount of energy which is usually wasted in welding with the forge or flame. So absolutely is the heat localized, that pieces of iron 3" long and an inch in diameter, can be welded together and then held in the hands for some time without any danger of burning, the only heat which is felt at all being that which is conducted along the metal to the hands after the welding is completed.

A further consideration of these facts, will also demonstrate that it is possible by the Thomson process to weld any metal, including even those which melt at a very low temperature such as lead, zinc, and tin, and those which melt at enormously high temperatures, as for instance, iridium, platinum, etc. Of course it goes without saying that we can weld any of the metals used in ordinary manufacture.

It is plain that if the heat is developed so rapidly, a very deli-

cate means of controlling it must be provided, and we are glad to say that we have been able to provide arrangements for this purpose which are almost absolutely perfect,—I am inclined to say absolutely perfect, for the reason that the control of the current can be made entirely automatic.

We are able to take a bar of inch iron 4" in length, raise it to a dull red in 20 seconds and hold it there for an indefinite period; to increase the heat to a bright red in a very few seconds and hold it there; then to still further raise the temperature to a welding or vaporizing point, in a remarkably short space of time; this indicates the delicacy of this apparatus, and I would add that no very great skill is required to operate the machine, a boy learning to weld iron and steel with great facility in a week or two. The time required to weld metals, depends, of course, upon the power of the apparatus and the skill of the operator. We have made strong and practically perfect welds in half-inch round wrought iron in six seconds; in inch round wrought iron in 45 seconds; and so on. Experiments have proved to us, that the power required to weld is proportional, or very nearly so, to the area of cross-section of the pieces; this is true of nearly all the metals, though, of course, the relative resistance and welding temperature of the several metals may interfere with this ratio.

For welding small wires such as telegraph or telephone, and the smaller sizes of electric light and power lines, the power required is very small indeed; the momentum of heavy machinery being more than enough to effect the weld. In this connection I desire to say that we are now working to perfect an apparatus for welding telegraph, telephone and electric light wires, and lines of pipe on the line. Our experiments in this direction have been successful, and we now think it possible to construct an apparatus which will be capable of being moved about by one or two men, and which will make joints in wires correctly and durably, the energy used being supplied by storage battery or batteries, forming a welding outfit. For repair work and in general construction it is our belief that this apparatus will be found very useful and effective; in fact we hope to do away entirely with the ordinary solder and link joints used at present.

The cost of such an apparatus will be very slight, and there would be a small royalty of a definite amount per 100 or 1,000 welds, as the case might be. This policy of placing an apparatus on the market has been adopted for the reason that our patents cover not only the apparatus for electric welding, but the art or process as practiced by Professor Thomson. It is hardly necessary to add that by the same process, we can solder and braze and anneal, and temper, and do other heating, local or otherwise, which cannot be done economically by present methods. All these operations can be performed with the same apparatus, though, of course, it is better to have machines specially constructed for particular work.

At the conclussion of the reading Mr. Lang stated that he had seen one of these machines in operation when a bar of cast steel and one of copper were welded together. One would suppose that the metal most easily fused would burn away before the other was brought to a welding heat. This is not the case, however, and it is very simply provided against. The current is brought to the bars through clamps which grasp the bars near to the ends to be welded, and the current is brought through these clamps. Where copper and steel are to be welded together, the clamp is placed about 6 inches back on the copper bar, while it is only about one inch from the point of contact on the steel bar. In this case the heat is diffused through a large body of the metal which is most fusible, so that they are both brought to a welding point at the same time. The process is something really wonderful, and promises to revolutionize the ordinary method. In reply to an enquiry by Mr. Lattig, Mr. Lang stated that the system is now in constant use at the Thomson-Houston factory in Lynn.

On motion of Mr. Lang, a committee of three was appointed to draw up suitable resolutions of thanks for the many courtesies extended to the association during their visit to New York city. The committee was composed of Messrs. Selden, Lang and Jones.

By permission of the meeting, Mr. F. E. Kinsman read a paper on an electric automatic brake-controlling device, which he claimed, would make the existing air-brake and block signal system still more effective than they now are.

The paper was referred to the committee on electrical information.

The meeting then went into executive session, and subsequently adjourned, to meet at Atlanta, Ga., October 16th, 1889.

.... An invention is essentially the product of the age in which it appears; a necessary consequence of the inventions and discoveries which have preceded it.—*Silvanus P. Thompson.*

.... If we look at the real nature of all commercial transactions, we shall find that the real thing which is the subject of a trade, lies back of the material thing to which the price is affixed, and rests in the ideas which are embodied in it and are expressed by it, and through which some physical fact or law of nature is made serviceable to man.—*Chauncey Smith.*

HIGH POTENTIAL SYSTEMS BEFORE THE BOARD OF ELECTRICAL CONTROL OF NEW YORK CITY.

At the meeting of the board, June 8, Commissioner Gibbens read the following letter which appeared in the *Evening Post*, signed by Harold P. Brown, "electrical engineer," 201 West 54th street, New York.

To the Editor of the Evening Post:

Sir:—The death of the poor boy Streiffer, who touched a straggling telegraph wire on East Broadway on April 15, and was instantly killed, is closely followed by the death of Mr. Witte in front of 200 Bowery and of William Murray at 616 Broadway on May 11, and any day may add new victims to the list. After every such accident the newspapers clamor to have the wires placed underground, while the electricians connected with the system at fault hold their peace or throw the blame on the telephone wires, until the matter has been forgotten. As an electrical engineer I know that burying the wires would not remedy the trouble, though it would largely diminish the risk, while the enforcement of a few common-sense regulations would make it almost impossible to kill a man from an arc light current. It will not do for electricians to state that they "don't know what killed that man," for unless they take prompt measures to make their business safe some terrible accident will cause the adoption of laws to regulate electric lighting, which, being framed by their enemies, will cripple or destroy their business.

So, at the risk of offending some corporations having heavy investments in unsafe systems, I will venture to state a few facts which I trust the press will be kind enough to publish widely, as no disinterested electrician will deny my statements.

It is well known that a continuous current of "low tension," such as is used by the Edison company for incandescent lights, is perfectly safe as far as life risk is concerned. From this fact the false popular impression has arisen that all incandescent systems are safe and all arc systems dangerous. But it is not to the "low tension" alone that this current owes its safety, since a factor fully as important is the even, steady quality of its delivery. That is, a current of "high tension," but unbroken and continuous, *may* be perfectly safe if properly operated, while a current of lower "tension," but wavy or pulsating, is *always* dangerous. And when these pulsations rise in speed and intensity the danger increases, until the climax is reached in what is called "alternating current" in which impulses are given first in one direction and then in the other several thousand times a minute.

To understand the reason for this it is necessary to remember that when a current through a wire or other conductor is made or broken, a current in the opposite direction is "induced" in any parallel conductor; the same effects are produced in a less degree when the first current pulsates, but are intensified when it is alternated or reversed in direction. Any one who has held the metal handles of a "medical" (Galvano-Faradaic) battery, has had a practical experience of the power of induction and pulsation; in this apparatus the current from the battery itself is so feeble that it cannot be detected without the use of instruments, except by the metallic taste when the terminals are touched by the tongue. This insignificant current is passed through a short piece of insulated wire coiled around an iron core, and is interrupted by a rapidly vibrating armature, thereby inducing in another and longer coil of wire surrounding the first a series of shocks whose intensity can produce most intense suffering or even death in a human being who forms a portion of the circuit. It is this rapid succession of shocks that kills, while a single steady impulse of the same intensity would do little damage.

Two of the leading arc-lighting systems have dynamo-electric generators provided with what are known as "open-circuit armatures," which produce a pulsating current somewhat similar in kind to the one just described, though a thousand times more powerful. It is to this current that nearly all the deaths caused by arc lighting systems must be attributed. These "open-circuit armature" systems, were pioneers in electric lighting, and at the time they were invented it was supposed that the "closed-circuit armatures," which produce the steady and safer current, could not be made to develop sufficient electromotive force to operate a number of arc lamps upon one circuit. But the recent advances in the science have made possible "closed-circuit armature" generators which give the same amount of current and electromotive force, with a much less expenditure of motive power, so that there is now no valid reason for the existence of the old type with its pulsating and dangerous current.

I do not mean to have it understood that the "steady" current is always safe or that the "pulsating" is always unsafe, for any current with more than 50 arc lamps in series is dangerous and should be prohibited; while the "pulsating" current, if its circuit is kept thoroughly insulated and carefully watched, and tested every day, may run for years without a fatal accident. But the fact remains that the "steady" current, with 50 or less lamps in circuit, has had, to my knowledge, but four victims against the scores killed and maimed by the "pulsating" current. And even these four were responible for their fate, since all were employés and should have known better. Three of them tried to disconnect apparatus through which they knew the current was flowing, and thus got into the circuit, while the fourth received the full current while trying to repair a broken wire which he knew was charged.

But the persons killed by the other system, as a general thing, have been in no way responsible for the accidents that caused their deaths; they have, as did young Streiffer, touched or run against an apparently harmless wire when standing on a damp place, or have touched at the same moment some metal accidently charged with the fatal current, and some other conductor having a "ground" connection, as did Mr. Witte. I do not believe with extremists that the "pulsating" current should be prohibited, but I do think that the conditions of safety should be rigidly enforced by the authorities.

If the circuit carrying the "pulsating" current is perfectly insulated at all times, no accident is likely to occur. But if, through wearing of the insulation or a heavy rain, a connection between the circuit wire and the "ground" is formed, any one who touches the wire and a "ground" will receive a portion of the current; if he happens to be near the other "ground," he receives but a small shock, but if there are a number of lamps between him and the other connection, the shock may be fatal.

Of course the reply will be made that all the arc lighting stations in this country use insulated wire, "as required by the underwriters," but here is just where a great mistake has been made, and the sooner this is corrected the better for the cause of electric lighting. It is an open secret among electricians that the wire known as "underwriter's wire" has a very poor insulation, even when new and during dry weather, but practically no insulation at all during a rain. The paint dries out of it after a few months' exposure, other wires rubbing against it soon wear away the cotton and expose the metal, and it is altogether unfitted for outdoor use. Among electric lighting men it is appropriately called "undertaker's wire," and the frequent fatalities it causes justify the name.

Even with the most conscientious electric light superintendent, who tests his circuit carefully for "grounds" every day, before starting the generators, there is no surety that during the run some telegraph wire may not drop upon his circuits, wear away the insulation, and set a death-trap for the unwary who may be miles away from an electric lamp.

The condition of the electric light circuits in the lower part of the city is simply disgraceful, as has been previously pointed out. Most of them were first put up years ago; they have been cut and patched until full of joints, from which the tape flutters; the insulation is entirely worn off in places or hangs in shreds, and few circuits are fit to run with safety for a single hour. They cross and recross the structures of the elevated roads; they sag and sway in loose loops, and are intersected at all levels by telephone and telegraph wires. On some of these circuits two or more dynamos are run in series, thus more than

doubling the life risk, and it is almost certain that it was these overloaded circuits that killed Streiffer and Witte.

If the Board of Electrical Control cannot force the wires underground, they can at least condemn these lines, which the companies can afterwards utilize by reinsulating for their underground circuits. The underwriters ought to have an eye to this also, for every bare or poorly insulated spot is a menace to property as well as life.

But if "influence" prevents the wires from being replaced, and it seems to permit the extension of new wires elsewhere, there are a few simple precautions which, if enforced, will make fatal accidents almost impossible. All the deaths due to arc lighting, as far as reported, have been caused by the victim breaking the circuit and placing himself in the break to receive the fatal "extra-current" thus caused, or by his making a "ground" connection with a circuit on which there was another "ground." Both of these dangers can be avoided by very simple apparatus.

If a voltameter, or a circuit of very high resistance, be connected across the poles of every arc light dynamo, the external circuit may be opened without producing the death-flash, as most of the "extra current" will go through the by-pass. This would prevent a large proportion of the fatal accidents. If every arc light dynamo was also provided with a wire of very high resistance leading from the circuit to the "ground," upon which was interposed apparatus to shut off the production of current the instant a second "ground" occurred, no deaths could be caused except by foolhardy carelessness. The latter apparatus could also be used to shut down the current in case the external circuit should be broken.

With these precautions, and with the number of lamps limited to 50 on a single circuit, even the "pulsating" current would be fairly safe, but as the stations are now operated upon circuits with frayed and worthless insulation they are a constant menace to all who walk the streets, use a telephone, or touch a wire.

In regard to the popular impression that all incandescent electric lighting systems are safe, I am sorry to say that recently several companies who have more regard for the almighty dollar than for the safety of the public, have adopted the "alternating" current for incandescent service.

If the pulsating current is "dangerous," then the "alternating" can be described by no adjective less forcible than *damnable*. With the "pulsating" current three contingencies must ordinarily arise to produce fatal results: there must be a "ground" connection on the circuit; a person must touch the circuit at some distance from the first "ground," and must at the same instant be in connection with the "ground" himself. But the "alternating" current produces fatal results by simply touching the two parallel wires, always close together, connections from which enter every house. Its supporters may say that on account of its danger they do not permit the "primary" or death-current, to enter the house, but supply the lamps from the "secondary" current. True, but between these two circuits is interposed nothing more than a thin layer of cotton or silk insulation, and, as happened again and again, it requires but a flash of lightning or a little moisture in the converting apparatus to bring the death current to each lamp.

The only excuse for the use of the fatal "alternating" current is that it saves the company operating it from spending a larger sum of money for the heavier copper wires, which are required by the safe incandescent systems. That is, the public must submit to *constant danger from sudden death* in order that a corporation may pay a *little larger dividend*. I do not know of a single disinterested electrician of high standing who does not condemn the alternating system. Siemens and Halske, a firm of electricians with a world wide reputation, have spent years of experiment upon it, but have abandoned it as unsafe, and say that its use should be prohibited by law.

Following the example of Chicago, the Board of Electrical Control should forbid the use of the fatal alternating current, and legislatures, city councils, and life insurance managers should see to it that stringent laws and regulations be passed to prevent this wholesale risk of human life. The placing the wires of the alternating system underground would only intensify the danger in houses where it might be used, while its use with underwriter's wire in a city like this is as dangerous as a burning candle in a powder factory. If the death of these three men can effect the adoption and enforcement of regulations similar to the following, they will not have died in vain.

RULES FOR STATION LIGHTING.

Not more than 50 arc lights shall be operated upon any one circuit, unless said circuit is used exclusively for street lamps mounted upon wooden poles; in this case the number must not exceed 60.

All out-door arc light circuits must be provided with waterproof covering having an insulation resistance of not less than one-half a megohm. Any circuit falling below this must not be used until restored.

No arc light dynamo shall be operated unless provided with a voltameter across its terminals, or other device, to provide a path for the extra current caused by opening the external circuit.

No arc light dynamo shall be operated unless provided with means for automatically stopping the production of current the instant a ground connection is made upon its circuit.

No arc light dynamo shall be operated unless provided with means for automatically breaking or short circuiting the field circuit the instant the external circuit is broken, in order to prevent a current from being built up by the broken circuit ends falling upon some conductor.

No alternating current with a higher electromotive force than 300 volts shall be used.

HAROLD P. BROWN, Electrical Engineer,

New York, May 24. 201 W. 54th street.

After the reading of the above, commissioner Gibbens moved the following resolution which was adopted unanimously:

Resolved, That the rules suggested by Mr. Brown be published in the minutes; that marked copies be sent to the superintendents of the different electric light companies of the city, to the Westinghouse company, which proposes to use alternating currrents, to Mr. Park Benjamin, who drew up the rules and regulations of the commission, to Mr. Ralph W. Pope, who has frequently aided the commission by his advice, to Professor Plympton, of the Brooklyn commission; and that accompanying the marked copy of the rules as proposed by Mr. Brown, the secretary be directed to invite the attention of these gentlemen to these proposed rules and regulations, and to ask them to give the board such a reply on the subject as they may see fit, either in writing or by appearing before the board to discuss the matter; and that in order that Mr. Brown may have a chance to meet with these gentlemen, if he so desires, that the same be sent to him.

Invitations were extended to the various lighting companies interested, as provided in the resolution, and a day appointed for the hearing of arguments as to the necessity of adopting the rules proposed by Mr. Brown. The meeting was held in the lobby of Wallack's theatre, on July 16, about 25 persons were present.

Upon the calling of the meeting to order, commissioner Gibbens announced that the board was ready to listen to all who were interested in the subject. Communications were then read before the meeting as follows:

608 Chesnut street.
PHILADELPHIA, PA., June 12th, 1888.

WM. H. BROWNE, Esq.,
New York city, N. Y.

Dear Sir;—Your favor of the 9th to hand, in which my attention is called to an article in the New York *Evening Post* of June 5th, 1888, headed, "Death in the Wires," signed by Mr. Harold P. Brown, Electrical Engineer, which contains some very sweeping assertions, and also lays down the law in a manner, to which I am sure no practical electrical engineer would commit himself.

Mr. Brown's statement that no disinterested electrician will deny his statements, I think is very correct. Some of his statements are hardly worth denying, and it is only the fact that they are apparently published in the interests of a particular corporation, and for the purpose of taking advantage of the fears of an uninitiated and justly anxious public, that makes it worth while to answer any of them.

If Mr. Brown had confined himself to showing that the three deaths he quotes were all caused by neglect of the commonest precautions, he would have done far better service than by entering into a quasi-scientific disquisition which the general public cannot understand, and which is so full of absurdities as to show that he has either the little knowledge which is so dangerous a thing, or is a deliberate attempt to make a good case by false inferences. The one point plain in his article is that the system of one particular company is perfectly safe and the systems of all others are dangerous, and that one in particular should be wiped out of existence. One of the deaths which Mr. Brown cites, that of Mr. Witte, was reported as caused by a "closed circuit" "shunt wound" machine, the very one which he calls the "steady current" which "has only four victims against the scores killed and maimed by the pulsating current," the fact being that the "pulsating current" has tens of thousands of arc lamps where his much boasted "steady current" has thousands. It is as though he had claimed that only four men had been killed while traveling on horseback in New York city, while scores had been killed on the elevated roads—therefore, it is safer to ride horseback than by railroad.

I have been running electric lights, both arc and incandescent for the past seven years, and have never known of a case where it was conclusively proved that a man was killed by the electric current without there having been gross carelessness in some direction. Mr. Brown could very easily account for every death that has occurred in New York (as far as I have been able to follow them) by the condition of the wires alone. Any man who would undertake to run belts carrying thousands of horse-power, even in a factory, where none but skilled help are employed, in the unprotected way in which wires are run overhead in New York city, would be universally condemned. I never walk in the streets of New York, but my blood boils to see the criminally dangerous and reckless manner in which wires are strung through the streets. They are placed, not on poles, but mere stumps; and wood exposed to the weather, seems to be considered a good enough insulator. The so-called underwriter's covering seems to have been originally the standard, and even that is worn off in many places for several feet along the wires, while the whole air is full of dead and rotten telegraph, telephone, burglar alarm and district call wires, any one of which by falling across an arc light circuit, becomes itself as dangerous. It is absurdity for Mr. Brown to talk about lighting stations and "simple rules and precautions" to be enforced therein. No precautions at the station, however valuable they may be in themselves, can render electric lighting safe, when the outside circuits are in this condition.

It is this outrageous and inexcusable carelessness which has led to the cry for "underground wires," a cry which has so much real foundation that we may well excuse the often rabid insistance of its utterers. The fact that the wires are in this condition in the largest city in the country, is taken as proof that they are in a similar condition in every city, and cannot be made safe, and paper after paper reiterates the senseless shriek against the horrible danger of overhead conductors, without any reference to the manner in which they may be installed.

An overhead wire with properly soldered joints and water proof insulation, with insulated tie wires, and kept clear from all ground contacts on buildings or trees, and out of reach from the ground, is as safe as any underground conductor that can be made, except in case of damage caused by fire, storms or external violence, in which cases the underground conductor has such an overwhelming advantage, that this plea alone should be sufficient to cause them to go underground.

I am an earnest advocate of underground wires and an interested one, but the claim that wires are dangerous, simply because they are overhead, will only hurt the cause, for that reduces it to the level of the outcry against the introduction of railroads, or gas, or any new improvement. There are enough fair arguments against overhead wires without resorting to clap-trap or trickery.

If Mr. Brown kept himself posted as any one who wishes to pose as a general electrical teacher should certainly do, he might have noticed a report in one of the electrical papers of a painter who fell from the roof of a building in Pittsburgh, and who saved his life by catching hold of the two opposite leads of an overhead circuit carrying one thousand volts of alternating current, by which he hung until taken down unhurt with a ladder. This is what I call good practice in overhead construction. High insulation and such solid work that your wires can stand the strain of a man falling twenty feet onto them, without tearing them loose.

Now for Mr. Brown's attack on what he has been pleased to call the "damnable alternating current."

He evidently has not had the least experience with the alternating current as applied to electric lighting, and his information seems to have been derived chiefly from a gratuitously circulated publication of the corporation, the sale of whose particular apparatus is most affected by the alternating system.

In spite of all that has been said on this subject in the past year at the various electrical conventions, in spite of the published descriptions of the various converters manufactured by different companies, without taking the trouble to inform himself by actual inspection of a single converter, he again repeats the statement which I can characterize as nothing but the grossest ignorance of electrical manufacture, or a deliberate falsehood, that between the two circuits in a converter "is interposed nothing more than a thin layer of cotton or silk insulation," and he says "that as has happened again and again, it requires but a flash of lightning or a little moisture in the converting apparatus to bring the "death current" to each lamp," showing his utter ignorance of the whole subject, not to know that in the first place only the lamps of one group would be affected, and they would only be affected by being extinguished, for in such cases the safety fuses would instantly melt and cut off the current. A more contemptible evasion of the real question at issue I have never seen than his reference to Messrs. Siemens and Halske, as opponents of the alternating system. Messrs. Siemens and Halske abandoned the manufacture of alternating current apparatus for the same reason that Westinghouse abandoned their apparatus after having tried it, namely, because they could not make commercially efficient apparatus which would not overheat and burn up, and the fact is that Siemens and Halske are to-day making and selling the underground cables for alternating current work in Europe. These cables have one conductor in the centre surrounded by an insulating material; the other conductor is wound on the outside of this with a second layer of insulating material, and the whole is then covered with a sheathing of steel tape, and Messrs. Siemens and Halske recommend and guarantee these cables for use with an alternating current of 5000 volts.

He says that he does not know of a single disinterested electrician of high standing who does not condemn the alternating current system. His acquaintance with eminent electricians must be limited. Why did the Edison company secure the control of the Zipernowski system as soon as the Westinghouse had made a market for the alternating current in this country? Why did the United States company secure the Jablochkoff system for the same purpose? Are not Ferranti, E. J. Houston, Elihu Thompson, men of high standing? Truly, these men are all interested; but who are disinterested electricians nowadays? Professor Forbes, of England, is usually referred to as probably one of the best posted men and the most thoroughly disinterested electrician of the day, and I, myself, heard him say at the electric light convention, held last February in Pittsburgh, that the alternating system as installed in America, made him feel that we were far ahead of anything they had done in England, and that he had completely changed his opinion, and was now satisfied that the alternating system was safer than any direct current of the same tension could be. For people who have absolutely no experience with electric lighting by alternating currents to refer to speeches made five years ago by electricians, however eminent, is folly, when we recall the history of the alternating system in this country. First, it was an impossibility. Then this was limited to its being a commercial impossibility, and when its adoption showed that it was a success, every pettifogging self-styled electrician, who had been engaged in proving it ridiculous, turned his attention to proving that it was old, and that everybody knew about it years ago, and the very companies, who had been ridiculing it, both publicly and privately, turned their attention to foisting on the public the most unblushing and slavish imitations of the successful form of this apparatus, which is meeting such success in this country, and which has excited the unqualified admiration of European electricians.

Now the fact is that it has been proved in a dozen cases that the alternating current, while disagreeable, is less dangerous to life than a direct current of the same tension. Personally I have received the full 1,000 volt current from an alternating current machine, not once, but half a dozen times, and I have received the direct current in the same way, and, while the direct current will always make one sick for some time after the shock, the alternating current leaves no such effects. I have seen five or six men get this 1,000 volt alternating current shock direct from the machines. I have pulled one off who was hanging to the bare switch-board wires and whose hands were badly burned, but who in half an hour was at work again, having in the meantime walked by himself to a doctor to have his burns dressed. Add to this that this high tension current is thoroughly insulated and protected from the house circuits by layer after layer of insulating tape, mica, fibre, and by an open air space, and one can easily see that the danger of high tension reaching the house is very remote indeed.

Mr. Brown has chosen to exhibit his ignorance and bias by speaking of lightning bringing the high tension into the house; that is to say, the lightning to enter any one house by the alternating current wires, has to break down the whole insulation of the converter, while the direct metallic connection on the system which Mr. Brown is pleased to favor brings the lightning itself, with its tens of thousands of volts, direct to every lamp on the system, without the slightest check or hindrance. Yet how many people have been killed by lightning coming in on such wires? No one that I have ever heard of, and Mr. Brown knows that this danger is infinitesimal, or he is merely truckling to the prejudice in favor of direct current systems, when he makes any such statement.

He spoke of the Chicago board having forbidden the use of the "fatal alternating current." I presume he means the same board whose inspector read a paper before the Chicago Electric Club, in which he showed the induced discharge from a simple magnet as an instance of an alternating current. They will simply have to abandon this position. Would it not be a good deal more sensible to follow the example of the Philadelphia board, which has simply placed the very strictest regulations (and what is a different thing, enforces them) as to the use of not merely alternating current apparatus but of all apparatus, and came to this conclusion after a thorough inspection and test of the insulation and general construction of the alternating current converters.

When Mr. Brown styles himself "An Electrical Engineer" he lays himself open to the pertinent inquiry, What has been his experience? What was his education on the subject? With what companies has he been engaged? What work has he done to which he can point with pride as a specimen of careful work? Is not this the same Mr. Brown of the "Brown Converter," who endeavored strenuously for two or three years to convince the various arc light companies of the country that it would be a great benefit to the public at large and to their dividends (for which he now expresses such a lordly contempt) to carry a 3,000 volt current for incandescent lighting into houses and stores by means of an apparatus of his own devising, and which was designed to occupy the very field now taken by the alternating current system? It is curious that he should apply to the alternating current system the very expression which was applied to it by one of the salesmen who was trying to induce me to adopt the "Brown Converter" for house lighting on arc circuits, that "this damnable" alternating current system was just "wiping out apparatus" like theirs "all over the country." Can it be possible that a distinguished electrical engineer, like Mr. Brown, could allow himself to be swayed by any such trifle as this? Let us trust not. Yours, truly,

T. CARPENTER SMITH.

THE HONORABLE, THE BOARD OF ELECTRICAL CONTROL.

Gentlemen:—In the New York *Evening Post*, of June 5th, there appeared an article by one Harold P. Brown, electrical engineer, upon the dangers to be expected from electric lighting apparatus. This I have read, and carefully noted his suggestions to your board regarding certain precautions which he claims should be observed. It appears to me that the article is hardly written in a fair spirit, and that many of the comparisons are obviously unjust and incorrect, and the suggestions impracticable.

In the first place the current from open coil armatures is referred to as "pulsating" and "death dealing" and is described as being much more fatal to human life than the current from a dynamo having a closed coil armature. It seems to me that this is purely and simply a matter of conjecture on the part of Mr. Brown.

I have tried many times to distinguish between the physiological effects of this so-called pulsating current and those caused from a closed armature. I have used in all cases sufficient resistance in the main line to give a difference of potential of from 60 to 200 volts. The sensation experienced in each case is precisely the same as is the effect upon the needle of a delicate galvanometer, which will stand perfectly still when under the influence of a current of either character from a properly constructed machine. No doubt but a voltage of 2,500 *would fatally* injure any person introduced into the circuit, but the idea that the effect of the open coil armature current would be many times that of the closed coil would be merely guess work, for I do not consider we have any reliable data to work from.

Assuming there have been more unfortunate accidents upon circuits operated by dynamos of the open coil class, what do they prove? It is well known that these dynamos can carry more lights and consequently a higher potential than the other style, and who

can say that Mr. A. and Mr. B. would have lived had a shock of the same voltage come from a dynamo of another type. One thing is certain, viz.: that there have been fewer fatalities resulting from the electrical current than from steam or other motive power. It is stated that but five men have been killed in New York during the past 10 years.

Mr. Brown compares the alternating current as produced by dynamos, with that emanating from what is generally known as the medical coil. He, as an electrical engineer should know that they are in no manner similar except that they both are bi-direction currents. In the first place the current of the ordinary medical coil capable of throwing a spark one-sixteenth of an inch in length, is immensely greater in pressure than that of the 1,000 volt generators now in use which are incapable of striking through an air space of even one-hundredth of an inch; and again, the current in a medical coil is produced by a direct current being made and broken, inducing currents of tremendous pressure—of but little volume in the secondary. The unpleasant feeling caused by this current is directly traceable to what is known as the extra current, caused by the rapid changes in quality of the magnetization of a core of iron upon which the coil is wound as well as the self-inductive effect of the coil itself.

With the alternating current the case is materially changed. A very small amount of wire is revolved in the field of force which is absolutely constant and is not affected in the least by changes in the external circuit. The amount of potential is predetermined and controllable. There is no self-induction of any moment, to produce the dreaded extra current; and opening the circuit or introducing one's self into it, merely subjects one to the pressure of 1,000 volts which has never yet proved fatal. There is no extra current and no kick from the field magnets.

But in supplying incandescent lights from alternating current circuits, it is not customary, for many reasons, to introduce the high pressure wires into the interior of the buildings. Between the primary circuit and the house circuit a transformer is interposed which effectually changes the character of the current from one of 1,000 volts pressure to one operating but 50 volts.

Mr. Brown states that there is but a thin film of cotton or silk between the primary and the secondary windings of the transformer, and that this is liable at any time to be ruptured by a flash of lightning. This shows that he is totally ignorant of the construction of alternating current apparatus as well as the method of installation adopted by the leading persons in the business.

I am familiar with various methods of protection used, and have no hesitation in stating that when such as I shall describe, which have been adopted by the Thomson-Houston Electric Co. are carried out, there is no possibility of a high potential affecting persons through any accidental contact with the secondary wires. In the first place, this company operates its dynamos at a potential of but 1,000 volts, as against 1,800 or 2,500 used, and, so far, with safety for the past two years in many places abroad. For every installation of transformers a lightning arrester is used which is absolute in its action and effectually prevents any ill effects to the transformer from a lightning stroke upon the line. I have never known one to fail yet. Then the primary winding is separated from the secondary by a very substantial section of insulating material thoroughly dried and shellaced, and finally, the secondary or interior circuit is soundly connected to the earth. Where is there any danger now? Even if the high potential were to get upon the secondary line, what possible harm could be done? Suppose the primary line in a first-class condition and the secondary properly grounded as described; also the accidental contact upon the primary and secondary. A person touching the secondary, and at the same time making contact with the earth, would be affected in what manner? Not at all. Why? Because there is no complete circuit. But go further, and suppose a ground upon the primary as well. A person touches the secondary and again there is no effect. Why? Because there is a complete shunt about his body caused by the earth and the ground connections, and even if the transformer were not instantly cut out of the circuit, all the current would go by a shunt which is of no resistance and would not influence the man at all. Why should Mr. Brown be so set against the high tension alternate current when it has been in successful operation for so long a time, and which even under the worst conditions could but introduce a potential of 1,000 volts upon a few lamps at a time? It is not consistent, because we find about a year ago a description of "The Brown Automatic Converter," a modification of a device to be used in running incandescent lights from arc current circuits "without involving a large expense for incandescent lighting plants, or the necessity of getting a large number of subscribers to commence with; and also valuable to incandescent lighting companies for customers too distant for the ordinary incandescent circuits."

Why are no charges made here against incandescent circuits, which must be considered extraordinary? Surely no man so careful for the safety of a general public would advise the use of such an arrangement which is liable at any time to bring a difference of potential as high as 3,000 volts into a man's house, and this pressure too of a dynamo producing a "deadly pulsating" current, for we read in the advertisement in capitals "CAN BE USED WITH ANY MAKE OF ARC LIGHT DYNAMO." To say the least it looks very curious, and one is inclined to read between the lines when noting an "electrical engineer" stand forth in condemnation of the one successful, commercial method of introducing the electric incandescent light and stating that the use of 300 volts of alternating current is dangerous, but implying that the operation of incandescent lights upon 3,000 volt current circuits is not to be condemned when in conjunction with the converter. Let us take up his letter again and turn to the suggestions.

In order to discover the presence of grounds upon the line he advises the use of a permanent ground connection at the station.

Inquire among station superintendents and see how many of them agree with him. In order to keep a line in condition we are told to subject it to a constant strain at every insulator and contact point. Is this wiser than the present method pursued by all properly governed companies? viz.: To test the circuits every day and to keep them free from grounds. Also to shut down should any vicious connection occur during the night. There is a station in this city which is constructed on sound principles. The wires are well insulated and well run, and there has not been a ground on a circuit for weeks.

Again we are told that to prevent the flow of the extra current through the body of a person introduced into the circuit, we are to place a voltmeter or high resistance about the dynamo terminals. Very well, do so and what will you have? Evidently the resistance must be high in order that too much current may not be going to waste; now will not the "death stroke" divide itself according to the law of shunts, and will not the person get a good share? If the resistances were constructed as a coil I am not sure but its effects would be practically useless, and until it is definitely known whether it is the prime potential or the after current which kills we had better pay more attention to the exterior lines and construction and less to such traps.

And again we are to provide a means for automatically shunting the fields when the external circuit is opened. There is more merit in this than in the other schemes; but I do not believe any device could be made sufficiently sensitive to operate in time to prevent any person opening the circuit, and at the same time not to interfere at improper moments.

As there are so many simple and effective methods for determining when the circuit is broken, it does not seem wise to make any such law.

The reference to the Siemens company is not bad. It has been published in several papers in New York and Boston and always in the same words. Investigation shows that the company referred to never did make a business of manufacturing alternating apparatus other than a dynamo, which is to-day made by them and for sale in Europe. Perhaps the reasons they did not manufacture can be found in the records of the patent office, or may be Rankin Kennedy's articles on alternating current apparatus would prove of assistance to those desiring a partial idea of the true state of affairs abroad. The position of Chicago and its inspector is well known.

We read last that the "damnable" alternating current should not be permitted in higher voltage than 300, and that if the proposed rules are adopted three men shall not have died in vain. It can only be said that most of the rules, as well as the letter, show under a philanthropic exterior a distinct bias; which perhaps may be accounted for when we recall Mr. Brown's connection with the American company whose dynamo has a closed coil armature. It would be interesting to read the opinions expressed by Mr. Brown when he was engaged in installing the plant of the Brush open coil system in Eau Claire, Wis.

A summary of Mr. Brown's paper may be made as follows :—

First.—The alleged comparison between the effects from a medical or Galvano-Faradaic coil and the alternating current dynamo does not exist.

Second.—The death dealing quality of the current from dynamos having open coil armatures is but conjecture.

Third.—Placing a shunt of high resistance about the terminals of the dynamo is impracticable, and would but partially compensate for the after or extra current.

Fourth.—It is not clear that death is caused by the after-current or "kick" of the machine. In fact it is probable that such extra current is not essential, from the fact that fatality has occurred from simple connection with a grounded wire.

Fifth.—A constant ground on a high tension dynamo in order to detect a second one is poor engineering.

Sixth.—A break in the circuit would be indicated by the performance of the apparatus in the station, and the one in charge should shut down without any further notice from a complicated device which might render steady commercial service questionable.

Seventh.—Under no circumstances should 300 volts be made the limit allowed alternating current service, because practical demonstration, extending over a period of two years, shows that where the proper protecting devices are used there is no danger.

In conclusion, the writer must suggest that in the action already taken by your board regarding overhead construction, is to be found the solution of the danger question.

Of course the electric current under certain conditions is dangerous, but no more so than steam plants or various forms of

motive power. What is needed is *control* and not *prohibition*. Look over the lines last constructed in your city, and note that any danger from them must be preceded by some accident not traceable to the installation or operation of the plant. A stone upon a rail may wreck a train. A boiler under 150 lbs. steam is subjected to greater strain than one with 50 lbs., but by strengthening the construction we keep the steam in. Follow rule No 2, suggested by Mr. Brown, and let us use better insulated wire. Whether it be Cowles' or Simplex, Trinidad or Bishop's makes little difference, but keep up the standard. The extra first cost of an installation even with the most expensive wire will not average more than five per cent. on the total investment, while the percentage improvement in dividend paying quality is not to be estimated. Respectfully submitted, S. C. PECK.

New York, July 12, 1888.

FORT WAYNE "JENNEY" ELECTRIC LIGHT CO.
FORT WAYNE, IND., June 29, 1888.

THE HONORABLE BOARD OF ELECTRICAL CONTROL,
New York city, N. Y.

Gentlemen:—The question of the danger of alternating currents in the present systems of lighting by incandescent lamps has been in the past a much-discussed one, both at the meetings of the National Electric Light Association as well as at the meetings of various scientific societies throughout the country, and the conclusions arrived at by those who are theoretically and practically competent to judge are that the alternating current is not dangerous by any means when used within certain limits of pressure and that the safety limit approximates 1100 volts electromotive force. After an extended practical experience of three years by those who have carefully followed the alternating systems in use, and after many physiological experiments, frequently involuntary ones, to determine the safe limit of pressure to work with, it has been found that no fatality can occur or serious inconvenience result from a shock from an alternating current having a pressure of that already cited, 1100 volts. It has been long and well known that in most cases where fatal accidents have happened with high tension continuous current systems, the death shock is received at the moment of breaking away from the circuit, not at the moment of completing the circuit around the body, the reason is obvious and two-fold, *viz.:* When you place yourself in a circuit in which there is flowing current at a dangerous pressure, the skin of the body, which has a very poor conductivity, in fact has good insulating properties, partly protects you from the danger shock, but as you will involuntarily make a desperate attempt to throw yourself out of circuit and succeed, at the moment of breaking away an arc will be set up, burning the body insulation (the skin), and freely entering the trunk cause paralysis of the respiratory organs, preventing thereby the blood from being oxidized. Death will then ensue unless instant remedies be applied, and right in the latter line, recently in France, the passage of an alternating current through the body has been very efficacious in restoring life. The other reason of the fatality referred to is, at the moment of breaking circuit, an electromotive force, far higher than was normally in the circuit, is developed, considerably aggravating the effect of the shock.

In an alternating current of the same dangerous pressure there will always be a much better chance of escaping a fatality than in the case just quoted, as in the first place the electrical impulses being equal and opposite, the effect of the normal electromotive force alone will be experienced, for at the moment of breaking away from the circuit when the pressure would have a tendency to rise, an impulse in the opposite direction, will instantly neutralize it, and the E. M. F. is maintained normal; again, the very nature of the current with the impulses equal and opposite also tends to suppress the arc at the moment of breaking, for the self-same reason as that which tends to maintain the E. M. F. normal, preventing the skin from being so badly burnt, and the current proportionately from free and dangerous passage to the vital organs.

The danger attending the use of converters has been referred to, chiefly, however, by those not familiar with their construction. We will admit for the sake of argument, that we have exceeded the safe limit of pressure in the converter, and let us see whether the dangerous current will or will not reach the users of the incandescent lamps.

I will premise what I shall say at this point by stating, and I have occasion to say so elsewhere, that two-thirds the difficulty is overcome when you understand its nature. Now in this case we want to prevent the dangerous current reaching the users of lamps, we know the current is dangerous, our practical experience has so informed us. The secondary coil in the circuit on which the incandescent lamps are placed is in the same iron receptacle as the dangerous primary coil which is connected with the primary circuit, and by the entrance of moisture or a discharge of lightning the organic insulation between the two coils might very readily give way, as it occasionally did in the earlier experimental stages of the work years ago; we should not, however, trust to any insulation to keep the current in the respective coils; in this case we simply introduce a conducting strip of copper or other metal between the primary and secondary coils in the box containing the converter, this strip being carefully insulated from both primary and secondary coils, as may be seen in the converter submitted for inspection.

Now what is the effect of the dangerous primary current, endeavoring to reach the secondary coil and circuit? It will be obvious that it will be intercepted by the interposed metallic strip referred to, and the current which might enter the secondary is diverted to a ground connection made with this strip. Should a lightning discharge enter the primary, it will surely go to ground, for which it has in all cases an affinity, seeking the passage of lowest resistance. Should a lightning discharge strike the house and the secondary circuit, and make an attempt to get on the line through the primary, again it is intercepted by the metallic strip and the integrity of the insulation between the primary and the secondary is maintained, no harm happening.

These precautions have been dictated by experience in the induction apparatus; and I may be forgiven when I say that any other difficulty which may present itself as time rolls on and the alternating systems develop in magnitude, will be equally carefully and successfully met.

As an instance of the unmeaning glibness of the speech of some of those who desire to constitute themselves authority on the subject, but who have never qualified in any practical form, speaking of the dangers attending the use of the alternating current, in the New York *Evening Post* of June 5, a gentleman states that the danger attending the use of alternating currents will not be decreased, but contrarily will be greatly increased by placing the conductors underground. It is evident that the gentleman has concluded that because with the underground low tension continuous system, great difficulty has been experienced in properly insulating to prevent troublesome grounds and disastrous leakages, that all other systems as a matter of course suffer similarly. In point of fact the low tension current at 220 volts in underground conductors offers a far greater strain upon insulation than a high tension alternating current at 1100 volts. It will be known that one of the functions of a current flowing through a conductor is a heating one, that the greater the current transmitted through a given conductor the greater the heat, or in other words, the heat developed is as the current squared into the resistance, $C^2 \times R$. It will further be known that with slow radiation, as must necessarily be the case with the conductors underground, the heating effect with a given current and cross-section of wire must be enormously increased. With low tension continuous current systems it frequently happens during the hours of heaviest lighting that a loss of some 20 to 25 per cent. is incurred in the conductors, and any person familiar with the temperature that a conductor attains at such a loss as this will not wonder at the trouble of the low tension system and the consequent strain on the insulation. On the other hand with the alternating current no such loss in the conductors need ever be permitted; throughout the hours of use it may, therefore, be comparatively cool, certainly never warm enough to prejudicially affect the insulation. The reason of being able to work at a low temperature in the latter case, of course, is that working with a current alternating in polarity, small in quantity and high in tension, we can afford to work at a much less waste of energy and corresponding reduction of temperature in the conductors; therefore, the insulation of the wires in the latter case need never be strained, the strain on the insulation by the use of the higher E. M. F. being more apparent than real. These conclusions have been arrived at by careful practical experiments that no amount of sophistical theorizing can refute, and are equally within the scope of all who wish to familiarize themselves with a few elementary facts.

By the use of the alternating current as now employed by companies long in the field, who have a reputation at stake, the electrical engineer has placed in his hands an electrical lever, so to speak, with which he may move the world, practically the greatest of all electrical developments of the age, of incalculable value and far reaching possibilities, and any objections to its use (and their name will be legion) by interested persons should be regarded and dealt with carefully and impartially as affecting something of immense public value as well as something of future public value that at present it is impossible to overestimate, and should not be too hastily condemned in consequence, by the utterances of the inexperienced.

Yours very truly, MARMADUKE M. M. SLATTERY.

OFFICE OF
RALPH W. POPE, Consulting Electrical Engineer,
No. 30 Temple Court,
NEW YORK CITY, July 9th, 1888.

Hon. THEODORE MOSS,
Secretary, Board of Electrical Control,
New York city.

Dear Sir:—I have the honor to acknowledge the receipt of a copy of the minutes of the proceedings of the Board, dated June 8th, containing a resolution in which my opinion is requested, regarding certain suggestions as to the amendment of the rules

of the Board, proposed through the public press by Mr. Harold P. Brown, which are as follows :—

RULES FOR STATION LIGHTING.

(1) Not more than 50 arc lights shall be operated upon any one circuit, unless said circuit is used exclusively for street lamps mounted upon wooden poles; in this case the number shall not exceed 60.

(2) All out-door arc light circuits must be provided with waterproof covering, having an insulation resistance of not less than one-half a megohm. Any circuit falling below this must not be used until restored.

(3) No arc light dynamo shall be operated unless provided with a voltmeter across its terminals, or other device, to provide a path for the extra current caused by the opening of the external circuit.

(4) No arc light dynamo shall be operated unless provided with means for automatically stopping the production of current the instant a ground connection is made upon its circuit.

(5) No arc light dynamo shall be operated unless provided with a means for automatically breaking or short circuiting the field circuit the instant the external circuit is broken, in order to prevent a current from being built up by the broken circuit ends falling upon some conductor.

(6) No alternating current with a higher electromotive force than 300 volts shall be used.

I have also read the communication of Mr. Brown accompanying the proposed amendments. It has been my privilege to attend a large proportion of the meetings of the Board, and I believe I thoroughly understand its desires in the premises, which are in the main, to bring about a reform in the existing condition of electrical conductors in this city, without interfering with the business interests of their owners or depriving our citizens of the many benefits accruing from the various systems which depend upon electricity for their successful operation.

One of the greatest difficulties encountered in the proper regulation of electrical service prevails in other branches of modern industry, where the danger to life is outweighed by the desire to increase financial gain. These facts are so generally recognized that I refer to them merely as a reason why it is proper that every precaution which science can devise should be utilized for the protection of human life. The rules in question appear to have been framed with this object in view, and so far as they are confined to this praiseworthy object, they meet with my unqualified approval.

It is now the generally accepted opinion among scientific investigators, many of whom have had ample experience upon which to base their reasoning, that there is a wide range of difference between various persons as to their power of enduring the effect of an electric shock. The same person may also be much more susceptible to its influence under certain conditions of the body, as, for instance, when the skin is moist from any cause. A person unaccustomed to the peculiar sensations caused by the passage through his system of an electric current, if of a sensitive nature may suffer from fright. Indeed the mere spectacle of a thunderstorm, where the chances of personal injuries from lightning are infinitesimal, may produce serious results. It will therefore be understood that it is extremely difficult, if not impossible, to fix upon an arbitrary standard which an electric current must not be permitted to exceed; for the reason that many useful classes of service may thus be entirely prohibited without any substantial reason. All forms of electricity as used in the various systems with which we are familiar, are entirely controllable, with the exercise of such skill and experience as now exist. No form of current is used which, with the exercise of proper precautions, cannot be confined to its legitimate path, and it is in this direction that it appears to me our efforts should be directed. When, with the introduction of every known precaution, it is found impossible to so confine an electric current to its proper channel, it will be time enough to prohibit it by statute. The very fact that many companies now doing business have *not* exercised that precaution which the interests of the public demand is the reason for the existence of the Board of Electrical Control. In view of the prevailing opinion upon the importance of so constructing and operating an electrical plant of any description, it appears to me that any company or individual proposing to establish an industry of this character, at this date, must be well aware of the importance of complying with such rules as are established by the proper authorities acting in the interests of the public.

The pith of the line of policy to be pursued, in my opinion, therefore, would be not to fix upon any particular number of lamps to be operated on one circuit, or any standard of voltage which must not be exceeded, but rather to insist on such methods of construction and the use of such material, that the current will be confined to its designated conductor. This implies the use of a conductor of ample size for the current to be used, and properly insulated at all points, the insulation resistance increasing in a proper ratio to the increase of voltage.

If we aim constantly in this direction, I believe we shall eventually attain the end we all have in view, which is the greatest possible extension of the benefits to be derived from the more general use of electrical devices, without danger either to life or property, even when the various fixtures and appurtenances are necessarily within the reach of persons not familiar by training with the mysterious dangers which are supposed to lurk in every electric wire.

I would, therefore, respectfully suggest that the first and the last of the proposed rules be stricken out, and that the second rule be more fully elaborated.

In view of the fact that with the best possible methods of construction accidents are liable to happen, rendering an otherwise perfect system defective, I should recommend the adoption of the precautionary rules numbers 3, 4 and 5, provided there be no existing practical reasons why they should not be enforced, as I am not in favor of the adoption of any regulations of such a character that they must necessarily remain a dead letter.

Yours very truly,

RALPH W. POPE.

STEVENS INSTITUTE OF TECHNOLOGY.
HOBOKEN, N. J., July 16, 1888.

THE BOARD OF ELECTRICAL CONTROL.

Gentlemen:—In response to a letter from Mr. Theodore Moss, dated June 20, inviting me to express my views on the subject discussed by Mr. H. P. Brown in a letter to the *Evening Post* bearing date June 5th, 1888, I would say that I quite agree with Mr. Brown in his opinion that in all cases mentioned by him in which death has been caused by coming in contact with electric wires the accidents would have occurred, just the same, if the wires had been buried underground, or, to use his own words, "I know that burying the wires would not remedy the trouble." I would, however, go further than this and say that in the instances he cites and in all others known to me, the accident which occurred would have been more likely to occur or more certainly fatal if the wires had been buried underground in any arrangement which has as yet been provided for that purpose, and this chiefly for the following reasons :—

The buried wires, as experience has abundantly shown, are in constant danger of making earth connections which render a contact with only one point fatal where it would be otherwise harmless. Even the Edison wires in New York are frequently being torn up to repair injuries due to loss of insulation, notwithstanding their very low electromotive force, of but 110 volts, as any one can see who has occasion to go about the streets traversed by the Edison conductors down town.

When currents of 20 times this "electric pressure," as it has been aptly called, are used this tendency to rupture the insulation is proportionately increased and has proved practically fatal to any commercial success in using such currents through underground conductors.

Those persons who have been killed by touching lamps or single wires have been killed only because there was some earth connection already established elsewhere on the circuit.

Again in the instances where employés of the electric companies have been killed while employed in connecting or otherwise working with wires carrying currents, it is manifest to any one that the danger would be greatly enhanced if their work was to be done in dark and narrow "man-holes" in place of in broad daylight and in free space.

The cry of the public as represented by the daily press, to put the wires underground as a remedy to all dangers and difficulties, is not an intelligent cry, but, on the contrary, is the result of ignorance and misdirected prejudice.

In the next place Mr. Brown points out at some length the difference between a continuous uniform and a pulsating or alternating current, but in this connection I think that he has rather mixed up and confused several different things.

The intense effects produced by an induction coil such as is used for giving shocks and in medical treatment, is not the result of its interrupted character, but of the peculiar arrangement of magnetic core and coils of wire, by which the electromotive force of the interrupted secondary current produced is raised to a point fully equal to that of the longest circuit ever employed in an arc light system.

In other words, the *electric pressure* obtained in a medical coil is fully equal to that in an arc light circuit carrying 50 lights. It is also alternating, and therefore, as far as their conditions are concerned, should be certainly fatal. Such, however, as every one knows, is not the case. I myself once received the discharge of such a coil capable of giving sparks 21 *inches long*, and therefore equal in electric pressure to hundreds of arc light dynamos united for that purpose, and the sensation was no worse than the shock from a Leyden jar of moderate size.

It is manifest, therefore, that the interrupted or alternating character of the current even when combined with the highest electric pressure, is not its essentially fatal condition.

The actual facts seem to be these, as far as we can gather from the fortunately very limited number of accidents, fatal or otherwise, which have occurred.

There are two ways in which the electric current can derange the living structure,—1, by mechanical and chemical injury to the organic structure; 2, by nervous exhaustion or nervous shock.

The first of these requires the passage of a considerable volume of current with enough electromotive force to carry it through the resistance of the body. These conditions are fulfilled by a continuous or uniform current of high electromotive force, and are not found in the same degree in an alternating or interrupted current.

The second method of injury, or that by nervous shock, requires chiefly the interruption or reversal of the current, but this nervous influence only becomes dangerous when long continued or combined with the other influence of large current volume.

Experience, however, shows that the interrupted current loses as much in the direction of fatal effect from organic destruction as it gains from its superior nerve exhausting power, so that quite as many have escaped without fatal consequences from an alternating current as from a continuous one. Either may be fatal, but neither has any known superiority over the other in this respect, and there is certainly nothing in the results of experience or observation so far which would warrant us in requiring less precaution in the use of one sort of current as compared with the other, or in excluding one where the other was admitted.

Mr. Brown states, as of his own knowledge, "scores killed and maimed by the pulsating currents." In regard to this I can only say that I have no such information either direct or derived and would be very much interested in investigating these scores of cases, if Mr. Brown would give some specific reference to them.

I quite agree with Mr. Brown as to the imperfections of the underwriter's wire. This wire was passed or allowed by the underwriters many years since, when it was the best and only wire available for the purpose; but they have since "approved" many other wires with superior insulation which have just as much claim to be called "underwriter's wire" as the first and inferior kind.

What Mr. Brown says about the universal condemnation of the alternating system by electricians of high standing and disinterested, must be founded upon a very limited knowledge of the subject. The only authority he cites is that of Siemens and Halske, who are known to everybody as manufacturers of, and dealers in, dynamos, electric lamps, etc., patented by themselves, and authors of a pamphlet or trades circular attacking the rival system of electric lighting by secondary currents with so manifest a bias, as to deprive what they say of any weight whatever. I can hardly believe that Mr. Brown can have seen this publication, but must speak from some incorrect report of its contents.

Without taking up more of your time, however, with a discussion of Mr. Brown's preamble, I will at once pass to his proposed rule.

Rule 1, proposes limiting arc circuits to 50 or 60 lamps each. This would be a very unscientific and unfair method, as it would allow some companies to run circuits of twice the electromotive force or pressure of others. Thus 50 Brush lamps would require an electromotive force of 2,500 volts, while 50 U. S. Electric Lighting Co's lamps would require but 1,500 volts. The rule should be founded on some accurate standard of measurement, and be not like the weight standards of the early Dutch settlers described in Knickerbocker.

Rule 2, providing for insulation of wires as stated, is utterly indefinite and meaningless. Under it a naked copper wire might comply with the requirements and the Atlantic cable might fail to do both, within reasonable constructions of the rule as stated.

Rule 3, providing for a cross-circuit of high resistance near the dynamos, is also indefinite and unnecessary, but would do no harm.

Rules 4 and 5, providing automatic means of shutting off dynamos on the grounding or breaking of their circuits, are good; but are already carried out in most electric lighting systems.

Rule 6, excluding the use of alternating currents of high electromotive force, is unwarranted and absurd.

If more time was at my disposal I could enlighten your commission on many other points connected with this subject, but believe that I have said enough already to discharge my duty as a good citizen in a matter in which I have no direct concern.

Very truly yours, HENRY MORTON,
President.

PITTSBURGH, PA., July 7, 1888.

C H. JACKSON, ESQ.,
Pres. Safety Electric Light and Power Co.,
New York city.

Dear Sir:—In reference to the questions which you have brought up for my consideration regarding the safety and reliability of the alternating current system of distribution, I would say first, in regard to the matter of personal safety, that I regard the alternating current less dangerous to human life than the direct current, for several reasons. In the first place, I am well acquainted with a number of electricians and men connected with electric lighting work who have received, through their bodies, a current due to alternating difference of potential, varying between 1,000 and 2,000 volts. I have myself received 1,000 volts without even temporary inconvenience, and in the case of one of the electricians connected with our interests, a shock of something greater than 2,000 volts was received without fatal results. During my experience with direct current dynamos I have frequently received a shock due to the extra current from the field of a machine suddenly opened, and I have no hesitation in saying that the shocks I have received in this way from machines designed to produce only 100 volts electromotive force, were much more severe than those I have received by direct contact with the primary circuit of a Westinghouse 1,000 volt dynamo, when its field was charged to the full normal amount.

It is simply out of the question to produce any practicable extra current in the armature circuit of an alternating current machine from the opening of the field, particularly when the machines are separately excited, and this is for the reason that there is no connection between the armature and the field circuits, and the effect of suddenly interrupting the field current is only to interrupt the current in the armature without producing a sudden flash of high electromotive force, which inevitably follows from the interruption of the field of a direct current machine. The construction of the alternating current dynamo is such that, although the current changes its direction 200 or 300 times a second, yet it is prevented by the very nature of the machine from raising any potential beyond a certain limit determined by the design of the machine. In the direct current machine, on the contrary, there are no such restrictions, and I feel quite safe in saying that the discharge from the field of a direct current machine of 100 volts, normal potential, may be capable of rising to fully 100 volts when the field circuit is suddenly interrupted. I do not give this as a matter of opinion solely, but as a matter of actual experience and conviction. This quality of the direct current machine has often rendered it necessary, in my own experience, to interpose a number of incandescent lamps, say five or six, across the breaking points of the field rheostat, so that on the interruption of the field circuit the arc formed across those contacts would be prevented to some extent, the result of this arrangement is that half a dozen or more lamps, connected in series, would be flashed up to their full brilliancy by the so-called 100 volt dynamo; whereas, under normal conditions, it would require as many 100 volts as there are lamps to produce a similar condition. There is a very convincing reason for the small danger due to alternating current shocks to the human body as compared to those received from the direct current; namely, the fact that the conducting fluids are more or less decomposed or electrolyzed by the passage of the direct current, while it is well understood that such an effect is not produced by the alternating current. It is therefore evident that the passage of the direct current through the human body, for even a moderate length of time, may be sufficient to so decompose the fluids and tissues of the vital parts as to produce fatal results very quickly; whereas a current of the same quantity of rapidly alternating potential may produce only a shock to the nerves without any organic change, consequently without permanent or even serious danger.

This statement is well borne up by the fact that it is impossible to measure correctly the resistance of the human body by means of a direct current, as the resistance changes continually while the measurement is in progress, even where the contacts are preserved carefully, and where the utmost care is exercised to produce accurate results. The decomposition of the fluids thoroughly explains this, since it is a well-known fact that in all cases of electrolytic action the resistance is never the same for any considerable period. With the alternating current system it is possible to obtain definitely the resistance of the human body with contacts of a given nature; consequently, the effects of the alternating current can be determined and counted upon much more easily than the direct.

Laying aside the question of the relative danger of the alternating and direct current, it is a matter of every-day experience that a 50 or 100 alternating current is perfectly safe; and it is perfectly possible and easy to confine the difference of potential entering a house from the street circuit.

The insulation on the converters as now employed, and as they have been in use since the commercial operation of the alternating current system is so perfect that among several thousand converters now in use under the patents of the Westinghouse company, I have yet to learn of a single instance in which any connection has been discovered between the primary and secondary wires. These converters have been in use under almost every conceivable condition of location, and surrounding conditions, and a large number of them being in use in the open air, and up to the present time no accident to life or property has been recorded. As a matter of fact the converter is a safeguard to the consumer, protecting him from all dangerous currents likely to traverse his wires, namely that from lightning. Where the circuit is continuous from the pole line to the lamps an excellent conductor is provided for the discharge of the lightning flash wherever the ground insulation happens to be the weakest, and for this reason we hear of lightning entering buildings and destroying property to a greater or less extent, particularly at the central stations where the greatest number of conducting wires

enter, and where masses of metal, either more or less connected, are apt to form the weakest points in the system of insulation. Where the converter is interposed between the line wires and the circuit likely to be handled by the consumer, a safeguard is provided, the effect of which on the passage of a lightning discharge is simply to work an injury on the converter itself, separating it from the surface wires, and temporarily interrupting the supply of current. In the experience of our company a number of cases have occurred in which lightning has almost totally destroyed the converters, and the result has been in every case to disable the primary coil, cutting it out of action and immediately freeing this circuit from the converter, owing to the increased current passing through the primary coil under these conditions. It will be impossible for the converter to remain in circuit when sufficiently injured by lightning to render insulation between the primary and secondary circuits insecure. Under all other conditions than the burning out of the converter by lightning or destruction by fire, the nature of the insulation between the primary and secondary circuit is so perfect that it is almost impossible that any connection should occur between them, since the insulation is made up of several distinct and perfect envelopes for the wire. These insulations are as waterproof as it is possible to produce them, when uninjured by a mechanical abrasion, and from the latter the coils are thoroughly protected by an enclosure in the iron casting with which each converter is provided. The insulation is not only carefully carried out from the primary to the secondary coil, but between each coil and the iron plates which form the surrounding field; so that the insulation measured from one coil to the other through the iron is in reality double the insulation from coil to coil.

In regard to the question that has been raised as to the reliability of the safety fuses, I would simply call attention to the well-known fact that the fuses of moderate size are much more quick and reliable in their action than the large fuses. The current in our system traverses four pairs of fuses between the dynamo and the lamp, all of which fuses are of moderate size, even where 2,000 or 3,000 lights are distributed over the same primary circuit. In case of accident by lightning or otherwise, which would disable the converter, the usual effect is to immediately burn out the primary safety fuses of the converter, but, should this fail for any reason, the passage of any abnormal current through the secondary fuses would cut them out, and, failing in this, they would have still between the converters and the lamps the local fuses, which are of still smaller capacity, and therefore readily discharged. I might amplify on these matters to a very considerable extent, but have confined myself to explaining the material matters in which our system has safeguards, which make it absolutely reliable to life and property. In conclusion, I might state emphatically that the converter whether for underground or overhead use, and particularly in the latter event, is an element of safety of a very appreciable amount against danger from currents of higher tension than is used in alternating, which may, by any event, be brought into contact with the primary wires of this system.

Yours respectfully,

O. B. SHALLENBERGER.

WESTINGHOUSE ELECTRIC CO.,
PITTSBURGH, Pa., July 14, 1888.

Mr. C. H. JACKSON,
President, Safety Light, Heat and Power Co.,
New York city.

Dear Sir:—I am in receipt of your favor enclosing a clipping from *New York Evening Post*, which clipping simply is an attack upon the alternating current system, signed by Harold P. Brown.

I have carefully read this article, and beg to call your attention to the following facts and observations in connection with the same. About twenty months ago the Westinghouse Electric Co. began the commercial introduction, on a large scale, of the alternating system of electric lighting. The advantages of this system immediately appealed to the wants and experience of parties already engaged in central station lighting, and of those who, up to that time, had been seriously considering going into the business but had not actually embarked in the enterprise, in consequence of the absence of any system which would fill all the requirements in a commercially successful manner. The first plant introduced by this company on the alternating system in this country was started at Buffalo, N. Y., on November 30, 1886. After that, other plants were rapidly sold and put in operation, until at the date of this letter the Westinghouse Electric Co., and its licensee, the Thomson-Houston Electric Co., have sold in Canada and the United States a total of 127 stations using the alternating system, and of which 98 stations are in operation at the present time, the remainder being under construction. Among these 127 stations there are several which, to the best of my knowledge and belief, are the largest incandescent lighting stations in the world. Notably the Virgin Alley station in Pittsburgh, having a generating capacity of 15,500 16-c. p. lamps, and which, together with its sub-stations operated by the same company (the Alleghany County Light Co.) in Alleghany City and east end Pittsburgh, make a total of 25,800 16-c. p. lamps on the alternating current system in daily use in the cities of Pittsburgh and Alleghany, being a larger number of incandescent lights than are served at the present time from central stations in any city in the United States. The plant of the Denver Light, Heat and Power Co., Denver, Col., which was put in operation in December, 1887, is now supplying over 8,000 16-c. p. lamps. The central station at Richmond, Va., which originally started with 650 16-c. p. lamps and subsequently increased to 2,600 16-c. p. lamps, has now added another increase, giving it a total generating capacity of 7,600 16-c. p. lamps on the alternating system. The station at New Orleans, originally operated by the Southwestern Brush Electric Light and Power Co., but now the property of the Consolidated Electric Light Co., has over 7,500 16-c. p. lamps in successful operation. At Baltimore, Md., the Brush Electric Light Co., of Baltimore city, has just started a station of 5,000 lights. The Richmond Light, Heat and Power Co., of Staten Island, New York, has a station which at present is operating over 4,000 16-c. p. lamps.

Of the stations which are in operation at the present writing, and all of which have been sold and installed since November 30, 1886, 34 have increased their plants since putting them in operation.

You will readily understand, upon a consideration of the foregoing, the enormous amount of work which has devolved upon the officials, electricians and engineers of the Westinghouse Electric Co. in developing and introducing this enormous business within so short a time, and that it has been considered inexpedient, heretofore, to take any notice of, or make any reply to, the criticisms and attacks of some of the opposition electric lighting companies, which have developed recently in a method of attack which has been more unmanly, discreditable and untruthful than any competition which has ever come to my knowledge. The article of Mr. Harold P. Brown, referred to, is a fair sample of the class of attack referred to. I have neither the time nor the inclination to answer in detail the charges brought forward by Mr. Brown, nor, indeed, do I consider it at all necessary, as in spite of this and similar attacks above mentioned, the business of the company is steadily increasing, and the only results produced by such articles are a certain amount of annoyance.

However, I would say, briefly, and all of which we are prepared to have substantiated by an intelligent and thorough test and examination of our system by any competent engineer or engineers:—

In the first place, an alternating current is far less dangerous as to fire or life risks than a current of what is known as the continuous or direct current type. This is a matter which can be readily proved by breaking two currents, one of the alternating and the other the direct, by the same switch. In the case of the direct current a long and vicious spark will occur, and which, if the current is of sufficient volume, will probably melt the edges of the switch. With the alternating current a spark barely perceptible, and with none of the heating and melting defects, will be observed by the same operation. As to life risks, it has been demonstrated to our entire satisfaction and the entire satisfaction of people who have given the subject an intelligent investigation, that the effects of currents of the two systems upon animal life are very unequal, and the effect of the alternating current is immensely less, both as to burning and possible death, than the direct current of the same volume and pressure as explained by Mr. Shallenberger.

Of the 98 central stations of the Westinghouse Electric Co. now in operation, and all using the alternating system, we have yet to receive knowledge of a single case of fire of any description from the use of our system. Of the 125 central stations of the leading direct current company there are numerous cases of fire, in three of which cases the central station building itself was entirely destroyed, the most recent being the destruction of the Boston station; while among the almost innumerable fires caused by this system, among the users, may be mentioned the total destruction of a large theater at Philadelphia, which fire was directly caused by the direct current system of the leading direct current electric light company of the country. Regarding the alleged life risks by the use of the alternating current system, I would say that the potential, or pressure, or electromotive force used on the primary lines with the system of this company is 1,000 volts, as against a pressure on the three-wire, direct current system of 200 volts. Greater care in running these primary wires, either overhead or underground, is required than would be the case if a lower pressure were used, and it is possible under certain contingencies for a person through carelessness to become so connected with these primary wires as to receive a shock which may possibly prove fatal; but this risk is reduced to a minimum. It is a common matter for the three-wire central station companies, using the direct current system, to run a special wire usually for street lighting purposes, carrying a potential on the direct current system of 1,000 volts, and which, as explained above, is certainly more dangerous in every way than 1,000 volts

of the ordinary system. It must be distinctly borne in mind, however, that the street wires carrying the primary current of the alternating system are never carried into the houses, and that the current which goes into the buildings and houses to feed the incandescent lamps has an E. M. F. of 50 or 100 volts as against an E. M. F. of 200 on the three-wire system; and I further state, beyond any possibility of contradiction, that it is utterly impossible by the construction of our apparatus, for a high tension current used in the primary wires to pass the converters and enter the houses. An intelligent examination of the construction of our apparatus will prove this beyond any question of doubt. As to the alleged impossibility of the operation of our system on an underground circuit, I have only to say that any statement of this nature is absolutely and entirely false. The company using our system in Denver, Col., and which has been referred to previously in this letter, has been employing our underground system very successfully with a distributing capacity of over 12,000 16-c. p. lamps. At Springfield, Mass., we have an underground system in successful operation, with a distributing capacity of 2,100 16-c. p. lamps. At the Keystone Light and Power Co., in Philadelphia, they are distributing over 2,600 16-c. p. lights through an underground system.

We are prepared at any time to furnish plans or take contracts for the introduction of our system by underground wires, and to guarantee its successful performance under all circumstances, so long as our plans and specifications are adhered to, and the very successful operation of the three underground stations mentioned, certainly is more assuring in this direction than the very unsatisfactory performance of the underground three-wire system, which underground system has been attended with continual trouble, and has required the most careful nursing from the time it was started up to the present moment. As, for instance, at Detroit, Mich.; Columbus, O.; Chicago, Ill.; Philadelphia, Pa., not to mention others. Whenever local companies are willing to incur the extra investment required for putting the wires underground, we are also prepared to furnish them the system, with sufficient guarantees for its successful performance.

The dismal commercial results so far achieved by the majority of central stations using the three-wire system, owing to the fact that the low tension which they are required to use with that system prevents the possibility of their covering a sufficient territory to ensure a permanently successful business, certainly warrants the expenditure by local companies of a little more cost in insulation and care in construction of their lines to enable them to use such a system as the Westinghouse Electric Co. has so successfully introduced, and by the use of which system any local company can permanently occupy the field instead of being in a position where it is continually harassed, and having its business cut into by other companies coming into the same field while it is itself unable to strike out and occupy new territory.

The idea of locating a central station in the heart of the most thickly populated section of a city or town, as, for instance, the three-wire system in Philadelphia, paying enormous sums for the haulage of coal and ashes and even for the use of water for the boilers, when by the use of the alternating system of the Westinghouse Electric Co. the same stations could be located on some river bank or contiguous to a railroad, thus avoiding all expense of haulage and for water, is surely one which does not appeal to the common sense and experience of the people who are acquainted with engineering enterprises.

In closing, I would call your attention particularly to what is probably the most recent attack against this company, and a consideration of which, together with the accompanying facts as put forth in printed circular enclosed, will, I think, make clear to you the utterly irresponsible nature of the parties carrying on such a campaign against us. I refer to the enclosed circular which has come into our hands marked "confidential to agents," and printed over the signature of Ed. H. Johnson, president of the Edison Electric Light Co.; this company, as you are aware, using what is known as a three-wire low tension system. It is certainly manifest from this that the desperation of the opposition companies has reached a point where even a regard to their own interests is thrown aside, and the only explanation which I can apply to the issuance of the confidential circular in question is to consider it as a last effort on their part.

The previous circulars and pamphlets which have been issued have been all of the same nature, and are all susceptible of exactly as sweeping a reply as this; but, as explained previously, we have felt no injury resulting from the circulation of such literature, and have neither the time nor inclination to reply to it.

Trusting that this rather lengthy letter has, at least in a measure, replied to your inquiries, and again stating that we are ready at all times to invite the intelligent examination of our system by parties who will do so in a fair-minded and straightforward way, and in such manner as was done by the Society of Gas-lighting, of which Mr. Eugene Vanderpoel, president Newark Gas Light Co., Newark, N. J., is chairman.—I remain,

Yours very truly,

H. M. BYLLESBY,

Vice-President and General Manager.

Mr. Wm. H. Browne, treasurer and manager of the Safety Electric Light and Power Co., of New York, who handed in the letters of Mr. Shallenberger and Mr. Byllesby, also presented a communication from himself of much the same purpose and effect as the letters of those gentlemen. Mr. Brown's letter was read.

An able letter from Mr. Seymour G. Smith, president of the East River Electric Light Co., was next read to the board, from which the following extracts are taken :—

"Mr. Brown has further attempted in his article to draw a distinction between what he terms the 'open circuit armature' and the 'closed circuit armature' in regard to the nature of the current, the closed circuit armature being commended because it is supposed to produce a perfectly smooth current, while the open circuit armature is condemned on the ground that it produces a 'pulsating' current, and that the current produced by it is the same as that of a medical battery having an induction coil and a circuit breaker in the primary. There is no similarity, in fact, whatever between the currents produced by these two devices.

"Your board's expert will tell you that an 'open circuit' armature never breaks the circuit for the lamps or other devices, and that there cannot therefore be a current of the same nature as that produced in an induction coil where the primary circuit is absolutely broken. The current of the 'open circuit' armature, it is true, pulsates slightly, as does also that of the 'closed circuit' armature, but the extent of each pulsation is not in either case the whole pulsation of any one part of the armature; but a tendency to pulsation is counteracted by the fact that while the current in one coil is rising or falling, as the case may be, the current in other coils connected at the same time to the circuit is rising or falling, and the resultant effect is a current very nearly uniform. In some machines the tendency to pulsation is further counteracted by what is known as electrical or magnetic inertia of the armature which causes a prolongation of the currents, so that the lapping of the currents upon one another is extended and the sharpness of pulsation reduced.

"There is not, as Mr. Brown would have the public understand, the difference in danger which he assumes between the use of a 'closed circuit armature' and an 'open circuit armature.' The records of deaths do not support his views; and if there be any difference in the number of casualties, we believe that it will be found to be due to the difference in the electromotive force of the machine employed, or to the predominance of the systems using the 'open circuit armature.' The closed circuit armature, as at present constructed, does not lend itself so readily to the production of high electromotive force, and the running of a large number of lamps in series; at any rate, such has been the history of the development of the art. The open circuit machines have been practically constructed so as to run more lamps in series, while the companies using the closed circuit armatures have found difficulty in making successful and reliable machines which would run arc lights in series up to the number which it is possible to employ with the machines of their rivals. There seems to be no doubt that there is a limit of electromotive force and quantity of electric current which can be passed through the human system without producing fatal effects. Just what that limit is with any particular kind of current is not established, and it certainly is not established that any particular kind of current is necessarily more fatal than another. No conclusion on this subject can be drawn from the effects produced by an ordinary induction coil, the nature of whose secondary current differs so greatly from that of arc lighting circuits. If electromotive force or tension were the quality alone which determined the injurious effects of an electric shock, the ordinary induction coil should be far more fatal in its effects than the ordinary electric light current of even (3,000) volts, inasmuch as the electromotive force of the current from the secondary is, as is well known to electricians, enormously greater. The voltage of the alternating current which would be used in practice is like that of the present arc light currents, far below that of a medical induction coil, and there is even reason for supposing that the alternation of current would tend to prevent destructive effects, each current tending to undo the work of its predecessor.

"The rule as to the quality of insulation to be used for out-door arc circuits we see no objection to, and this company, in fact, takes particular care to run circuits of the quality demanded by the rule.

"The sixth rule, with regard to the electromotive force permissible in systems employing alternating currents, is simply prohibitory upon the use of such systems. There is not, even under the most unfavorable view which can be legitimately taken, such a difference in the danger from the use of alternating currents and continuous or ordinary arc light currents, as to warrant the requirement proposed under these rules.

"The first of the suggested rules allows an electromotive force of from 2,500 to 3,000 volts in the case of ordinary arc light currents. The last rule practically allows but a tenth of that voltage in the case of alternating currents.

"It is no more than right that your board should take notice of

the fact that there has been a systematized attack made upon the alternating system by its business rivals, and for that reason alone any objections to the systems should be received without hesitation. The practical commercial advantages of the alternating system are such that it cannot be suppressed. The progress of development of the art of electricity is unquestionably in the line of alternating currents, and for reasons which all electricians will recognize.

"Recent inventions have made it practicable too perate electric motors from alternating currents without the use of commutating or circuit changing devices of any nature whatever in the motors. The importance of this attainment can hardly be over-estimated. It enlarges at once the field of electricity as a distributor of motive power, a fact which certainly should not be overlooked in a city like New York where so many and large manufacturing interests are located."

This company believes that alternating current electric motors without commutators or circuit changers of any description are a practical thing, and the use of such motors on an alternating current system forms a part of the contemplated business of this company, with reference to which it was organized and obtained its charter. Such business must form a large and profitable source of income to every company which shall either purchase or acquire the right to use motors of this description.

The following affidavit, made by W. L. Wright, was presented:

AFFIDAVIT OF W. L. WRIGHT.

PHILADELPHIA, City and County, } ss.

William L. Wright, being duly sworn according to law, deposes and says:—"On the 5th of August, 1887, I was in the employ of the Keystone Light and Power Co. in Philadelphia, Pa., and had occasion to do work in the cellar of the building at Eighth and Chestnut streets, Philadelphia, occupied by Castor & Co. The electric wires in the cellar upon which I went to work had been, until a few days before, used for a 200 volt three-wire direct current system, and a socket had been attached to them by means of a long flexible cord to give a temporary light in the cellar. The wiring had then been changed and connected to the 1,000 alternating current, and, forgetting that this current would be on the socket, I took hold of the socket while standing on the wet ground, when I received a shock which threw me on my face with my hand underneath me, and still grasping the socket.

"I have been accustomed to handling high tension currents, and knew that I was in danger, but was not able to call out to the man who was with me. I retained consciousness for some time, but was gradually rendered insensible. When I came to my senses I was sitting in the cellar held up by two of the men. In the meantime an ambulance had been called, but I refused to go in it, as I did not feel in any way injured except that my hand had been badly burned. I went down to the electric light station and waited there for fifteen or twenty minutes to receive my money, it being pay-day, and then went home. At the urgent request of the officers of the company I went to see Dr. Horace Williams, 1717 Pine street, Philadelphia, who dressed the burns on my hand. These burns healed very slowly; but I have not felt in any way any of the after effects from this shock, such as are usually felt from high tension direct current machines.

"I am familiar with arc light currents, and have received in my business many severe shocks, and I feel sure that had I received this kind of a shock from a direct current machine of any of the ordinary types * * * * * * it would have been fatal.

"I have worked with the alternating current both on the primary or high tension wire and the secondary or low tension wires, and am familiar with the placing of converters in different situations throughout buildings, and when placed, as they are placed in Philadelphia, under a proper set of rules such as the Board of Fire Underwriters have approved in Philadelphia, I do not see how any one can be hurt on the secondary wires, as in case of any accident the safety fuses in the high tension wires melt out immediately, and I think that the high tension wires, when properly boxed in, are a great deal safer than arc light wires can possibly be. And further saith not."

(Signed) W. L. WRIGHT.

Sworn and subscribed to, before me this Seventh day of July, A. D. 1888. }

THOMAS D. SIMPSON,
Notary Public.

Other affidavits to the same effect were presented, signed by John Klepper, Benjamin Acker, Albert Schmid, George Fulton, John Schwartz and C. J. Thompson.

At the request of the board, Mr. T. Carpenter Smith explained the underground system, as used by the Westinghouse company in Pittburgh, and in reply to an enquiry by commissioner Gibbens, said that he considered the subways in New York superior to those used elsewhere in this country. He then dissected a converter for examination by the board, showing that the statements made by Mr. Brown as to its insufficient insulation were erroneous. President Hess then called for the opinion of Mr. H. P. Brown, or any other person who desired to appear and argue against the introduction of the alternating system in New York city, but there being no person present who desired a hearing, the meeting was declared adjourned, subject to the call of the chair.

MR. BROWN'S REJOINDER.

ELECTRICAL DOG KILLING.

At the Physical Laboratory of Columbia College there were assembled on Monday, July 30th, an audience of about seventy-five, upon the invitation of Harold P. Brown, who had undertaken to exhibit the fatal effect of a high tension alternating as compared with a high tension continuous current. Among the gentlemen present were E. A. Leslie, Schuyler S. Wheeler, Theodore Moss, Daniel L. Gibbens, T. Carpenter Smith, C. H. Jackson, W. H. Browne, Jno. A. Howell, E. T. Birdsall, Joseph Wetzler, P. H. Van der Weyde, Wm. Brophy, D. Killicutt and Mr. Curtis.

No intimation of the character of the exhibition had been given, and it is safe to assume that had the revolting nature of the experiments been known the attendance would have been very slim.

A wooden cage, with heavy copper wire interlaced among the bars, had been prepared for the reception of a dog, which was to be tortured by a continuous current and killed by the alternating, in order to demonstrate the dangerous character of the latter.

The dog was dragged into the room and incarcerated before the audience. As he was not yellow there appeared to be considerable sympathy manifested for him, and consequently Mr. Brown felt it to be his duty to announce that he was in reality a desperate cur, and had already bitten two men.

The dog weighed 76 pounds, and although his character had been villified his mild appearance suggested that there might be another side to this story if a friend had been present to state it. Mr. Brown then read a lengthy paper, in which he laid particular stress upon the fact that he was not in the employ of any electrical company, but that he had been actuated in this matter by a desire to prevent loss of life arising from the indiscriminate use of high tension currents.

In order to assure the audience that the experiments would be fairly conducted, he requested A. E. Kennelly, of Edison's laboratory, Dr. Schuyler S. Wheeler, of the Board of Electrical Control, and T. Carpenter Smith, to assist in the demonstration.

The connections with the dog were made to his right fore leg and left hind leg by wrapping them with wet waste, bound on with No. 20 bare copper wire. The resistance of the dog and his connections was measured under the supervision of Dr. Wheeler, and announced to be 15,300 ohms. The strength of current was two-tenths of an ampere. A relay had been introduced into the circuit, so that the extra current from the discharge of the field magnet would not reach the subject. This is the device recommended by Mr. Brown, and he stated that without its use 500 volts from the continuous current machine would cause death. Various tests were made with an electromotive force of 300, 400, 500, 700 and, finally 1,000 volts from an Edison "municipal" dynamo, the effects of which upon the doomed animal were heartrending in the extreme. As the voltage was raised, and the dog, in his frantic efforts to escape, succeeded in forcing his head through the meshes of the wire enclosure, many of the spectators left the room, unable to endure the revolting exhibition. By the continuous application of high tension currents the resistance of the dog was reduced to 3,500 and finally to 2,100 ohms, and his vitality had been so reduced that it was a question with the audience whether he was dead or alive.

Mr. Brown announced that he could produce a still higher voltage, but there was no desire to witness the further torturing even of a vicious dog, and the chief executioner sarcastically stated that he would then introduce the alternating current in order to make the victim "feel better," such having been stated by advocates of the converter system as the effect of the current used by them.

A gentleman in the audience here protested, in the name of humanity, that this particular dog be killed at once. As Mr. Brown claims to be a voluntary representative of the cause of humanity he acquiesced, and an electromotive force of 330 volts ended the death struggles of the tortured victim. The ampere measurement of the alternating current could not be determined, therefore the whole exhibition proved nothing beyond the fact that a continuous current of 1,000 volts and $\frac{2}{10}$ amperes while it will not kill a healthy dog, is far less satisfactory to him than an alternating current of 330 volts electromotive force and unknown volume.

A protest was made by a reporter of the daily *World* against a continuance of the inhuman performance, and an agent of the Society for the Prevention of Cruelty to Animals intervened at once, and stated that while experiments of this nature, conducted

by colleges and institutions for the benefit of science, might be permitted, he should prohibit their continuance in the interests of rival inventors.

There was a general feeling of relief at this humane interference. Dr. Frederick Peterson, who has assisted Mr. Brown in his investigations, then read a paper upon the effects of electric currents upon living animals, which closed an exhibition, in comparison with which a Spanish bull-fight is a moral and innocent spectacle.

THE EDISON LAMP PATENT ADJUDGED INVALID IN ENGLAND.

Mr. Justice Kay delivered judgment July 19th. The trial occupied the time of the Court for no less than 21 days, the Lordship reserving judgment at the conclusion of the arguments. The action was by the plaintiff company to restrain an alleged infringement of their patents by the defendants, Mr. William Holland, the manager of the Albert Palace, Battersea (where incandescent lamps had been used which, it was said, were substantially the same as those protected by the plaintiffs' patents), the Jablochkoff and General Electricity Co. (Limited), who had supplied the lamps used at the palace, and the Anglo-American Brush Electric Light Corporation (Limited), who were the manufacturers of them, and had entered into an agreement with the Jablochkoff company to indemnify them against the litigation. The patents upon which the plaintiffs sued are the same as those they succeeded in maintaining in the Court of Appeal last year, in two actions by them against Messrs. Woodhouse and Rawson—namely, the Edison patent, No. 4,576, of 1879, for the incandescent lamp, and the Chesebrough patent, No. 4,874, of 1878, for a mode of making uniform the carbon filament or thread which forms the light giving portion of the lamp. The cases against Messrs Woodhouse and Rawson will be found reported in *The Times* of May 23, 1886, and February 13, 1887; also in *The Times* Law Reports, vol. 2, pp. 654–656; and vol. 3, pp. 327, 367. During the delivery of Mr. Justice Kay's judgment, which occupied nearly an hour and a quarter, the Court was crowded to excess with persons of eminence in the scientific world, besides the general public.

Mr. Justice Kay said—The plaintiffs sue the defendants for infringing two letters patent; one Edison's patent, No. 4,576, of November 10, 1879; the other Chesebrough's patent, No. 4,874, of 1878, amended by disclaimer dated the 12th of November, 1884. Both patents relate to electric incandescent lamps. The defense is taken up by third parties, the Anglo-American Brush Electric Light Corporation. The validity of both patents is put in issue. The first thing necessary is to ascertain as accurately as is possible to any one who has not had the requisite scientific training, what was known on the subject at the date of these patents, say in 1879. There are two commonly known systems of electric lighting, the arc and incandescent systems. These patents relate to the latter. The former depended upon a break in the conducting material occurring at a point where the conductor was carbon in the form of a pretty thick pencil. The current leaped over the break in an arc, gradually destroying the carbons; and this arc gave a vivid white light, especially at the positive pole. The incandescent system is different. The conducting material in this is continuous, without any break or actual interval; but, being in part an imperfect conductor, that part becomes heated by its resistance to what is called the passage of the current, and this heating, raised to an intense degree, gives the light (now familiar to us) in the incandescent lamp. The material which is now so heated is some form of carbon. It was well known that this was a good material for the purpose, because it was an imperfect conductor—in other words, had a high specific resistance—and that it was essential to use it in a vacuum or in some gas or vapor which did not contain oxygen, otherwise the carbon consumed quickly. Until 1872, when Sprengel's air pump was improved by Mr. Crookes, it was difficult to obtain a vacuum which was complete enough. The consequence was, that it was necessary to employ a pencil of carbon of comparative thickness, because there was enough oxygen left within the exhausted glass bulb to occasion some consumption of the enclosed carbon, and also enough air to diminish the bulk of the carbon when incandescent by frictional action upon its heated surface, which Edison in his specification and some of the witnesses have called "air-washing." Another difficulty which prevented the use of very slender carbons was the irregularity of the current obtained from the dynamo. It was subject to variations, which at times produced a current stronger than the carbon could bear. This was remedied by the improvements of Gramme and Brush, which were perfected in the year 1878. Two modes of improving the resistance of the carbon were known, one by increasing its length, the other by the diminution of its thickness—or, to use the more exact language of the witnesses, of its sectional area. It was known that the carbon for an incandescent lamp must be enclosed in a glass bulb from which the air must be exhausted. Bulbs made entirely of glass had been used and publicly exhibited for this purpose. It was known that molten glass could be made to adhere closely to platinum wires, because the glass proper for the purpose expands with heat in the same degree as that metal, and that for this reason, and also because of its properties as a conductor of electricity, the best mode of connecting the carbon within the glass bulb with the main wires through which the current passed, was to unite each end of it to a thin platinum wire, and to fuse the glass round these wires so that air should not penetrate at the points at which they entered the bulb. It was known that by increasing the electromotive force the main wires bringing the electric current to the lamps might be reduced in size, just—to take the illustration given by Sir F. Bramwell—as by increasing the hydraulic pressure in the pipes supplying a town with water, you are enabled to use smaller pipes, because the water will pass with accelerated velocity. It was known that by using high resistance in the incandescent portion of the lamp smaller leading wires might be employed, and also a greater number of lamps might be illuminated from the same source of electricity by working them, as Dr. Hopkinson calls it, in multiple-arc or in parallel. Two systems of using incandescent lamps were known, and it was recognized that when many lamps were to be lighted from one central station, and at some distance, the system called "multiple-arc" or "in parallel" was best. That may be shortly described as a plan involving the use of one main leading and one return wire, each lamp being supplied with electric current by a smaller wire from the main leading wire, and returning such portion of the current as it took to the return wire, the main leading wire and the return wire being supposed to be parallel. The other system, which is little employed, was the use of lamps "in series." In this case the whole current is sent through each lamp in succession, and accordingly lamps of comparatively low resistance are required. The *desideratum* in 1879, was to obtain lamps of high resistance for the "multiple-arc" system, which could be made "commercially," that is, in large quantities with reasonable cheapness, and, above all, that should have durability. Edison, Lane-Fox, Swan, and others, had been working with this object in the same direction. On the 19th of December, 1878, in a lecture given by Swan at Newcastle, he described an experiment on the production of light by passing a current of electricity from a dynamo through a slender rod of carbon inclosed in an exhausted globe. On January 17, 1879, he lectured on the same subject at Sunderland, illustrating his lecture by experiments, exhibiting certain electric lamps. On the 4th of February, 1879, he again lectured at Newcastle, and he then exhibited the lamp which has been produced in evidence. It consists of a bulb made entirely of glass with leading platinum wires sealed into it, and connected with a pencil of carbon inside the bulb. This piece of carbon was obtained from Carré, of Paris, and was manufactured by him and shaped before being carbonized. It is $\frac{1}{25}$th of an inch in diameter, that is, considerably thicker than the carbons now used, and, being straight, the leading wires are sealed into the bulb at opposite ends. This renders it liable to a defect which is alluded to in the correspondence between Swan and Mr. Stearn—viz., rupture of the carbon, or its separation from the wires by expansion and contraction under the great heat to which it is exposed. This lamp was exhibited again at Gateshead on the 13th of March, 1879, and seems to have been kept lighted for 10 to 20 minutes at a time on two or three occasions without injury. I have no evidence how long it would last if continuously used. Swan, in the spring of 1879, ordered from Carré carbons in the shape of a hair-pin, a model of which he produces. It is practically identical in form with some of the carbons now used in lamps, but with a larger sectional area. Lamps made with these would not have the defect to which I have alluded. He says that probably towards the end of 1879, he made some lamps with those hair-pin carbons. They are referred to by Mr. Stearn in a letter dated the 26th of November, 1879, in which figure 2 is a sketch of a lamp so mounted, but I do not lay much stress upon this as an anticipation of Edison, for, although Heaviside and other witnesses speak of having seen these lamps in 1879, I think the fair result of this evidence is that these were experiments which did not succeed in producing a commercially successful result before Edison's patent. On the 2d of January, 1880, Swan obtained a patent for one of the most valuable inventions connected with the manufacture of incandescent lamps. That was for preparing the carbon by passing the electric current through it, and heating it to incandescence while the bulb was still connected with a Sprengel air pump in action. This is now always done, and the effect is to make the vacuum much more perfect, or, rather less liable to be impaired by air or gas coming from the carbon itself when first heated in a vacuum. On the 21st of January, 1880, he obtained a patent for a horse-shoe strip of cardboard prepared for an incandescent lamp by converting it into a substance like parchment by treatment with sulphuric acid and then carbonizing. On the 27th of November, 1880, he obtained a further patent for the application of this process to cotton thread. This has proved a most valuable invention. It produces a non-structural tough material, said by one of the witnesses to be hard and stiff as a metallic wire, and this is now largely used for incandescent lamps. Mr. Edison applied to the object of producing a lamp of high resistance his untiring and apparently inexhaustible ingenuity, but his specification shows—as Sir F. Bramwell states—that he was not aware how much was actually then known to electricians like Lane-Fox and Swan, and

Edison conceived that he was the first inventor of some matters in which they seem to have anticipated him. Edison availed himself of the more perfect vacuum obtained by the Sprengel pump, and also of the known principle of increasing the resistance of the carbon by diminishing its sectional area, which had become possible to a much greater degree owing to the perfecting of the Sprengel air pump and the dynamo. The most important point raised upon the construction of his patent of November 10, 1879, is the extent of the second claim—whether it includes every lamp of the kind there described, the light giving carbon in which is a "filament;" or, whether it means only lamps with such filaments as are particularly mentioned in the body of the specification. Another point is upon the first claim, whether the word "lamp" in that claim does not mean merely the filament of carbon. A third question of construction is whether the carbonization of the filament is to be effected before or after it is attached to the platinum wires. With respect to the sufficiency of this specification, it is urged that Edison ought to have defined exactly what was meant by the word "filament," and that his patent of 1879 is void for insufficiency of specification in this respect, and also because it does not give sufficient directions for carbonizing filaments. None of the modes of making filaments particularly described, it is said, are practical; or, at any rate, some are not, especially the several modes of making filaments from a putty composed of lampblack and tar, and from that putty compounded or coated with various substances. Also, if the patent means that the filament is to be carbonized after being attached to the platinum wires, this, it is said, is impracticable because the platinum wires would thereby be made porous and brittle, and could not be sealed into the glass so as to prevent air getting in at the point of sealing, or through the pores in the wire. His lordship then referred to "Neilson *v.* Harford" (8 "M. and W.," 806, and "Simpson *v.* Holliday,") (13 "W. R.," 578, "L. R.," 1 H. L., 315) as to the proper mode of construing a specification, and proceeded: With regard to the construction of Edison's patent, No. 4,576 of 1879, I observe, first of all, that the provisional specification begins by stating the necessity that lamps connected in multiple should be employed without main wires of great size, and that it is essential that these lamps should have a high resistance. It is stated that this had been set forth in a previous patent of Edison's of the same year, and that lamps of great resistance had been obtained by a long wire of platinum or other metal pyro-insulated (which means coated with an incombustible substance) and coiled so that but small radiating surface was exposed. Then it is said that the present invention relates to lamps of a similar character, except that carbon threads or strips are used in place of metallic wire, and connected to platinum wires sealed into a bulb exhausted of air. A description of the mode of manufacture is then given, but not in so much detail as in the complete specification. Turning to that I find that it commences with a short statement that the object of the invention is to produce incandescent lamps of high resistance. Then follow four paragraphs stating in what the invention consists. The first of these is the coiling of carbon wire or sheets, so as to offer great resistance and present but a slight surface for radiation. The next the placing of such light giving body of great resistance in a nearly perfect vacuum. The third states that the connecting wires are platinum sealed into the glass. The fourth is the method of manufacturing carbon conductors of high resistance, and securing perfect contact between them and the wires. The specification next states Mr. Edison's view of what had been done up to that time. It is admitted that this is inaccurate in many respects. He appears to have been unaware of the attempts that had been made to do the very thing at which he was aiming —that is, to increase the resistance of the carbon burners in lamps made of bulbs of glass exhausted of air, the connecting wires being of platinum sealed into the glass. He seems ignorant that bulbs made entirely of glass had been used, or that they had been exhausted of air so as to form a vacuum. His Lordship then read Mr. Edison's description of the several modes of making the carbon burners, and proceeded: Then come the claims, which are four in number "(1) an electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance made as described and secured to metallic wires, as set forth; (2) the combination of a carbon filament within a receiver made entirely of glass through which the leading wires pass, and from which receiver the air is exhausted for the purposes set forth; (3) a coiled carbon filament, or strip, arranged in such a manner that only a portion of the surface of such carbon conductor shall radiate light as set forth; (4) the method herein described of securing the platina contact wires to the carbon filament and carbonizing of the whole in a closed chamber, substantially as set forth." I do not agree that the word "lamp" in the first claim means only the "filament of carbon." The claim is, "an electric lamp for giving light by incandescence," which the filament alone could not do. The words "consisting of" are inapt, but the wording of the whole specification is exceedingly inaccurate, and this is only an example of such inaccuracy. "Containing" would have been a better word. I construe this claim to mean lamps such as described in which the distinguishing features are carbons of "high resistance, made as described, and secured to metallic wires, as set forth." After commenting on the other claims his Lordship proceeded: The claims, as I read them, are—(2) a combination of four requisites for a lamp; (3) and (4) claims for two of those requisites separately; and (1) a claim for particular modes of making and attaching to platinum wires the first item of the combination—viz., the carbon filament. But claim (2) comprehends lamps containing carbon filaments, however made, and not only those made in the special modes described in the body of the specification and included in claim (1). The defendants construct incandescent lamps with all the four elements of the combination described in Edison's second claim. But the filament made by them is essentially different from anything particularly described in Edison's specification. His Lordship then described the defendant's mode of making the filament used by them, and continued: As I have come to the conclusion that Edison's second claim is wide enough to include any lamp with a carbon filament, however made, the defendants have clearly infringed this claim. Then comes the serious and important question whether so wide a claim can be supported. I have already pointed out that the only item of the combination which had any novelty was the use of the filament or "very slender thread" of carbon. Edison had managed to use carbons thinner than any one had used previously. The only advantage of a "filament" suggested in the specification is its high resistance by reason of its thinness or small sectional area. There was no invention described in this specification of any new principle. The principle of increasing resistance by diminishing the sectional area of the carbon was known, and had been published by Lane-Fox and by Swan before November, 1879. Assuming that Edison had been the first successfully to put that principle in practice by the methods described in his specification, did that success entitle him to say "no one shall make a lamp with a filament of carbon but myself?" Suppose the claim had been thus worded—"I have succeeded in making an electric lamp with a carbon burner, say, 1-100th of an inch in diameter, which gives a high resistance, and I claim a monopoly of all lamps with carbon burners but thicker than that, however made." Could such a claim be supported? That, in effect, is Edison's second claim. One of the objections made is that the claim ought to have been worded in some such way as I have just suggested, in order to make it sufficiently definite. In other words, Edison ought to have indicated the exact boundary between his "filament" and such a Carré carbon as Swan had successfully used. From the drawings and from the great stress laid upon coiling the filament, the only object of which seems to be to increase resistance by using a considerable length, I should conclude that Mr. Edison did not conceive that extreme thinness of the carbon was practicable. Mr. Swan had tried paper, cardboard, and similar materials carbonized, and, if he had not tried a "filament," he had used and obtained considerable success with Carré carbons not more than 1-25th of an inch in diameter. He was trying these in the form of a hair-pin, made and shaped to that form before carbonization; and it seems impossible to say that Edison, by reducing the thickness of the horse-shoe carbon, had made any vast invention or contributed largely to the knowledge which such inventors as Swan and Lane-Fox already had on the subject. His lordship then referred to "Jupe *v.* Pratt" 1 "Webst.," 146) as an authority on the right of an inventor to be protected in patenting a practical mode of applying a new principle discovered by him, and proceeded: But is there any decision that an inventor who has discovered a mode of applying a known principle like this, of increasing resistance by diminishing the sectional area of the carbon burner, can obtain a monopoly of the principle? Sir F. Bramwell, in his evidence for the plaintiff, put the case in the strongest and most favorable manner by saying that Edison made the first commercially successful incandescent lamp. Unless that is so his claim to so large a monopoly would not, in my opinion be arguable. I proceed to inquire—Did he make a commercially successful lamp—that is, were any of the modes of making lamps particularly described in the specification commercially successful? Justice Ray then referred to the numerous other electric patents taken out by Edison, and proceeded:—The plaintiffs have been challenged again and again during the cross-examination of their witnesses to prove, if they can, that any lamp with a burner made according to the description in the body of the specification of November, 1879, has been brought into the market in England or in America. No evidence of this has been given, and I conclude that there was no commercial use of the invention of that kind. Until he had taken out his subsequent patents it seems that Edison did not introduce any lamp to the public. The Justice then referred to certain experiments which had been made in constructing lamps under the patent of 1879, and continued:—With respect to the commercial success of the invention as tested by these experiments, I find from the report and a supplemental table of results which has been handed to me as an agreed statement, that out of 100 lamps some broke down at once, 13 lasted less than 10 hours, 11 more less than 20, 18 more less than 40, and only six above 40 hours, of which four were unbroken at 60 hours, and of these four there is no further record. That is far from commercial success. No system of electric lighting could be maintained, except at an expense which could not practically be incurred, with lamps of such short life as

these; and this explains most satisfactorily why Edison never sold lamps made according to the specification of 1879. In considering the sufficiency of this specification, it must be remembered that in 1879, there was no trade or business of manufacturing electric incandescent lamps. Lane-Fox, Edison, Swan, and other inventors, had given much time and attention to the subject, but except such persons there were none who had any special knowledge in the matter. The *dicta* that may be found in some cases that the specification of certain patents must be read as addressed to adepts in the particular trade or business do not apply. For this reason it was essential that the specification should be carefully explicit. It ought to be such as would enable an intelligent working man to make an incandescent lamp without having to try experiments. The Justice then examined the specification on the question of sufficiency of description, and arrived at the conclusion that it was vague and insufficient. His Lordship then proceeded,—My opinion is that the patent of Edison's, No. 4,576, of 1879, is invalid—first, because the second claim is for a monopoly of incandescent lamps containing a filament of carbon for a burner, which claim, I think, is far too wide, considering how little Edison had actually invented; secondly, because his specification does not describe a lamp which ever became, or, as I think, could have become, commercially successful; thirdly, because the directions therein contained are so insufficient that no one could have made the carbons he describes without considerable previous experiment; fourthly, because one of the processes described—viz., mixing the carbon with a volatile powder—I believe to be practically injurious if done as Edison directs; fifthly, because the coating with a non-conducting, non-carbonizing substance, if not injurious, is of no practical utility; sixthly, because the same may be said of coiling the filaments, on which the patentee lays great stress. This patent of Mr. Edison's, No. 4,576, of 1879, has been the subject of litigation in a previous suit between the present plaintiffs and Messrs. Woodhouse & Rawson, who were manufacturing incandescent lamps and were sued by the plaintiffs for infringement. The case went to the Court of Appeal, and both in the Court of First Instance and in the Court of Appeal the patent was treated as valid, though apparently with some hesitation. I am bound by these decisions, and should follow them, of course, whether I agreed with them or not, if the evidence in the two cases were the same. But that is not so. On one point which Lord Justice Cotton seems to have thought essential the courts were completely misled. They were given to understand that the carbon burner in the lamp exhibited by Swan before the date of Edison's patent was shaped after and not before carbonization. It is now admitted this was not the fact. It was a carbon made by Carré and used as made by him without alteration. But, further, I am told that there was no evidence in that case as to the difficulty of making the carbons described in Edison's patent from the description in the specification. I understand that no contest took place as to the sufficiency or utility of any part of Edison's patent, and that nothing like the evidence as to the previous knowledge on the subject was given in that trial which has been adduced in this. With respect to the construction of the patent, the opinion which I have expressed agrees with that of the majority of the learned judges in the Woodhouse & Rawson trial. The case has been brought before me with such an elaboration of evidence on every point that I think myself bound to act upon my own opinion, believing as I do that if the same materials had been before the learned judges in the other case they would have arrived at the same conclusion as I had done. The other patent in question in this action is Chesebrough's, No. 4,847, of 1878, amended by disclaimer dated November 12, 1884. The specification describes and claims a method of preparing the illuminating portion of an electric lamp, and also a material for the manufacture of illuminating carbons. Shortly stated, the carbon to be prepared is surrounded with a carbon gas or liquid and then heated intensely by the passage of the electric current. This causes a decomposition of the surrounding hydrocarbon, and the deposit upon the heated surface of an extremely dense form of carbon, such deposit being in greater quantity upon the hotter—that is, the thinner—portions. The specification states that "carbon of the ordinary sort, when heated by the electric current, exhibits points and lines of unequal brilliancy. Carbons prepared by this process when so heated glow with a uniform brilliancy throughout." A French chemist, Despretz, in experimenting on the reduction and volatilization of carbon, discovered that when the carbon was heated in an atmosphere of hydrocarbon this deposit occurred and interfered with his operations; and he describes this in a paper which was published in England some years before 1879. But Despretz did not utilize this product in any way, and his experiments had nothing to do with electric lighting. Assuming that Chesebrough derived his knowledge of the mode of producing this material from Despretz's paper, his invention consists in applying it for the purpose of making uniform the light giving power of a piece of carbon when heated by the electric current; and the beauty and merit of the invention consists in thus enabling an imperfect carbon, by a sort of automatic operation, to improve and perfect itself. I have no doubt that this is a good subject for a patent. I had more hesitation upon the claim for the material, which certainly was not discovered by him; but that is not the whole of the claim. It is for "a material for the manufacture of the illuminating conductors of electric lamps produced by electricity heating carbon in a carbon gas." That does not prevent any one from making the same material and using it for other purposes. The claim is really for the use of the material for the burner of an electric lamp. This seems to me equally valid. Another objection—that pencils cut from the lime cylinder coated with carbon would not make effective carbons—seems to me to arise from a misconstruction of the specification. It is not the lime cylinder, but the deposit of carbon which is to be made into burners. The defendants have used this process of Chesebrough's, but they say for a different purpose. Their object is to bring all their carbons to one standard of illuminating power, an operation for which they have invented a somewhat cacophonous word—"standardizing." But Sellon, one of their principal witnesses, admitted that the process would cure any inequalities of light giving surface in the particular carbon so treated. These, he says, in their cellulous carbon threads seldom occur. However, I cannot resist the conclusion that the defendants, by this use of the process for carbons of incandescent lamps, are infringing Chesebrough's patent. The plaintiffs' reply in this case was, unfortunately, interrupted. The Attorney-General asked leave, if the Court wanted more assistance on any point, to add somewhat to the reply. I have not thought it right to trouble him further. Every point has been put again and again to the scientific witnesses. Twenty-one of the working days of the Court have been occupied by this case. I have not arrived at the conclusion I have intimated without thought and care, and I do not think that further argument would be a useful expenditure of public time. I must therefore decline to trouble counsel any more in the case. I have been provided with a copy of the print of the shorthand notes. They contain, as is, perhaps, inevitable in such a case, a considerable number of verbal inaccuracies, some of which completely distort the meaning of what was said. The action, so far as it relates to Edison's patent of 1879, must be dismissed with costs. There must be an injunction to prevent any further infringement of Chesebrough's patent, and the defendants must pay the costs of this action so far as it relates to that. The costs must be set off in the usual way.

THE GAULARD AND GIBBS PATENT ANNULLED IN ENGLAND.

DECISION OF JULY 9.

Mr. Justice Kekewich, in delivering judgment, after referring on the question of nonconformity of the complete with the provisional specification, to the observations of Lord Blackburn in Bailey *v.* Robertson ("L. R." 3, App. Cases, 1,055), said that the amendment of the complete specification had the effect of substituting the specification in its present form for the original; but in its amended form it must comply with the provisions of the law, including those as to conformity with the provisional specification, as explained in Bailey *v.* Robertson. The provisional specification in the present case spoke of an "unlimited number of induction coils," whereas the complete specification spoke of "a number" only. Was this an essential difference? His lordship decided this question in the negative. One passage of the provisional specification was as follows:—"When an electric current approaches or recedes from a circuit of solenoidical form, it determines in this latter a current of induction without in any way modifying the value of the primary current." It had been said that the provisional specification depended on the statement "without in any way modifying the value of the primary current," and that this was false and was abandoned in the complete specification. His lordship continued as follows:—That that is false is conceded, and for the present purpose it may be assumed that it is abandoned in the complete specification, but I do not think that that fact is fatal to the patent. It may be important as regards utility and also relevant on the question of novelty, but it does not establish nonconformity between the two documents. The most that can be said is that the provisional specification contains, but the complete one omits, an erroneous statement respecting the patented invention which, if scientifically true, would add greatly to its value. That to my mind is not enough. But it is said that, whereas the provisional specification rests the invention on induction coils of a special construction, the complete specification as amended applies it to induction coils of every character, and this makes the latter different in the sense of being more extensive. This is a formidable objection if true. The foundation of it is the abandonment of the claim for special construction. But the patentee, though he has done this—though he has said, "I do not claim to have any special form of induction coil"—has retained, as part of his combination, the use of those of a special construction. He does not claim to construct, but he requires to use certain instruments, and those only when constructed. What is the effect of this on the complete specification standing alone is another question, but on the question of conformity I hold there is no such difference as is alleged between the two documents. Each asserts the necessity for a secondary generator of a special construction. So far, I have dealt with mere questions

of language, so as to enable the Court to read the documents for the above purpose. In further examining the specification (and henceforward I deal with the complete one only) one depends much on evidence. There are still questions of construction to be solved, but evidence is required not only to explain terms of art, but to prove what was known at the date of the patent. I may mention here one objection, out of order, to get rid of it. It has been stated by the patentee (Gibbs) that the invention is not thoroughly successful unless there is an equal mass of metal in the primary and secondary wires, and it is urged that, whether true or not, which is said to be immaterial, this ought to have been in the specification. If true, it might, with advantage, have been stated, but it only comes to this, that what is possible with unequal masses and is more feasible as you approach equality, can only be made a thorough commercial success when that equality is practically attained. I do not think that the omission to make such a statement can defeat the patent. Another objection urged respecting secondary generators was that a divided core is essential, and that this is not stated. It is, without doubt, stated as regards the first, and the evidence has satisfied me that it is sufficiently implied in the language describing the second; and further, that no electrician would stop to enquire whether a solid or divided core is intended. But, putting aside these two objections to the description of secondary generators, and assuming, of course, the soundness of my view that they are of special construction, how does the specification stand as regards the information given for their selection? And, in order to get an answer to this question, first consider what information is reasonably required? A patentee is bound to tell the public in his specification, not only what his invention is, but how practical effect is to be given to it, and if the invention be a machine, how that machine can be manufactured. I have paraphrased the statute. If there are many different ways of effecting the entire object, or any particular part of it, he is not bound to specify them all in detail, but he is bound to give such instances—selections it may be from a class—as will enable a competent workman to know what he ought to use. And he is further bound to refer to these instances, or the class from which they come, in language which leaves no doubt what articles are and what are not applicable to the production of the intended result. This is important for two reasons—first, in return for his monopoly, a patentee is bound to put the public in possession, as far as description can do it, of his invention in principle and detail; and, secondly, as a condition of being entitled to restrain other operators from producing his result by the same means, he is bound to tell them precisely what they cannot do except under penalty of an injunction with its serious consequences, and thus to indicate what can be done safely. This is not less true where the patent is for a combination than in any other case. Indeed, I am not sure that the obligation ought not in such a case to be particularly strict. If a man says, "I claim to have protected as my invention, three things combined which, though separately well known, have not been before used together," it is reasonable and right that he should state exactly what each of those three things is; and if any of them belongs to a class comprehending several varieties, then also which of the varieties are intended. And this, of course, he can easily do, as, admittedly, the combined items are well known. What is the combination, several times described, with some variation of language, but none of substance? Take it from Mr. Aston's statement to his own witness, Dr. Hopkinson. The combined elements are three in number—1, an alternating dynamo supplying a main wire; 2, a current in that wire of high tension; 3, a secondary generator such as is described. The description there mentioned is that of the witness, but of course he could only explain or illustrate, he could not go beyond the specification. In passing, let me observe that I am not satisfied that there are really three elements, but I will not dwell on this. Let it be assumed for the present purpose that there are three items—the alternating dynamo, the high tension, and the secondary generators, described in the specification. There is no difficulty about the first or second, but how has the patentee fulfilled his obligations as regards the third? It is conclusively proved by the petitioners, and not denied by the respondents, that there is nothing special about the secondary generators described, that they differ from others of their class only in unessential details, and that any other instrument of the class—induction coils with divided core—would answer the purpose equally well. So completely is this admitted by the respondents that they contest the conclusion that a special construction is intended. No more about that. Is it reasonable to hold that the divided core is the special construction? I think not. It would to my mind be pressing the maxim *ut res valeat* too severely to construe the words "electrical generators of special construction" to mean those belonging to one of two well-known and exhaustive classes, especially when one finds no reference to that class as a whole, but an elaborate description of two particular specimens. If the intention had been to refer to electrical generators having a divided core, that might have been easily done in a single line, and the examples would have been needless and out of place. Then it is urged that the special construction refers to the diminution of tension to those which, receiving an electric current of high tension, pass it on as a current of low tension. It is not pretended that this is said in so many words; no counsel or witness has ventured to put his finger on an expression which states plainly that the secondary generator employed must be of what is styled the "step-down" character. It is conceded that no other will do, and it may be assumed that no other would be attempted by a competent workman; but this is because of a well-known scientific fact, and not because of information given by the patentee There is no occasion to examine the provisional specification on this point or to inquire whether the complete specification in its original form is agreeable to the view now taken of it as amended. I hold that, as amended, it does not say one of the elements of the combination is a step-down induction coil. That is what you are to use with an alternating dynamo and a high tension primary wire, in order to produce the desired result. Nothing less than this would suffice. It is not enough to say, as the patentee does, that the quality and value of the induced currents depend on the special construction of the electrical generators without giving a plain statement in what the special construction consists. It is not suggested that the examples are exhaustive of the class of machines which would answer its purpose. I think that a manufacturer is placed by this specification in a difficulty. He knows, of course, that he cannot use either of the induction coils described, but if he wishes to use one of the same class, but differing in detail, he cannot ascertain from the specification whether he may safely do so or not. Changing the phrase, the patentee has not in his complete specification ascertained the nature of his invention, and how it is to be performed, in that he has not explained what constitutes the third item in his combination. Mr. Aston says, of course the use of equivalents would be an infringement, but I do not think that doctrine can be called in aid of a patent which professedly rests on a special construction. In its original form the specification claimed the special construction of the secondary generators required to produce the desired result. Apart from any question respecting conformity with the provisional specification, the patent could then have been supported, so far as language was concerned; but the patentee was driven to abandon this part of the claim and to amend by way of disclaimer. This was a difficult task. I am disposed to think that it could not have been performed without destroying the patent—could not, that is, have been so performed as to leave a supportable residue. But whatever was possible, I hold that it has not been done, and that, with the abandonment of the third item of claim, the whole specification falls to the ground. This holding makes it unnecessary to go into the question of anticipation. The evidence on this point is conflicting, and I have the testimony of men of acknowledged eminence and truthfulness on either side. Besides this there are many documents, and the criticism of them has been long and minute. Before pronouncing a deliberate opinion on the question I should be obliged again to examine those documents by the light of the evidence, which would have to be reperused for the purpose, and of the arguments, which would have to be recalled and weighed with regard both to documents and evidence. I do not consider myself called upon to do this; but it may be convenient for me to state what, subject to such revision as I have just mentioned, is the result of my best attention during the trial. I do not question —nobody could successfully question—the accuracy of Mr. Aston's distinction between anticipation by documents only—what is sometimes called paper anticipation—and that by manufacture or use. It is grounded on common sense and established by the authorities to which he referred, and many others. Guides for the application of the distinction are also to be found in those cases, and notably in the judgment of Lord Westbury, which Mr. Aston quoted. But the distinction concedes that there may be a paper anticipation, and the question here seems to be whether the documents which have been referred to, did not separately or together add so much to the stock of common knowledge that nothing remained for invention within the limits of Messrs. Gaulard and Gibbs' specification. Mr. Aston observed that about the years 1878-9 there was an avalanche of patents, and he accepted my suggestion that many inventors were buried in it. He did not pursue the analogy further, and perhaps forgot that a congealed mass has a law of motion of its own which after a time again brings to light, capable of recognition, though it cannot revivify, buried limbs. So here science has progressed, and in its progress has again called attention to discoveries of bygone years, long buried and forgotten, and of which Sir William Thomson was in 1881 either ignorant or oblivious. Being brought to light, they are recognized as bearing a striking resemblance to others since called into existence, and there is at least some ground for arguing that there is no substantial difference between the past and present. There is often a genuine and complete answer to an argument of that kind. Why, says the patentee of later date, why was not this old invention put in practice if, as you say, it anticipated mine, which has been proved to have been feasible and useful? It is frequently difficult—it is sometimes impossible—to give a satisfactory reply to such an objection, but I think that Sir William Thomson gave one in this case. He says that at that time, the period of those numerous patents, there was no demand for electric lighting—no encouragement, that is, for inventors to

persevere and put their inventions in practice. That would scarcely have sufficed; but he added, in effect, that there was not then known any lamp to which those inventions could be usefully applied, that failing any such lamp they necessarily slumbered, but that, such a lamp having been now discovered, their character and value are apparent. That reply, to my mind, detracts largely from the force of the objection to which I have referred. As at present advised, I fail to see how Messrs. Gaulard and Gibbs made any discovery in the technical sense of the word, or, rather, what they published to the world which was not already disclosed by some one or more of the earlier specifications. As I do not propose to examine any of them in detail I will not mention more than one, which was not, I think, the one mostly relied on by the petitioner, and possibly is not the best example. I refer to the specification of Charles W. Harrison, of March 1, 1879. You cannot, it seems, take his description of the third part of his invention any more than you can take any other of the specifications and therefrom build a complete machine according to Messrs. Gaulard and Gibbs' patent—that is, some ingenuity would be required to supplement the directions given. But are not all the necessary directions given? Do they not all concern well-known tools capable of producing well-known effects, and are they not combined precisely as Messrs Gaulard and Gibbs combine them? Mr. Aston's answer is that the secondary regenerator was employed to alter the tension, not by diminution, but by increase, not by stepping down, to adopt his favorite expression, but by stepping up. This may be true, but it was common knowledge that an induction coil might be used for alternation in either direction, and the application of it in one way instead of the other cannot be deemed invention. Again, Messrs. Gaulard and Gibbs' patent may have taught the electrical world for the first time that high tension in the primary wire is essential to successful work—in other words, that they have discovered that the best, if not the only useful mode of using the dynamo for electric lighting is by the creation of high tension. If so, they are entitled to credit for having first seen what other laborers in the same field have failed to see; but ascertaining the best use of a known tool does not fall within the proper definition of invention. The reasons which have prompted me to dispose of this case at once on the point on which I have come to a definite conclusion, and not further to consider those requiring further consideration if my judgment were to be rested on them, render it also unnecessary to deal with the question of utility, but on that I have formed a definite opinion, and it is better that I express it. Having regard to the great and rapid advance made in this particular branch of science during the last few years, one would expect an invention of 1882 to have been ere this improved upon, if not superseded, and it is not surprising, nor is it any discredit to Messrs. Gaulard and Gibbs' ingenuity, to hear that arrangements on the parallel system are found to be far more effective than those on the series system adopted by the patentees. The evidence indicated, if it did not prove, that the latter would soon give way, if it has not already given way to the former. On the other hand, I have sufficient evidence that the series system has been successful—not only tried but used and found to work with at least a large measure of success. If, therefore, I could hold the patent to be good on other ground I certainly should not hold it to be bad on the point of utility. For the reasons which I have given I am of opinion that what Messrs. Gaulard and Gibbs describe in their amended specification as their invention, and for which they claim a monopoly, is not the proper subject-matter of a patent, that, therefore, the patent granted to them ought to be revoked, and I must make an order for revocation as asked by the petitioner. The respondents must pay the costs, to be taxed on the higher scale.

ELECTRIC RAILWAY PATENTS.

S. D. Field awarded priority of Green, Hall and Siemens, by the Examiner of Interferences.

On June 23d last, the examiner of interferences of the patent office rendered a decision in the cases that had been pending several years between Green, Hall, Siemens and Field, involving the issue defined as follows:—

"The combination of a stationary dynamo-electric generator driven by a suitable motor, a circuit of conductors composed in part of an insulated or detached section of the line of rails of a railroad track, a wheeled vehicle movable upon or along said section of track, an electro-magnetic motor mounted upon said vehicle for propelling the same, and included in said circuit of conductors, and a circuit controlling device placed upon said vehicle."

The decision awards priority to Mr. Field, after a full discussion of the evidence submitted in the case.

Green, whose application was filed May 15, 1886, alleges that he conceived the invention prior to 1875, that he disclosed it to others and constructed an experimental railway in that year; using a battery as a source of electricity, and that he made a larger railway in 1876. His road of 1875 was 200 feet long, the rails were of strap iron insulated, upon timber string pieces, the car carrying a motor receiving current "through the track wheels by a wire to said motor," the wheels being insulated from the axle and the car carrying a current reverser.

Reviewing the testimony in support of Green's case, the examiner says: "It is very evident that there is nothing in the testimony * * * evidencing a full disclosure of the invention in issue." "It appears, however, that he suggested to some of his witnesses that a dynamo might be used instead of a battery, but his invention in this particular amounted to nothing more than a suggestion or mere speculation," and again: "As Green did not reduce the invention to practice prior to Field and as it is not satisfactorily shown by competent and reliable evidence, that he was first to conceive the invention, no question of diligence arises, and his case may be dismissed at this point."

Hall dates his conception of the invention in 1848, and his disclosure and reduction to practice in 1849. His application was filed July 22, 1885. He amended his date of completion to 1856. The examiner says, in respect to Hall's testimony, "It may be stated as proven that in 1848 or 1849 he made and operated the toy railroad * * * and that he exhibited the same at the fair of the Charitable Mechanics' Association of Boston in 1850. In these experiments he used a battery connected to the track rails for the purpose of supplying the current to the motor on the wheeled vehicle. This model or toy railway, it appears, contained the essential elements of the issue except the dynamo-electric generator."

The examiner was satisfied, further, that between 1856 and 1860 Hall made some experiments in the use of a magneto-electric machine to run an electric railway, but dismisses any claim to priority based on such experiments in the following language:—

"Although an electrical engineer engaged in the manufacture of electrical apparatus, he seems to have done nothing for many years, after making the models, toward perfecting and adapting the invention for practical use, and he neglected to perfect his right by applying for a patent, because, as he says, having had a wretched experience in connection with patents previously obtained on account of infringements, he considered this invention too much for him to handle, and wanted others to help him, as he knew there would be litigation about it. * * * It would appear that his present activity is due to the fact that others have interested themselves in the matter, apprised him of his neglect, and spurred him on in making an application." The examiner limits Hall to the date of his application, viz., July 22, 1885.

In respect to the Siemens application, filed October 25, 1884, it was held that from the testimony, and under the rules of the patent office in respect to foreign inventions, no date earlier than July 28, 1879, could be maintained.

OBITUARY.

Hiram Sibley.

Hiram Sibley, whose name will be ever memorable in the annals of American telegraphy, died at his home in Rochester, N. Y., July 12, at the age of 81 years.

Mr. Sibley became interested in the introduction of the House printing telegraph about 1850, and soon became a leader in the commercial development of the telegraphic art generally. His faith and foresight, his courage and persistency, his forecast of the methods requisite to place the business of telegraphy upon a broad and comprehensive basis, suited to the needs of the country at large, led to the initiation of the series of consolidations of competing interests that culminated in the organization of the present Western Union Telegraph Co, in 1866, by the absorption of the American and United States companies, the only considerable rivals of the old Western Union.

Mr. Sibley was born at North Adams, Mass., in 1807. His early education was only such as the country schools of the period could supply, and his first employment was at shoemaking. He afterwards opened a machine shop, in which he was successful enough to accumulate a small capital during 10 years work, at the end of which he removed to Rochester, where he entered into business as a banker. The new art of telegraphy attracted his attention from its earliest days, and he was one of the supporters of Professor Morse in his application to Congress for the appropriation to build the experimental line from Washington to Baltimore. Having acquired an interest in the House patents, and taken a leading part in the organization of the New York and Mississippi Telegraph Co. in 1851,—which formed but one of a considerable number of connecting or competing lines—he soon perceived the inherent defects, the results of which manifested themselves in the balance sheets, of such a conglomerate system—or no system, of telegraphic service—and set on foot measures for consolidations of interests and more comprehensive organization and management. His broad and far-reaching views met with discouragement or ridicule at the hands of many of his associates, but they ultimately prevailed; with what results, both of fortune to those who joined the movement in time, and of public benefit to the country in unifying and systematizing the general telegraph service, is well known to all observers. It is unnecessary here to recite the various steps through which one and

another small or large company was brought into line. The prominent part taken by Mr. Sibley in the complicated and delicate negotiations is sufficiently attested by the fact, that upon the consummation of the great consolidations of 1866, the old Rochester party of directors came out at the head of the combined companies, and that Mr. Sibley's associate and coadjutor, Mr. J. H. Wade, became the first president of the gigantic corporation thus created.

Perhaps the most characteristic piece of work achieved by Mr. Sibley, was the construction of the line to the Pacific, which he undertook in 1861. Surprising as it may now seem, the project was derided by his associates, whose want of faith compelled him to apply to the government for assistance. Objections and difficulties were met on every hand, but he succeeded in getting a subsidy for 10 years, of $40,000 annually, and began the work of construction July 4, 1861, completing the line on the 15th of November following. Mr. Sibley may be said to have carried this work out single handed, and in no part of his career did he exhibit more of his peculiar boldness and energy. He well merited the public applause which greeted his success. In Reid's "The Telegraph in America," Mr. Sibley's characteristic business qualities are felicitously described as follows:—"Mr. Sibley had large, quick broad ideas, was a splendid pioneer, had a sublime contempt for obstacles. * * * When he started on a crusade, like the Israelites of old, he blew his horn lustily until the walls fell; and took a complacent toot after they were down."

Mr. Sibley was generous in gifts to Cornell and Rochester universities. He provided for the erection of Sibley College of Mechanic Arts at the former, and for the library building of the latter. By will he left an endownent fund for an additional professorship at Cornell. His successful business life yielded him a large fortune and made him a power in the world; but he never lost sight of the true value of knowledge and of manual skill, regarding them—to use his own words (quoted in an obituary by the *Western Electrician*)—as "two most valuable possessions, which no search warrant can get at, which no execution can take away, and which no reverse of fortune can destroy."

MR. BROWN AND THE DOG.—A BALLAD.

Suggested by the Proceedings at Columbia College, July 30, 1888.

Then Brown he read a paper, and he demonstrated there,
That alternating arguments were exceedingly unfair.
No company employed him, and his motives he felt sure,
Were thoroughly unbiased, philanthropic, and most pure.

He had read with deepest feeling that lives were sacrificed,
And in order to prevent this, new rules he had devised.
At once, as he expected, there arose a fearful din;
And the alternating advocates hurled weighty papers in.

He took refuge in Virginia, until the sky was clear,
And after slaying sundry dogs, he shouted, "I am here."
He was a most persistent man, this modest Mr. Brown,
And labored every night and day, to save our mighty town.

To prove that he was honest, his "plant" was all in view,
And he called from out the audience three men, all good and true.
One man was set to measure ohms, another watched the volts,
The third to watch the other two, and carefully take notes.

The dog stood in the latticed box,
The wires around him led;
He knew not that electric shocks
So soon would strike him dead.

"One hundred volts we'll give him now,"
The dog did not despair;
Brown wiped the sweat from off his brow;
The dog turned not a hair.

"Two hundred more," then Brown, he cried,
The dog did not complain:
He knew not that his friends had died,—
That he must die in vain.

At last there came a deadly bolt;
The dog, O where was he?
Three hundred alternating volts
Had burst his visceræ.

EPITAPH.

Every dog must have his day;
He had his and passed away.
He never drained life's bitter cup,
Death took him when he was a pup.

THE CUSHMAN TELEPHONE SUIT.

A DECISION IN FAVOR OF THE BELL COMPANY.

Judge Blodgett handed down his decision in the suit of the American Bell Telephone Company et al., against the American Cushman Company and others, July 20, finding in favor of the plaintiffs at all points. The opinion was a long one and reviewed the testimony clearly and concisely.

The court entered an interlocutory decree, declaring the Bell patents valid and the exclusive property of the complainant company. The defendants were declared to have infringed upon these patents, and it was ordered that the complainants should recover of the defendants the profits made by them by reason of their infringement and damages sustained by such infringement. A reference to Master in Chancery, E. B. Sherman, was ordered to ascertain and report the amount of damages. Finally, the court granted a perpetual injunction against the defendants, restraining them from any futher infringement on the complainants' patents, and ordered them to pay the costs of the suit.

The Indiana company was also enjoined from opening any more exchanges or extending its business.

ELECTRIC STREET RAILWAYS IN AMERICA

Now in Operation.

ABBREVIATIONS.—**mi.**, miles of single track; **g.**, gauge; **lb.**, pounds rail per yard; **m.**, electric motors; **c.**, cars; **m. c.**, motor-cars; **h. p.**, horsepower; **T.**, T rail. Name of electric system used is in SMALL CAPITALS.

St. Catherines, Ont.—St. Catherine's, Merritton & Thorold St. Ry. Co.—*Pr.*, E. A. Smyth; *Sec.*, A. P. Friesman; *Supt.*, R. McMaugh; *Eng.*, W. S. Smith; 5.75 mi.; g. 4-8½; 30 lb.; 4c.; 12 m. c.; sta. 400 h. p. (water power); overhead cond. VAN DEPOELE.

St. Joseph, Mo.—Union Ry. Co.—*Pr.*, Seymour Jenkins; *Sec.* and *Tr.*, A. Steinacker; *Supt.*, Chas. Wilson; 9½ mi.; g. 4-8½; 35 lb.; 8 m. c.; overhead cond. SPRAGUE.

Scranton, Pa.—Scr. Suburban Ry. Co.—*Pr.*, Edw. B. Sturges; *Sec.*, G. Sanderson; *Tr.* T. F. Torrey; *Supt.* and *G. M.*. B. T. Killam; *Eng.*, J. Nazel; 4.5 mi.; g. 4-8½; 35, 40 and 52 lb.; 14 m. c.; sta. 300 h. p.; overhead cond. THOMSON-HOUSTON.

Wheeling, W. Va.—Wheeling Ry. Co.—*Pr.*, Jno. Spiedel; *Sec.*, Jno. M. Sweeney; 5.25 mi.; g. 5-2; 45 lb.; 12 m. c.; sta. 240 h. p.; overhead cond. THOMSON-HOUSTON.

Wilkesbarre, Pa.—Wilkesbarre & Suburban St. Ry. Co.—*Pr.*, H. H. Sen; *Sec.*, W. E. Shupp; *Tr.*, C. Walter; *Supt.*, A. C. Robertson; 3·6 mi.; g. 5-2; 50 lb.; 3 m. c.; sta. 120 h. p.; overhead cond. SPRAGUE.

Wilmington, Del.—Front & Union St. Ry. Co.—*Pr.*, G. W. Bush; *Supt.*, S. A. Price; *Tr.*, E. T. Taylor; g, 5-2; —— lb. SPRAGUE

Windsor, Ont.—Windsor Elect. St. Ry. Co.—*Pr.*, W. M. Boomer; *Sec.*, A. H. Joseph; *Supt.* W. C. Turner; *G. M.*, P. C. Ponting; 1.5 mi.; g. 3-6; 25 lb.; 1 c.; 1 m. c.; sta. 20 h. p.; overhead cond. VAN DEPOELE.

Woonsocket, R. I.—Woonsocket, St. Ry. Co.—*Pr.*, Horace H. Jenckes; *Sec.* and *Eng.*, Willard Kent; 1 mi.; g. 4-8½; 25 and 50 lb. T; 1 m. c.; sta. 1,000 h. p.; overhead cond. THOMSON-HOUSTON.

Constructing or Under Contract.

Attleboro, Mass.—Att., N. Attleboro & Wrentham St. Ry. Co.—*Pr.*, H. G. Bacon; *Tr.*, J. E. Draper; *G. M.*, H. M. Daggert, Jr.; 6 mi.; g. —— lb.; —— c.; —— m.; sta. —— h. p.; overhead cond.
Boston, Mass.—West End Ry. Co.—12 mi.; 20 m. c.; overhead. SPRAGUE.
Brockton, Mass.—East Side St. Ry. Co.—*Pr.*, A. F. Small; *Clerk*, C. A. Noyes; *Tr.*, C. D. Fullerton; *Eng.*, E. L. Brown; 4½ mi.; g. 4-8½; 40 lb.; 4 m. c.; steam-power sta. 60 h. p.; overhead cond. SPRAGUE.
Buffalo, N. Y.—Citizen's Elect. Ry. Co.—*Pr.*, A. P. Wright; *Sec.*, F. F. Fargo.
Chattanooga, Tenn.—Chat. Elect. St. Ry. Co.—*Pr.*, C. A. Lyerly; *Sec.*, C. E. Scott; *Tr.*, C. V. Brown; *G. M.*, E. Scott; 4 mi.; g. 4-8½; 25 lb.
Cleveland, O.—— —— 8 mi.; 16 m. c.; overhead. SPRAGUE.
Cincinnati, O.—Mt. Adams and Eden Park Inclined Ry. Co.—*Pr.*, Geo. B. Kerper; *Sec.*, J. R. Murdock; *Tr.* and *G. M.*, G. B. Kerper; *Supt.*, R. Palley; *Eng.*, H. Kolf; 1 mi.; g. 5-2½; 52 lb.; 3 m. c.; 3 m. overhead.
Davenport, Iowa.—3.5 mi.; 8 m. c.; overhead cond. SPRAGUE.
Dayton, O.—White Line St. R. R. Co.—*Pr.* John A. McMahon; *Sec.* Chas. D. Iddings; *Treas.* Michael A. Nipgen; 8.5 mi.; g. 4-8½; 38 lb.; 16 c.; 3 m. c.; sta. 240 h. p.; overhead and conduit cond. THOMSON HOUSTON.
Elsinore, Cal.—Elsinore Lake Shore Elect. Ry. Co.—*Pr.*, D. G Dexter; *Sec.* and *Manager*, H. L. Courad; *Tr.*, F. H. Heald.
Erie, Pa.—Erie City Pass. R. R. Co.—*Pr.*, W. W. Reed; *Sec.*, J. L. Sternberg; *Supt.*, Jacob Borst.
Flushing, N. Y.—Flushing & College Point St. R. R.—*Pr.*, J. Dykes; *Sec.*, Charles Frey; *Tr.*, Henry Clement; g. 4-8½; 45 lb.; 1 mi.; storage bat's.
Harrisburg, Pa.—East Harrisburg Pass. Ry. Co.—4.5 mi.; g. 5.2½; 52 lbs.; sta. 160 h. p.; 6 m. c.; overhead cond. SPRAGUE.
Lakeside, O.—3 mi.; 2 c.; overhead cond.
Lincoln, Neb.—Lincoln Cable Ry. Co.—*Pr.*, J. H. Ames; *Sec.*, L. Coon; 5 mi.; g. 4-8½; 56 lb.; 10 m. c.; storage bats.
Louisville, Ky.—Central Pass. R. R. Co.—*Pr.*, B. du Pont; *Sec.*, J. C. Donigan; —— mi: g. 5.
Meriden, Conn.—Meriden Horse R.R. Co.—*Pr.*, Geo. R. Curtis; *Sec.* and *Tr.*, C. L. Rockwell; *Supt.*, D. Barker; 5 mi.; g. 4-8; 35 lb.; 12 m. c. DAFT.
Newton, Mass.—Newton St. Ry. Co.—*Pr.*, H. B. Parker; *V. P.*, Joseph W. Stover; *Sec.* and *Treas.*, H. C. Pratt (office, Newtonville, Mass); 6 mi.; g. 4-8½; 52 lb.
New York, N. Y.—N. Y. & Harlem (Fourth Avenue) R. R. Co.—*Pr.*, C. Vanderbilt; *Sec.* and *Treas.*. E. V. W. Rossiter; *Supt.*, Alfred Skitt; 18½ mi.; g. 4-8½; 60 and 75 lb.; 10 m. c.; storage bats. JULIEN.
New York, N. Y.—North & East River Ry. Co.—*Pr.*, W. W. Laman; 1 mi.; g. 4-8½; conduit conductor. BENTLEY-KNIGHT.
Omaha, Neb.—Omaha Motor Ry. Co.—*Pr.*, Dr. S. D. Mercer; *Sec.*, J. T. Hertzman; *Treas.*, S. S. Curtis; 5 mi.; g. 4-8½; 56 lb.; 20 m. c.; sta. 250 h. p.; overhead cond. VAN DEPOELE.
Ontario, Cal.—Ontario & San Antonio Heights Ry. Co.—*Pr.*, Chas. Frankish; *Sec.* and *Treas.*, D. McFarland; 8 mi.; g. 4-8½; 34 lb.; 4 c.; 3 m.; overhead cond. DAFT.
Philadelphia, Pa.—Lehigh Ave. Ry. Co.—*Pr.*, J. T. Banting; *Sec.* and *Treas.*, J. McK. Barron; 6 mi.; g. 5-2½; 47 lb.; storage.
Port Chester, N. Y.—P. C. & Rye Beach St. Ry. Co.—*Pr.*, F. H. Skeele; *Sec.*, E. H. Cook; *Tr.*, C. D. Newton; *V. P.*, M. Dillon; *Supt.*, T. M. Burt; 3 mi.; g. 4-8½; 38 lb.; 5 m. c.; overhead DAFT.
Revere, Mass.—Lynn & Boston R. R.—Ocean Ave. line; overhead cond. THOMSON-HOUSTON.
Rochester, N. Y.—Rochester Elect. Ry.—*Pr.*, A. T. Soule; *Sec.*, J. B. Perkins; 9 mi.; 4-8½; 40 lb.; 20 c.; 8 m.
St. Louis, Mo.—Lindell Ry. Co.—*Pr.*, J. H. Lightner; *Supt.*, G. W. Baumhoff; *Eng.*, E. J. Bagnall; —— mi.; g. 4-10; 65 lb.; 1 m. c.; 2 m.; 3 p. c.; storage bats.
Sacramento, Cal.—Sac. Elect. Ry. Co. The Central Street Railway Co.—*Pr.*, L. L. Lewis; *Sec.*, E. K. Alsip; *Tr.*, F. Miller; *Supt.*, J. B. Austin; *Eng.*, ——; 13 mi.; g., 4-8½. Cars to be supplied by Electric Car Co, of America, Philadelphia.
Salem, Mass.—Naumkeag St. Ry. Co.—*Pr.*, C. Odell; *Tr.*, H. Wheatland; *Sec.*, J. F. Hickey; *Supt.*, W. B. Furgurson; 1½ mi.; g. 4-8½; 6 m. c.; 35 lb.; 80 p. c.; sta. 100 h. p.; overhead cond. SPRAGUE.
Sault Ste. Marie, Mich.—S. St. M. St. Ry. Co.—*Pr.*, E. M. Lacy; *Sec.*, F. Ryan; *G. M.*, L. G. Cody; 2 mi. FISHER.
Scranton, Pa.—The Nayaug Crosstown R. R. Co.—*Pr.*, E. B. Sturges; *Sec.*, A. Frothingham; *Tr.*, G. A. Jessup; *Supt.* and *Eng.*, T. Gibbs; 1-5 mi.; 4-8½; 52 lb.; 2 m. c.; steam power; sta. 250 h. p.; overhead cond. VAN DEPOELE.
Scranton, Pa.—The People's St. Ry.; overhead. SPRAGUE.
South St. Paul, Minn.—So. St. Paul Rapid Transit Co.—*Pr.*, A. E. Clark; *Sec.* and *G. M.*, J. H. Lawrence; 8 mi. (Enos elevated railway); 40 and 56 lb.; 10 m. c.; track conductors. DAFT.
Springfield, Mo.—2 mi. FISHER.
Sunbury, Pa.—Sun. & Northumberland St. Ry. Co.—*Pr.*, H. E. Davis; *Sec.*, L. H. Kase; *Tr.*, S. P. Wolverton; 3 mi.; 4 c.; overhead cond.
Syracuse, N. Y.—Third Ward Ry. Co.—*Pr.*, Wm. B. Cogswell; *Sec.* and *Treas.*, W. S. Wales; *G. M.*, H. McGonegal; 4 mi.; g. 4-8½; 8 m. c.; 4 p. c.; steam power; sta. 250 h. p.; overhead cond. THOMSON-HOUSTON.
Worcester, Mass.—Worc. & Shrewsbury—(To be changed from steam to electricity); 2.7 mi.; g. 3; overhead cond. DAFT.

Notes.

WILMINGTON, DEL.—Mr. Wm. Canby, president of the Wilmington City R. W. Co., whose electric road (Sprague) with overhead conductors has now been in operation over four months, expresses his entire satisfaction, endorsed by the board of directors, with the results, both practically and financially. Mr. Canby says:—"We consider it by all odds the best and most economical mode of running street cars in suburban districts, or in any place where permission to erect poles can be obtained. In comparison with horse-power, we find it decidedly cheaper and more efficient in every way."

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From June 19 to July 17, 1888 (inclusive).

Alarms and Signals:—*Electric Fire Apparatus*, G. M. Stevens, 384,875, June 19. *Electric Signal Transmitter*, W. C. Thompson, 385,388, July 3. *Electrical Annunciator*, M. M. Wood, 385,894, July 10. *Police Signal Apparatus*, J. C. Wilson, 386,175. *Electrical Bulletin*, P. B. Delany, 386,189, July 17.

Clocks:—*Secondary Electric Clock Movement*, C. Bohmeyer, 386,108, July 17.

Conductors, Insulators, Supports and Systems:—*Insulated Conductor*, C. C. Sibley, 385,576, July 3. *Electric Conductor*, L. Daft, 385,915, July 10. *Electric Wire Insulator*, H. H. Cutler, 386,111, July 17.

Distribution:—*System of Electrical Distribution*, T. A. Edison, 385,173, June 26. *Electrical Distribution by Storage Batteries*, G. W. Walker, 386,225, July 17.

Dynamos and Motors:—*Dynamo-Electric Machine*, R. Oliver, 384,688. *Commutator for Dynamo-Electric Machines*, J. J. Wood, 384,816, June 19. *Dynamo-Electric Machinery*, A. Reckenzaun, 385,068, June 26. *Dynamo-Electric Machine*, A. Harding, 385,458. *Electric Motor and Dynamo-Machine*, O. Lugo, 385,675, July 3. *Commutator for Dynamo-Electric Machines*, F. B. Mitchell, 385,943. *Magneto-Electric Machine*, W. Humans, 386,071, July 10. *Dynamo-Electric Machinery*, G. Miot, 386,340, July 17.

Galvanic Batteries:—*Galvanic Battery*, C. A. Brown and M. M. Clark, 384,958. *Electrolyte for Galvanic Batteries*, B. J. Wheelock, 385,028. *Galvanic Battery*, E. E. Starr, 385,147. *Battery Zinc*, J. Doyle, 385,254. *Electric Battery*, E. M. Hewett, 385,308, June 26. *Porous Cup for Galvanic Batteries*, A. K. Eaton, 385,344, July 3. *Electric Battery*, W. P. Kookogey, 385,760. *Electric Battery*, I. L. Roberts, 386,090, July 10. *Galvanic Battery*, A. V. Meserole, 386,149 and 386,150, July 17.

Ignition:—*Magneto-Electric Fuse*, E. L. Zalinski, 384,662. *Electric Gas-Lighting Device and Gas Cock*, W. Tag and S. C. Smith, 384,796, June 19. *Method of Blasting*, M. Widdell, 386,281, July 17.

Lamps and Appurtenances:—*Incandescent Lamp Socket and Switch*, J. J. Wood, 384,815. *Electric Arc Lamp*, J. J. Wood, 384,817, June 19. *Electric Light System*, B. E. Sunny, 385,020. *Holder for Incandescent Lamps*, W. A. Carey, 385,039, June 26. *Electric Lamp Socket*, J. S. Adams and A. W. Morrell, 385,436. *Suspension Arm for Electric Lamps*, J. J. Wood, 385,498, July 3. *Arc Lamp*, J. E. Gaston, 385,705. *Automatic Cut-Out for Incandescent Lamps*, M. J. Wightman and H. Lemp, 386,099, July 10.

Measurement:—*Electric Meter*, E. Thomson, 385,647, July 3.

Medical and Surgical:—*Medicated Electric Belt*, C. U. Hoke, 385,556, July 3.

Metallurgical:—*Magnetic Separator*, M. H. Smith, 384,645, June 19. *Sluice Box*, J. H. Rae, 386,030, July 10.

Miscellaneous:—*Electro-Magnetic Parcel Carrier*, M. C. Mengis, 384,775. *Rack for Electroplating*, W. W. White, 384,806. *Electro-Magnetic Time Lock*, C. J. Kintner, 384,856. *Electric Stopping Mechanism for Looms*, E. A. Smith, 384,934, June 19. *Rheostat*, J. W. Packard, 385,001. *Apparatus for Electric Welding*, E. Thomson, 385,022. *Electric Switch*, P. J. Tracy, 385,023. *Switch for Electrical Purposes*, W. A. Carey, 385,041. *Mariner's Recording Compass*, H. A. Chase, 385,042. *Electric Alarm Compass*, same, 385,043. *Electric Cut-Out*, C. G. Perkins, 385,067. *Lightning Escape for Wire Fences*, A. Cockrell, 385,095. *Method of Generating Electricity and Purifying Water*, J. E. Siebel, 385,145. *Electrical Pumping Apparatus*, F. J. Sprague. 385,211. *Steering Apparatus for Vessels*, B. A. Fiske, 385,259. *Electro-Magnetic Dental Hammer and Plugger*, P. Helmer, re issue, 10,940, June 26. *Method of Joining Pipes by Electricity*, E. Thomson, 385,384. *Method of Electrically Welding Chains and Links*, E. Thomson, 385,385. *Direct Electric Welding Machine*, E. Thomson, 385,386. *Cut-Out*, C. D. Wright, 385,494. *Relief Die and Process of Making the Same*, G. F. and J. W. McIndoe, 385,519. *Electric Switch*, E. F. Bergman, 385,539. *Electro-Mechanical Type-Writer*, J. F. McLaughlin, 385,565, July 3. *Protector for Electrical Instruments*, G. W. and W. Mingle, 385,770. *Electric Switch*, S. S. Wheeler, 385,782. *Electrical Switch*, J. E. Mayo, 385,815. *Graphophone*, C. S. Taintor, 385,886. *Graphophonic Tablet*, C. S. Taintor, 385,887. *Automatic Weighing and Recording Apparatus*, E. H. Amet, 385,900. *Coin Operated Induction Coil*, J. W. Hazell, 385,927. *Apparatus for Tilling Ground*, E. R. Whitney, 385,984. *Electric Lock*, F. J. Gridley, 386,066. *Method of Welding by Electricity*, E. E. Ries, 386,068, July 10. *Apparatus for Electric Welding*, E. Thomson, 386,441. *Electrical Conductor*, E. Weston, re-issues, 10,944, July 17, same, 10,945.

Railways and Appliances:—*Automatic Electric Gas Cut-Off for Railroad Cars*, F. C. Brower, 384,676. *Electric Railway*, S. D. Field, 384,685. *Automatic Electric Block-Signal System*, T. D. Williams and J. S. Lucock, 384,810. *Apparatus for Operating Automatic Block Signals*, same, 384,811. *Railway Signaling*, T. A. Edison and E. T. Gilliland, 384,830. *Guard Rail and Insulator for Electric Railways*, H. A. Foster, 384,901. *Electric Railway*, R. M. Hunter, 384,908, 384,909, 384,910, 384,911 and 384,912, June 19. *Electric Railway Signal*, S. C. C. Currie, 384,962. *Electromotive Railway*, G. T. Woods. 385,034. *Electric Railway*, R. M. Hunter, 385,053, 385,054 and 385,055. *Electric Railway*, G. H. Condict, 385,097. *Electric Railway*, R. M. Hunter, 385,180. *Electrical Connector*, F. Stitzel and C. Weinedel, 385,215, June 26. *Switch Signal*, A. F. Martel, 385,363. *Current Collector for Series Electric Railways*, S. H. Short, 385,379. *Electric Railway Power and Lighting Appliance*, I. W. Heysinger, 385,413. *Device for Securing Wire to Railroad Rails*, F. Stitzel and C. Weinedel, 385,484. *Electric Railway*, R. M. Hunter, 385,672. *Railway Signal*, A. F. Martel, 385,677, July 3. *Electric Motor for Street Cars*, W. S. Salisbury, 385,727. *Device for Lighting and Heating Cars by Electricity*, De Witt C. Roberts, 385,774. *Electric Railway System*, E. M. Bentley. 385,787. *Railway Signal Lantern*, C. H. Peters, 385,877. *Electric Railway*, E. M. Bentley, 385,902. *Switch on Overhead Lines in Electric Railways*, E. M. Bentley, 385,903. *Railway Signal*, C. F. DeRedon, 385,920. *Electric Railway*, E. W. Heald. 385,928. *Electric Signal for Railways*, E. A. Sharp, 385,964. *Railway Signal*, G. H. Wright, 386,049. *Electric Railway*, E. E. Ries, 386,085. *Driving Mechanism for Electric Railway Cars*, E. E. Ries, 386,086. *Combined Electric Railway and Wire Conduit*, E. E. Ries, 386,087, July 10. *Electric Railway*, R. A. Chesebrough, 386,184. *Tunnel Construction for Electric Railways*, G. T. Woods, 386,282, July 17.

Storage Batteries:—*Secondary Battery*, A. Reckenzaun, 385,200, June 26. *Secondary or Storage Electric Battery*, S. L. Trippe, 385,390. *Secondary Battery*, F. King, 385,558, July 3.

Telegraphs:—*Telegraph Relay*, F. Stitzel and C. Weinedel, 385,214, June 26. *Telegraphic Recording Apparatus*, C. Cuttriss, 386,059, July 10. *Automatic Telegraph Transmitter*, Z. P. Hotchkiss, 386,129, July 17.

Telephones, Systems and Appliances:—*Multiple Switch-Board Testing Apparatus*, C. E. Scribner, 384,614, June 19. *Test System for Multiple Switch-Boards*, C. E. Scribner, 385,205, June 26. *Combined Speaking and Signaling Apparatus*, J. E. Kelly, 385,357. *Test Signal Circuit*, C. E. Scribner, 385,482. *Spring-Jack Switch*, C. E. Scribner, 385,528. *Telephone Transmitter*, J. Emmner, Jr., 385,664, July 3. *Multiple Switch-Board*, A. Sechrist, 385,826. *Mechanical Telephone*, L. D. Brear, 385,839. *Wiring Switch-Boards*, J. A. and F. B. Cook, 385,846. *Multiple Switch-Board*, M. G. Kellogg, 385,863. *Electric Telephone*, N. Parks, 385,956. *Telephone Central Station Apparatus*, T. N. Vail and J. A. Seely, 385,974, 385,976 and 385,977. *Telephone Sub-Station Apparatus*, same, 385,975. *Telephone Exchange Signaling*, same, 385,978, July 10. *Mechanical Telephone*, F. E. Clarke, 386,238. *Telephone Transmitter*, C. W. Brown, 386,380, July 17.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VII. NEW YORK, SEPTEMBER, 1888. No. 81

ELECTRIC LIGHT COMPETITION.

COMMENTING upon the situation of the electric lighting industry two years ago, THE ELECTRICAL ENGINEER, of August, 1886, used the following language: "At present there is apparently not sufficient control of fundamental features of arc or incandescent lamps, or of dynamos, by virtue of patented inventions, in the hands of any single interest or combination, to justify any material taxation of the business of lighting in the way of royalty." The exaction of royalties, whether in the form of stock in local companies or otherwise, had then well nigh, if not entirely, been discontinued, and business in electric light machinery and supplies has since been conducted under conditions of strenuous competition by both arc and incandescent companies. While inventors have increased in numbers and activity on all sides, and the various electric light companies have been eager to secure patents upon improvements in their art, the bulk of the business has been transacted with small regard to patent questions. Purchasers of plant have confined their attention for the most part to the quality and cost of an outfit; the best and cheapest being sought, with little if any regard to possible patent complications.

During the past two years the interest in patent questions of the companies manufacturing electric light plant has been shifted chiefly to inventions in methods of distribution, and has largely centered in the alternating current and transformer method. The Gaulard and Gibbs' American patent on this system has met with a rebuff in its first encounter with opponents in court, whatever its ultimate success or failure may be. But successful distribution by alternating currents involves a number of problems quite beyond and in addition to the general principle of the Gaulard and Gibbs' patent, problems that are attacked with varying degrees of success by the several companies that have ventured into the new field; and for some time to come there will be energetic competition for business between them unless the strain lead to a combination of interests at an early day. The latter contingency seems not unlikely, as we recently said in these columns. We would not like to see an Electric Light Trust established, after the manner of some of the great combines of the day, nor do we imagine that such a thing is likely to come about; but the conditions under which the business is carried on at this time, the severity of competition, and the throwing open to general use, temporarily or permanently, through decisions of the courts in patent suits, of several inventions that have been regarded as fundamental, seem favorable to the establishment of greater community of interests than now exists among the leading companies.

In view of what has happened in analogous enterprises the present tension and uncertainty of their mutual relations would seem to suggest with much force to leading companies the policy of consolidation or coalition.

Meantime there is no complaint of any lack of business. Central station incandescent work has had a remarkable impetus since the advent of alternate current distribution some two years ago; and there can remain no doubt of the permanent value of that system for widely extended districts. Perhaps the best proof of its great utility is found in the number of electric companies that have committed themselves to its employment.

THE ELECTRIC LIGHT ASSOCIATION.

As we go to press with our September number the National Electric Light Association will be engaged in the early sessions of its semi-annual meeting, August 29–31, at the Hotel Brunswick, New York. Papers are expected to be read as follows:—Dr. Louis Duncan, of Johns Hopkins University, relating to tests made by himself and his associates; Professor E. L. Nichols, of Cornell University, subject not announced; O. B. Shallenberger, "Measurement of Alternating Currents for Commercial Purposes;" E. G. Acheson, "Disruptive Discharges in Underground Conductors;" C. C. Haskins, "Some Practical Pointers;" S. S. Wheeler, "Electric Conductors in New York;" F, B. Crocker, "The Ideal Motor;" Wm. Lee Church, "Electrical Steam Engineering;" Dr. Leonard Waldo, subject not announced.

Among other important business to come before the convention will be a revision of the constitution of the association, a committee having been appointed at the Pittsburgh meeting in February last to prepare amendments and to report them at the August meeting. In this connection we take the liberty of calling attention to the possible, or in our opinion probable, desirability of dispensing with the semi-annual meetings after the current year. The winter meetings have been better attended and of greater interest and usefulness than the semi-annual or summer conventions, and the association has now, it seems to us, acquired sufficient stability to be able to maintain its position and increase its usefulness with an annual meeting

only. The permanent secretary, together with the executive committee, can well preserve the continuity of the work of the association for a year. It seems extremely probable that the elimination of the semi-annual or summer meeting would result in an increase in attendance at the annual meeting and further accession of desirable memberships. There is plenty of time to think over the matter before the annual meeting next winter.

A complete report of the present convention, including all the papers read and their discussion will be published in an extra number of the ELECTRICAL ENGINEER soon after the adjournment of the association.

THE annual meeting of the National Telephone Exchange Association closely follows the Electric Light Convention, at the same hotel, New York city, assembling Tuesday, September 4, at 11 A. M. It is expected that two days will be devoted to business and a third to visits to points of interest in and near New York under the good offices of local members, to whose guidance members from a distance, on knowledge or pleasure bent, may confidently entrust their local travels.

UNDER the encouragement of the Electric Lighting Act of 1888, recently enacted by Parliament, which is more favorable to electric lighting interests than the Act of 1882, central station lighting is about to be undertaken in London on a large scale.

We are in receipt of the prospectus of the "Metropolitan Electric Supply Co., limited. Capital £500,000, in 50,000 shares of £10 each, being 49,900 ordinary shares and 100 fully paid founder's shares; to be increased from time to time as the works extend." Sir John Pender is chairman of the company, and the directory includes such well-known names as Sir George Elliot; Admiral Sir George H. Richards; Sir James Anderson; J. E. H. Gordon, Esq.; Henry Weaver, Esq., and others. The directors express their belief "that the time has arrived when the great work of electric lighting may be undertaken on a scale which will largely meet the requirements now supplied by gas, and that it can be established on a sound scientific and commercial basis." The company announces its purpose to construct works at once in the parishes of St. James, Westminster (Piccadilly), and St. Martin's-in-the-fields, districts embracing many of the principal hotels, clubs and theatres; and states that it has contracted to take over the undertaking of the Whitehall company, including their works now nearly completed. The prospectus states that "the company is not committed to any particular patents or systems, but is quite free to adopt any system which promises favorable results."

In justification of the expectation of commercial success the promoters of the London company quote the earnings of a considerable number of American electric lighting companies. While the authenticity of some of the figures given might be questioned, there is no doubt that well planned and carefully managed central station plants can and do yield good profits. The average of the figures quoted is large enough to permit a considerable abatement and still leave a satisfactory percentage.

THE opinion of Judge Colt, of the U. S. Circuit Court, Massachusetts, broadly upholding the Thomson-Houston regulator patent, printed in another column of this issue, constitutes, we believe, the first instance in which an important electric lighting patent has been sustained by a United States Court and declared to have been infringed. Considering the comprehensive character of the claim sustained in this decision, a considerable number of arc light companies will probably find themselves obliged to make terms with the Thomson-Houston company. Most, if not all, the automatic current regulators so freely used in arc lighting would seem to come under the terms of the Thomson-Houston claim. There seems to have prevailed a somewhat general impression that the patent could not be maintained in court.

MR. ANTHONY RECKENZAUN's series of articles on the Construction and Management of Storage Batteries in the *Telegraphic Journal and Electrical Review* of London, which was interrupted nearly a year ago, is now continued in that journal. Two installments of the resumed series are reprinted in the present number of the ELECTRICAL ENGINEER, continuing our reprint of the earlier papers. Mr. Reckenzaun makes liberal use of his experience and observations in America last summer and fall. His wide experience with storage batteries lends interest and value to his writings on the subject, particularly in view of the apparent uncertainty at the present time in respect to the ultimate value of accumulators in electrical distribution on a large scale.

THE Ohio Valley Centennial Exposition, at Cincinnati, to open September 4th, will comprise an extensive and varied exhibition of electric lighting. The outfits shown by the several companies exhibiting will be used in illuminating the grounds and buildings. Plants will in this way be shown in operation by the following companies:—The Western Electric Co., eight dynamos and 225 arc lamps; the Waterhouse Electric Co., eight dynamos and 230 arc lamps. Three thousand incandescent lamps, fed by six 500 light dynamos will be shown by the Edison, Queen City, and Mather companies, in equal portions. These lighting plants will be run by engines exhibited by the following companies:—The Buckeye Engine Co., of Salem, O., the Atlas Engine Co., of Indianapolis, Russell & Co., of Massillon, O., and the Ball Engine Co., of Erie, Pa. The Cincinnati Exposition promises to be of much interest as an industrial display.

AMONG the many rules suggested or adopted in various localities for the regulation of electric light circuits, the proposition of Mr. S. S. Wheeler that "an arc lamp within the reach of any man's umbrella is hung too low," is such an obviously common sense suggestion as to commend itself everywhere.

The writer of the communication on "Gravity Battery *vs.* Dynamos," signed D. S., in *Letters to the Editor*, ELECTRICAL ENGINEER for July, desires to correct an error in the eighth line from bottom of page 320, where "one volt and two amperes" should read one volt and two *ohms*.

OBSERVATIONS.

A GREAT many people now living have at one time or another experienced some kind of electric shock. John Tyndall tells how he was blotted out, on the lecture platform one evening, by receiving the combined discharge of a number of Leyden jars, and that on resuming his existence, he found that he had been absent from the body, so short a time that the audience had not noticed anything wrong; which gives color to the statement of Mahomet that he was taken from his bed, carried to the third heaven, and retained there for a long time, but that returning to his bed, he found it still warm. Circumstances have lately led the observer to enquire regarding the sensations of people who have received the violent shock of a dynamo current, *straight*. All whom he has been able to interrogate concur in stating that when sensation returned, it returned piecemeal as it were. Each had a decided impression that he was totally dismembered, that every member of his body was in a number of fragments, and that the several fragments in recovering from the shock, were gradually once more coming together; and that the several members were slowly getting into place. One man graphically described the anxiety with which he waited, with bated breath, and absolutely a fear to move, lest something should join itself to something else, wrong end to; and said he was especially afraid that his finger nails would come back with the outward end in, and become so fixed.

Who will rise and explain this? Perhaps it may be a phenomenon of the direct current only.

. . .

THE above was brought to mind by reflecting upon the dog experiments of Mr. Harold P. Brown, Electrical Engineer, *et al.* Is'nt it rather hard lines to be a dog in these scientific times? The proverb says "Every dog has his day," but it may well be imagined that if his day is to be an electric day he could easily be persuaded to forego it.

. . .

PASSING from types and shadows to symbols, and thinking once more of the same proverb,—are not the candle of Jablochkoff (that burglarious name) and its congeners, something like the dog in their evanescence? To be sure, the Jablochkoff, the Jamin and Wilde candles are now hard to find; they have been outshone and out-distanced by the regulating arc lamps, and now none are so poor as to do them honor; but who can or who would care to deny, that they have had their day, and a glorious day at that?

Was it not these candles first that made arc lighting a commercial success; showing that several arcs could be burned in series; and more than this, showing that the necessary thing for the long maintenance of light without attendance, was the initial provision of a number of pairs of carbons, and of an automatic contrivance for substituting the second and third pairs, as the prior ones were consumed; the pioneer thought of the double carbon mechanism lamps of the present day. All honor then to the candle, as having lighted us on the way to a more brilliant career of electric illumination.

. . .

TALKING and writing about the discovery of the electric arc light, we rightly ascribe it to Sir Humphrey Davy. But we nearly always give the date as 1809. It seems, however, that if Davy did not actually hit the bull's eye in 1800 and 1802, he got at least within the centre circle.

Nicholson's Journal, for October, 1800, contains a letter signed by Davy, which states that he has discovered that "well-burned charcoal possesses the same properties as metallic bodies in producing the shock and *spark when made a medium of communication between the ends of the galvanic pile of Signor Volta.*"

And in the *Journal of the Royal Institution*, vol. i., of 1802, Davy describes some experiments upon the sparks yielded by the voltaic pile, and states, "When instead of the metals, pieces of well-burned charcoal were employed, *the spark was still larger and of a vivid whiteness.*" One is inclined to think that this spark was a true arc as now understood.

PROBABLY nearly every electric arc lighting company owning a system (?) now electroplates its carbons. There was in the dark ages of 1879, an interference in our much abused patent office, between the two well-known inventors, Charles F. Brush and Moses G. Farmer, in relation to the coppering of electric light carbons, and it was held by Paine, Commissioner, that Farmer had invented the process in controversy, before Brush; but had also abandoned it, so that while priority was therefore awarded to Brush *pro forma*, the invention was thrown open to the public by Farmer's prior invention, and failure to patent.

But as a matter of fact Jablochkoff, had as early as 1876, plated the carbons of his candles with copper; and though the invention had prior to that time been patented in France by Reynier, Jablochkoff disdained to recognize the Reynier patent, depending upon prior patents and publications; and it appears that Jablochkoff was right, since the Reynier patent was subsequently voided by the French courts, and held to be anticipated by a prior Carré patent; and by Van Malderen's work in 1868. Bouliguine and Tchikoleff, also in Russia, plated their carbons, and published accounts of their practice.

The history of this feature of electric lighting is closely paralleled by many other features; and all other branches of applied electricity likewise disclose similar instances of anticipation. Electric lighting, however, is so old an art in itself, although commercially young, that inventors in this field cannot go far without running foul of something which had been invented (though very likely not much employed) years before.

And they acquire a decided impression, which they may voice, as others have done before them, in the complaint that "the people of *former times* had little honesty, they have stolen all my inventions."

. . .

ACCORDING to one of our New York E. C.'s., "San Diego, Cal. has adopted the Westing*home* system of incandescent lighting." To be sure; isn't an 'ouse, an 'ome?

. . .

AT a recent regular quarterly meeting of the New Englan Electric Exchange, Mr. Geo. F. Curtiss read an eloquent and able paper upon "Lightning Arresters." Mr. Curtiss, speaking of the telegraph switch-board lightning arrester, says: "All of these serve their purpose on lines of low potential, as for instance telephone, telegraph, fire alarm, etc." It is hardly fair to criticise adversely the only weak spot in an otherwise excellent paper, were it not in the general interest; it would, however, be interesting to know the process of reasoning whereby Mr. Curtiss reaches the conclusion that telephone lines carry currents of low potential, for that is probably what he means.

An electric current capable of passing through 12 persons, in series, each clasping hands with the person on either side, would, to the observer, even though he be but an ordinary one, seem to be very fairly equipped in the matter of potential.

. . .

THE Society of Telegraph Engineers (England) was organized at the beginning of the year 1872, and the first general meeting was held on the evening of February 28, 1872.

This society has been the most successful and far-reaching one of its kind, as its 16 well-filled annual volumes of proceedings testify. During the early part of its history the subjects brought before it for discussion were almost exclusively of a telegraphic character, for the very good reason that telegraphy was the only important application of electricity up to the year 1877.

The telephone and electric light produced a change in this respect, and some years ago the society added to its already long name the words "and Electricians." It is now considering again the subject of a change of name, and seems inclined to adopt some title which shall more fully indicate the character and scope of the work which by the force of circumstances it has been compelled to assume. The tone and merit of the papers read and of the discussions during the last three or four years, seem scarcely up to the high standard of the years when the society

was young; and a hasty judgment would ascribe this partly to the introduction of subjects connected with rival business interests, and partly to the circumstance that the new science of electricity with its dependent arts has grown so fast, and is still growing so fast that it is impossible to formulate definite opinions with any well grounded hope, that they will not within a year or two be upset by experience. The society is, however, an example to us on this side of the water, in that it does bring forward a large number of subjects for discussion, and that its programmes are as liberal in variety as they are in amplitude.

Some of our electrical societies in America seem to regard their function as being the establishment of an electrical arena wherein the respective advocates of direct incandescent lighting, and the converter (or as they call it in Great Barrington, Mass., the "*exhorter*") or alternating systems may fight it out. Of course all this tends to increase knowledge, and also to emphasize the self-evident fact that "there is much to be said upon both sides," as the monkey remarked while acting as umpire; nevertheless one gets tired of even canvas-back duck, if one gets it three times a day for a month, and it is to be hoped that our societies (they mostly call themselves "clubs") will not get into a rut, but will occasionally treat us to a new bill of fare.

• • •

BICYCLIST Thomas Stevens, who is not less entertaining as a writer than he is enthusiastic as a wheelman, tells in one of his letters his delight at seeing a telegraph line in Persia. Teheran, Ispahan and Shiras are the principal telegraph stations in the land of the Shah; but there are, of course, other offices, some of them being dreary and lonely indeed for the operators. Mr. Stevens is a genuine American, but he pays a deserved tribute to the solidity and thoroughness of British telegraph line construction. The observer confesses that our English cousins do surpass their American relatives in this respect. But then we must not forget that, although Julius Cæsar was not an electrical engineer, he did show the Britons how to make good roads, while the American Indian who formerly prowled around this land of ours, always tried to walk in the narrow way. The different ways of the former possessors of our respective countries may have something to do with the case.

SOME PROMINENT MEN IN ELECTRIC LIGHTING.

(See Frontispiece.)

GEORGE W. STOCKLY.

PRESIDENT, BRUSH ELECTRIC CO.

MR. GEORGE W. STOCKLY has been conspicuously identified with the development of electric lighting throughout its commercial history, as president and general manager of the Brush Electric Co. from its inception. A native of Cleveland, Ohio, which city has always been his home, Mr. Stockly will attain his forty-fifth year December 20 next. At the present time he has accomplished work and achieved results, both in reputation and fortune, which would well occupy and reward the efforts of a long life.

Mr. Stockly's school training did not extend beyond that afforded by the public grammar and high schools of his native city. He was strongly inclined to the profession of law, and on leaving school in 1861, he began legal studies in the office of Messrs Willey & Cary, a prominent law firm of Cleveland. At the end of two years the death of his father threw upon him such responsibilities for the care of the family, that he felt obliged to relinquish his cherished desire for a legal career, and to seek immediately remunerative employment. He began commercial life in the commission house of Messrs. Bond & Morris: subsequently, and until his first connection with electrical business in 1873, he held positions in the offices of the Cleveland and Pittsburgh Railroad, the Cleveland Omnibus Line, and in the Commercial National Bank of Cleveland. In the latter connection he served as receiving teller two years and as paying teller five years.

In March, 1873, Mr. Stockly, together with Mr. John E. Cary (of the law firm with whom he had studied twelve years earlier), bought a large interest in the business of the Cleveland Telegraph Supply and Manufacturing Co., which had been founded the previous year under the presidency of the late Geo. B. Hicks. Mr. Stockly left the bank and took charge of the business of the company as vice-president and manager. Mr. Hicks died a month later, and Mr. Stockly found himself thus charged with well-nigh the sole conduct of a difficult business, with which he had little acquaintance and no experience. The situation spurred him to the labor of mastering the business in all its details. How successfully he did this is shown by his remaining at the head of the management of the company, and its successors up to the present time. The company was soon reorganized under the name of the Telegraph Supply Company. Although less than fifteen years ago, the period was a day of small things in electrical business. The company's force of workmen numbered not more than twenty, and there were but few larger electrical shops in the country. The electric light was wanted for use and needed for business, and it came along, reaching the young company at the hands of Mr. Chas. F. Brush during the winter of 1876-'77. Mr. Brush's successful invention and production of dynamos and arc lamps became the foundation of the great manufacturing and commercial business since and now carried on under Mr. Stockly's management. In 1880 the name of the company was changed, very appropriately, to the Brush Electric Co. The little shop has grown to a number of buildings, covering several acres of land, and giving work to about seven hundred men. With able associates in the directory of the company, Mr. Stockly's admirable business qualifications have fully supplemented Mr. Brush's inventive talent and mechanical skill in achieving the remarkable commercial success of the company.

ENOS M. BARTON.

PRESIDENT, WESTERN ELECTRIC CO.

MR. ENOS M. BARTON was born in Jefferson County, New York, December 2, 1842, and descends, on the side of both father and mother, from an English ancestry by way of New England. When a lad of about twelve years he began work as a telegraph message boy at Watertown, N. Y., thus early entering the field which, in its subsequent expansion, was to become the scene of his life work, if that term can fairly be applied to the career of a man still four years under fifty. From this period he was dependent upon his own resources for his support and for his future. While in the Watertown office he learned to be a telegraph operator, by which vocation he afterwards maintained himself while pursuing college studies. In 1859 he went to Rochester, N. Y., entering the university of that city, where he completed one year's course and part of the next, supporting himself by night service in the telegraph office, where his duties consisted, for the most part—to use his own words—"in reporting himself awake every fifteen minutes." In 1862 he went to New York, where he worked as an operator, and at the same time completed his sophomore college year at the New York University.

In his twenty-second year Mr. Barton returned to Rochester, relinquishing a further college course, and henceforth devoting himself to work and business. He resumed work as an operator, and during his four or five years in Rochester made some not very successful ventures in Western Union stock. There was little if any encouragement for telegraphers at this period; salaries were gradually but steadily reduced, and in the autumn of 1868 Mr. Barton went into the business of electrical manufacturing with Mr. George Shawk, at Cleveland, Ohio. Subsequently, Mr. Elisha Gray bought Shawk's interest, and in 1870 the firm of Gray & Barton moved their business to Chicago, where it soon acquired importance, and became the nucleus upon which the business of the Western Electric Manufacturing Co. was founded in 1872. In the Cleveland days Mr. Barton was bookkeeper, shipping clerk, salesman, cashier and business manager, his partners looking after the workshop.

In the spring of 1872 the business of Gray & Barton was consolidated with that of the Western Union Telegraph Co.'s shop, at Ottawa, Ill., and both were merged in the Western Electric

Manufacturing Co., with a capital stock of $150,000. The late General Anson Stager was president of the new company, Mr. Barton was secretary, and Mr. Gray superintendent of the shop.

A factory was built on Kinzie street, Chicago, to which the Ottawa shop was removed, and in which the company continued its work for some years. The managers of the company took for their field of operations the whole range of electrical applications, and beginning with little else than telegraphic machinery and supplies, rapidly and steadily added new branches of work, until now its business includes nearly everything electric that can be named, from a push-button and box-bell to an electric light installation.

In April, 1879, The Western Electric Manufacturing Co. acquired the shops of the Western Union Telegraph Co. at New York, and increased its capital stock to $300,000.

In 1881 the Western Electric Co., with a capital stock of $1,000,000 was organized to succeed to the business of the Western Electric Manufacturing Co., and at the same time the business of Charles Williams, Jr., of Boston, Mass., and of the Gilliland Electric Manufacturing Co., of Indianapolis, was absorbed by the new company. About the same time the Bell Telephone Manufacturing Co., of Antwerp, was organized as a branch of the Western Electric Co., under the managership of Mr. F. R. Welles, and a little later an office and salesroom in London was opened by the Western Electric Co. During the present year the business of the Standard Electrical Works has been taken over by the Western Electric Co.

The business of the Chicago factory was moved in 1883 to the present extensive and well-appointed building in South Clinton street. The company is now erecting a large and commodious factory at the corner of Thames and Greenwich streets, New York city.

During the entire sixteen years of its history Mr. Barton, in the offices of secretary, vice-president and general manager, and president of the Western Electric Co. and its predecessor, has been its active executive officer. Together with General Stager, whose abiding faith in the policy of combination, and skill in carrying it out, were so striking a feature of his official relations with telegraph and other corporations, he planned and brought about the series of consolidations and acquisitions that have placed the present company in its commanding position in relation to nearly all branches of electrical work. Mr. Barton possesses, in an eminent degree, the stable qualities of foresight, firmness and patience. Like most strong men he has an abundant sense of humor, and not seldom answers a question, or conveys his views or instructions to his associates or subordinates, by telling a pointed story or making an apt quotation, which is sure to be amusing or edifying, and is usually both.

After the death of General Stager in 1885, Mr. Wm. S. Smoot was elected president of the Western Electric Co., and after his death, early in the following year, Mr. Barton was elected president.

H. M. BYLLESBY.

VICE-PRESIDENT AND GENERAL MANAGER, WESTINGHOUSE ELECTRIC CO.

MR. BYLLESBY'S career, and the prominent and responsible position already achieved by him, constitute a signal illustration of the relatively early age at which most of the men prominent in the development of the more recent applications of electricity to useful arts have accomplished important work and attained general reputation.

Mr. Byllesby is still less than thirty years old, having been born in 1859. He received his education at Lehigh University, Bethlehem, Pa. Mechanical engineering was the pursuit he set before himself, and soon after leaving college he entered the Corliss Engine Works, where he spent four years in congenial work and in acquiring a comprehensive practical acquaintance with the designing and construction of machinery.

To a well trained mechanical engineer the rapid growth of electro-mechanics, which followed the successful introduction of electric lighting as a commercial industry, could not fail to be an attractive field of activity, and in 1878 Mr. Byllesby entered it. He spent a year with Mr. Edward Weston, in association with whom it is needless to say he found opportunity to acquire an extensive knowledge, both theoretical and practical, of dynamic electricity and its related arts.

Mr. Byllesby next entered the service of the Edison Electric Light Company, and remained with them some five years, finding, in their widely and rapidly expanding business, opportunity and occasion to become further familiar with both the technical and commercial features of the industry.

After leaving the service of the Edison company, Mr. Byllesby for some time engaged in electric lighting business on his own account, making and executing contracts for installation.

Upon the formation of the Westinghouse Electric Company in 1885, Mr. Byllesby was engaged by that company to take a prominent part in the promotion of its venture into the electric field. He threw himself into the work with such energy and efficiency as to bring himself rapidly to the front, and within a year from his engagement was made general manager of the company. Three months after this appointment he was elected vice-president, which office he still holds, together with that of general manager.

Mr. Byllesby's clean-cut, energetic manner of transacting business, together with his extensive knowledge of the technical part of the electric lighting industry, and his inventive talent, have unquestionably contributed largely to the remarkable growth of the business of the Westinghouse company.

RONALD T. McDONALD.

TREASURER AND GENERAL MANAGER, FORT WAYNE JENNEY ELECTRIC LIGHT CO.

THE vigorous and aggressive qualities characteristic of the management of the Fort Wayne Jenney Electric Light Co. are easily discerned in the countenance of Mr. McDonald, its treasurer and general manager.

Mr. McDonald was one of the incorporators of that company in 1882, and became at once a director, assuming at the same time the conduct of its business as an executive officer.

Mr. McDonald has not yet reached his fortieth year. He is a native of Pennsylvania, and was born in Allegheny City in 1849. He entered the army as a drummer boy during the War of the Rebellion, and became a soldier before its close. He had no academic education, never having gone beyond the common schools of his home.

He began his business life in the dry goods trade, and at an early age became a member of the firm of Evans & McDonald, at Fort Wayne, Ind., wholesale dealers and jobbers in dry goods.

Mr. McDonald left the dry goods trade to take up the wholly unrelated business of electric lighting; took a prominent part in organizing the Fort Wayne Jenney company; became at once the manager of its business, and still continues as its leading spirit in the enterprising and successful operations of that company.

Quick perception and prompt action, alertness in observation and movement, characterize Mr. McDonald's administration of the business of his company. Competition is the proper field of action for such energetic and combative natures, and Mr. McDonald's success in building up a widely extended business in electric lighting, an industry which, at the time of starting the Fort Wayne Jenney company, had already become securely established, and was in the hands of a few strong companies, sufficiently attests his fitness for the initiation and maintenance of a competitive business, against well-established and fortified opposition.

The Fort Wayne Jenney, under his management, has become one of the leading arc light companies, and is rapidly gaining a foothold in incandescent lighting.

ARTICLES.

SHALLENBERGER'S ELECTRIC METER.

Some months ago, a new application of the alternating current in the production of rotary motion was made known almost simultaneously by two experimenters, Nikola Tesla and Galileo Ferraris, and the subject has attracted general attention from the fact that no commutator or connection of any kind with the armature was required. The principle has been very successfully applied by Mr. Tesla in the production of a practicable motor, which is destined soon to occupy an important place among the growing number of electrical appliances depending upon alternating currents for their operation.

For some time previous to the publication of the results above referred to, Mr. O. B. Shallenberger, electrician of the Westinghouse Electric Co. had been at work on a series of experiments tending in the same direction, the results of which served as a basis for the construction of a meter depending on analogous principles, something that could be made and used in a rough and ready way, without diminishing its reliability.

This, it is thought, has now been accomplished, although the use of the instrument in its present form is limited to alternating currents. In this connection it may be observed that although a few years ago one of the objections raised against the use of alternating currents was the difficulty in measuring them in a practical way, the fact is that these difficulties have gradually disappeared, until they are less important than in the use of direct currents.

The principle upon which the new meter operates may be understood from the following considerations. If an alternating current be made to traverse a coiled conductor in proximity to two other conductors closed upon themselves, the secondary currents set up in these two conductors will correspond with each other to a greater or less extent in phase, and will be approximately in the same direction at the same instant, but both will differ in phase from the primary or inducing current. An attraction consequently takes place between the two secondary circuits, and if free to move the conductors carrying these currents will be attracted to each other in a greater or less degree

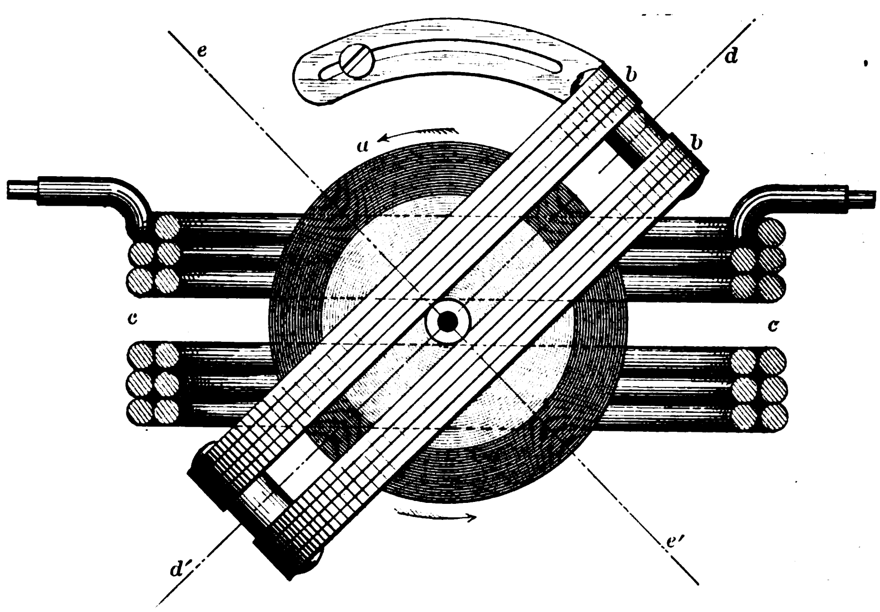

Figure 1.

although applied in a way differing notably from anything described up to the present time by either of the investigators referred to. The meter was already completed in an experimental form at the time when the results of the experiments of Mr. Tesla and Mr. Ferraris were made known, and its thorough practicability was demonstrated, although for legal reasons it was unadvisable to make the fact known at that date.

Notwithstanding the urgent need of a meter wherever electric lighting has been carried on commercially, nothing has presented itself thus far that indicated any decided advance in this direction, until the advent of the instrument invented by Professor Forbes, the great simplicity and beauty of which cannot be gainsaid. The one apparent difficulty in the way of its adoption seems to be its extreme delicacy and the necessarily minute accuracy in its manufacture and adjustment required to obtain satisfactory results.

It has been the desire of Mr. Shallenberger to produce a meter equally simple, but, if possible, more practicable in its nature, and requiring a less degree of skill on the part of the workmen in manufacturing; or in other words, depending on the amount of the primary current and on the displacement of phase between the primary and secondary currents. If one of these conductors be made fixed and the other movable, the motion will evidently be confined to one of the conductors, and if the action can be continued so as to produce the attraction always in the same direction, a continuous, rotary motion may be obtained by the inductive action solely, and without any direct communication with the source of current. The discovery of this principle suggested at once the practicability of applying it to the operation of a meter since it is only necessary to produce a rotary effort or torque in some simple and reliable way, bearing a definite relation to the current that produces it, in order to have a perfectly accurate means for measuring such current.

With this end in view a number of experiments were made which it is unnecessary to follow here, presenting a great variety of effects depending in a general way upon the principle referred to, and leading eventually to the form of meter here described.

It was found that one of the conductors might be replaced by a core of iron, inasmuch as the mutual

attraction between the iron core and the coil could be made to serve in place of the attraction between the two secondary coils, and with greater effect so long as proper relations were maintained to carry out the same mode of operation. If a disc of iron be surrounded by a copper band and this with another conductor at an inclination to the first, the passage of a current through the outer coil

b b are copper plates punched in the form of a flattened oval and riveted together at the ends, placed so as to surround the disc closely without touching it. These are adjustable in position with respect to the coil *c c*, which surrounds the whole. When in the position shown the rotation of the disc is in the direction of the arrows, and the torque is greatest when the plane of the coil shown by

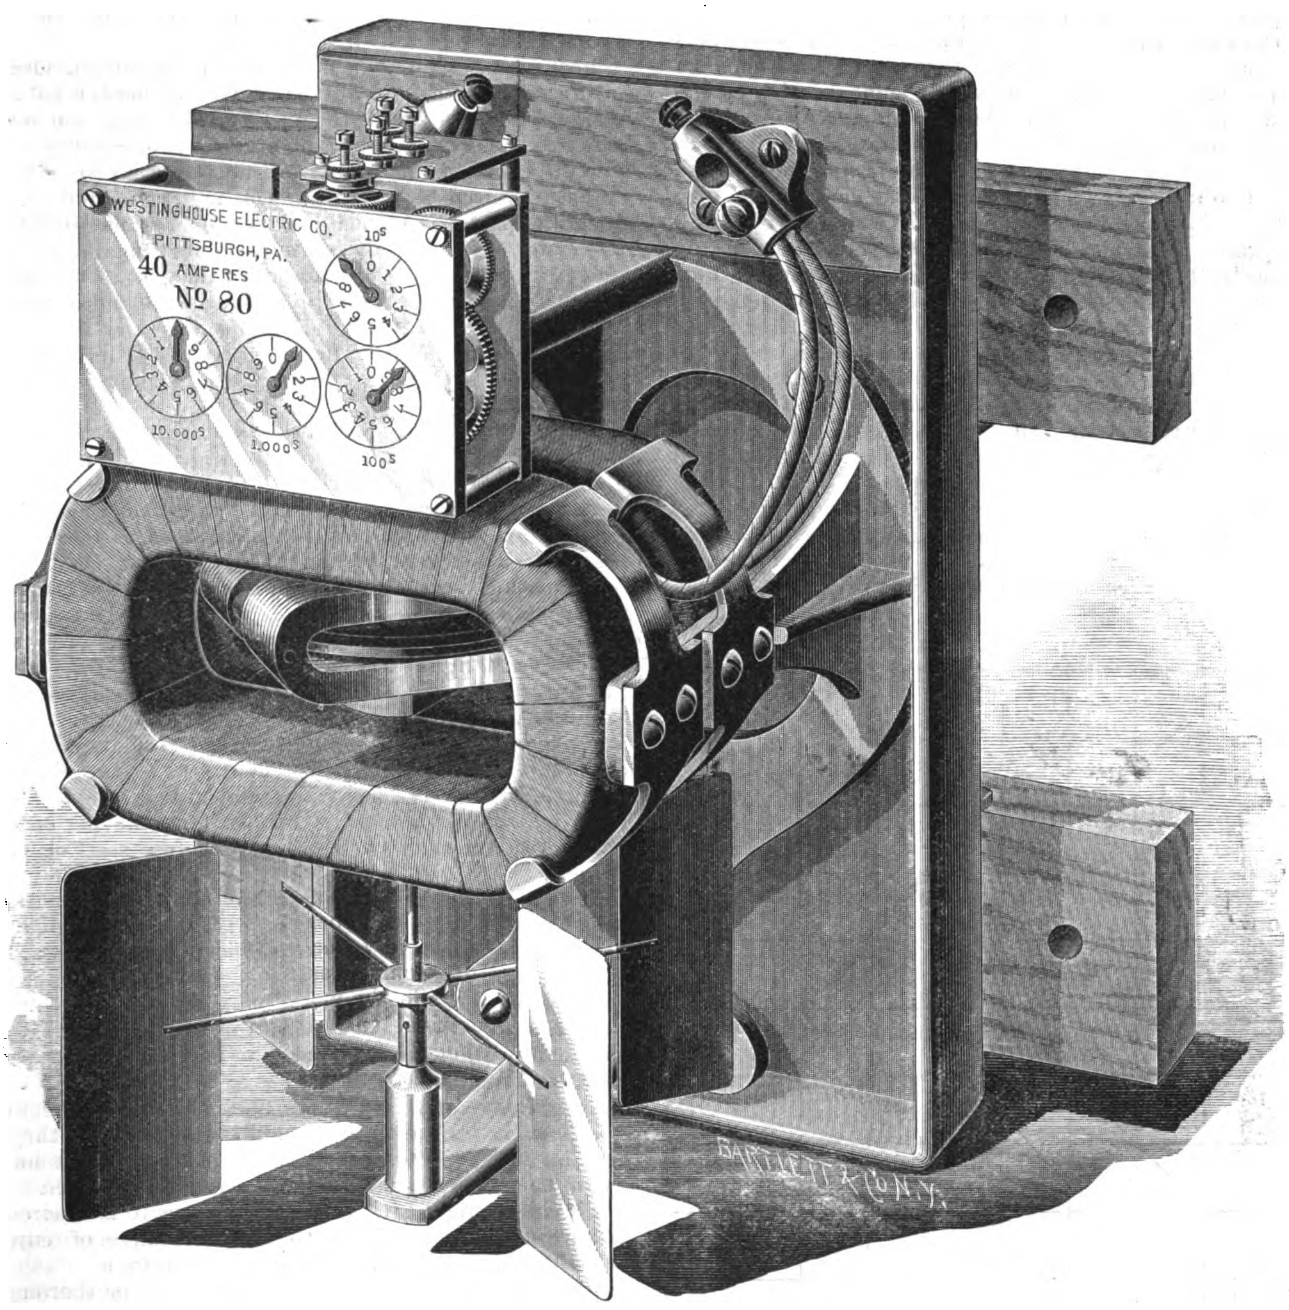

FIGURE 2.—Shallenberger's Meter (case removed).

will, by the action of the secondary currents set up in the short-circuited coil, produce a rotation of the disc; and the torque exerted is approximately proportional to the square of the current, so long as the rate of alternation is maintained approximately constant.

Referring to the diagram, figure 1, *a* is a flat ring of soft wrought iron mounted on a light disc of brass or aluminum, rigidly attached to a slender steel shaft.

the line *d d'* is at an angle of 45° to that of the coil *c c* If while the current is passing through the coil the position of the plates *b b* is changed gradually to *e e'*, the speed of rotation of the disc diminishes until an angle of 90° is reached, and beyond this the direction of rotation reverses, reaching maximum speed again at 45° on the opposite side.

In applying this to the meter only a few degrees move-

ment of the secondary conductors *b b* is required for the necessary adjustment.

This arrangement was selected from a large number of others because of its ease of construction, the small self-induction it introduces, and its ease of adjustment.

The maximum torque is exhibited at an angle between the coils of 45°, while at 0° and 90° it disappears altogether. When the angle is 0° the coils being parallel have a maximum mutual induction, but no torque is exerted; and at 90° no current is induced in the secondary coil, and consequently there can be no torque in that position.

In order that the speed of the disc may be proportional to the current it is necessary that some resistance be offered to its motion, which bears the same relation to the speed as that of the torque to the current, and the simplest means of doing this is to attach to the same shaft on which the disc is carried a suitable number of light vanes, whose motion is opposed by the resistance of the air as the disc revolves. This resistance is found to vary almost exactly in the proper ratio, and consequently the revolution of the disc is as nearly as possible proportional to the strength of the current. The rotations of the disc are counted by a train of wheels connected with an indicator similar to that used for gas meters, and showing ampere hours. The accuracy of the instrument is affected slightly by changes in the rate of alternation of the current; but since in practical electric lighting the rate of alternation is maintained nearly constant, the error due to this cause is quite insignificant, being less than proportional to the number of alternations. The adjustment to the exact speed required is made by changing the angle of the secondary coil; but in practice the instrument is made very nearly correct as it leaves the factory, requiring only slight correction.

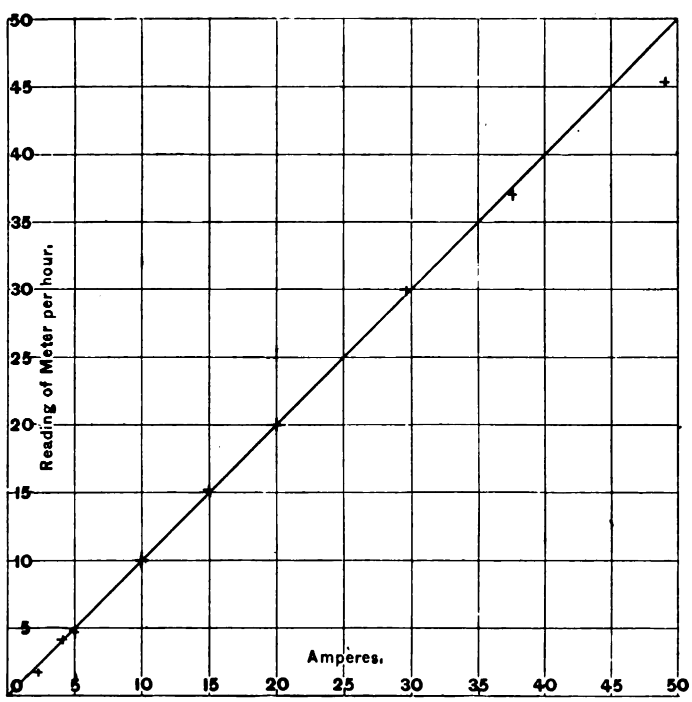

FIGURE 3.—Test of Shallenberger's Meter.

TEST OF 40 AMPERE METER.

Current in amperes.	Reading of meter.	Percentage of error.
2.06	1.6	
4.02	4.07	+1.2
5.00	4.95	—1.0
9.9	10.02	+1.2
15.0	15.1	+0.7
20.0	20.0	0.0
29.7	30.0	+1.0
37.4	37.0	—1.1
	Overloaded	
49.3	45.4	—7.9

The accompanying chart and table show the operation of a 40 ampere meter, with currents varying from the smallest capable of turning the vanes and overcoming the slight friction of the bearings, to an overload of 25 per cent. Currents are measured on the horizontal line, and the corresponding readings of the meter are shown by the vertical distances. It will be seen that the departure from the theoretical straight line representing the mean performance of the meter is very slight, and in no case within the working limits reaches two per cent., except at starting point; while at 25 per cent. overload, the proportional rate only falls off 7.9 per cent.

The ease with which this meter may be adapted to circuits of different capacity is obvious. By interposing between the meter and the circuit to be measured a small converter, the current may be reduced or increased in any ratio, and since the energy transformed by such converter is only the amount required in operating the meter, namely, about one-eighth of one per cent. of the energy measured, the dimensions of the converter may be very small, and consequently but very little is added to the cost of the simple meter. By changing the ratio of this converter any capacity may be given to the meter, so that the same instrument may be used to measure 10 lights or 10,000 lights within the same percentage of accuracy and without change in its construction.

There is, however, one feature worthy of notice in this connection, namely, the point at which the meter will begin to turn, or in other words, the percentage of its full load at which the registering of the current begins. This, in the 40 ampere meter already mentioned, is 1½ amperes, or say three per cent. of the rated capacity. While this represents only one or two lamps on a 40 ampere meter, and only one lamp on a 20 ampere meter, it will be seen at once that on a meter for 1,000 lamps the same proportion would give 30 lights required to start the counter.

In order to overcome this difficulty for the larger sizes of meters a shunt coil is provided, which, with a current almost inappreciable in amount, charges the inducing coil of the meter to a degree sufficient barely to overcome the inertia and friction of the vanes, and in this way the large meter may be made to start on less than one per cent. of its full load as easily as the small meters start on three per cent.

There are certain cases in which it is very desirable, even where a large number of lights are installed, to measure a comparatively small proportion of the total current. Lamps are sometimes used for watch lights and other purposes, while the main body of the lamps are or are not in operation, and it is for this reason that the shunt coil is applied. Its operation may be made as sensitive as the conditions require.

The greater simplicity of the meter having a direct coil only, both in its construction and connection in the circuits, makes it preferable not to employ the shunt coil on any of the smaller sizes, namely, below 40 amperes. But it is evident that in special cases where it is desired to measure accurately the widest possible range of current the shunt coil can be employed with advantage.

Practical tests have shown this meter to be thoroughly reliable in its action, and with the exception of some minor details in the construction, no serious difficulties have presented themselves at any time. The meter as now manufactured for practical use seems to fill the requirements very satisfactorily, and has given no cause to doubt its entire reliability within limits of error much smaller than have hitherto been obtained in ammeters, voltmeters, and similar instruments.

. . . Now let it be proposed to put underground all the tens of thousands of wires in the city (New York), telegraph, telephone and electric light, in close proximity as they must be, in many cases, and I think the problem would appear appalling to any one except a commissioner or newspaper reporter who knew nothing about it.—*Professor Wm. A. Anthony*

DISCUSSION OF THE PRECISION OF MEASUREMENTS.[1]

BY SILAS W. HOLMAN, S. B.

Associate Professor of Physics, Massachusetts Institute of Technology.

(Concluded from page 300.)

$m_3 = r, \delta r = 0.001 r = 00.2$ cm. Direct measurement of the diameter $2r$ by a steel scale, correct within 0.1 mm., may be made at many diameters. This is liable to errors from irregular thickness of insulation (causing uncertainty as to position of wire), from irregular winding, and from ellipticity of coils. An AD for r as small as 0.02 cm. may be obtained on a good coil by careful work. It is usually better to measure the outer circumference of the coil by a steel tape, and the average thickness of the coil, and thence to compute r; or, better still, to measure the circumference of each layer as it is wound. A circumference measurement to $AD = 0.01$ cm. would give $\delta r = \frac{0.01}{6.3}$ cm., since circumference $= 2\pi r$. Sometimes the length of the wire to compose the coil is measured before winding, and r computed from this length and n. But liability to stretch renders this result unreliable except with heavy wire wound and measured with great care.

$m_4 = n$. This is necessarily a whole number, and unless $n = 1000$ or more, cannot be in error by one turn without producing a greater effect than

$$\frac{\delta C}{C} = 0.001.$$

$m_5 = \tan\varphi \therefore \delta m_5 = \delta \tan\varphi = 0.001 \tan\varphi$. Since $\tan\varphi$ is a variable, we must study its δ as a fraction of φ. $\frac{d(\tan\varphi)}{d\varphi} = \sec^2\varphi \therefore \frac{\delta\tan\varphi}{\tan\varphi} = \frac{2\,\delta\varphi}{\sin 2\varphi}$. Several important points deducible from this expression will be given later. $\frac{\delta\tan\varphi}{\tan\varphi}$ is a minimum for $\varphi = 45°$, as will be seen by inspection. This value only will be considered here. For this, $\frac{\delta\tan\varphi}{\tan\varphi} = \frac{\delta C}{C} = 0.001$, $\delta\varphi = 0.001$, $\frac{\sin 2\times 45°}{2} = 0.0005$. The arc whose length is radius is 57°.3 appr. $\therefore \delta\varphi° = 0.0005 \times 57. = 0°.03$ about. The galvanometer considered is read to 0°.1 by eye estimation of tenths of degree. It is assumed that in a single estimation the maximum error will be $\frac{1}{10}$ degree. A value of φ is the mean of four readings. The case falls under the first special law of deviations. Therefore, the $a\ d$ of single estimation $= \frac{0.05}{2} = 0.025$, and for the mean of the four readings, $\delta' = \frac{0.025}{\sqrt{4}} = 0°.013$. Thus the errors of stimation in reading $\varphi =$ less than $\frac{1}{2}$ the δ prescribed. But there are also errors in φ from eccentricity (eliminated by averaging), irregular graduation, inclination of mirror and graduated circle to horizontal, inclination of plane of coils from vertical, and displacement of plane of coils from magnetic meridian. Irregularity of graduation must be separately studied and corrected, though the averaging of four readings reduces its effect. The other sources of error mentioned will be discussed later, and it will be shown that with care they can be rendered negligible in effect. The combined errors of estimation and graduation may easily fall within $\delta\varphi = °0.03$.

In discussing the correction terms we may desire to know: 1st, Values of δ's to make the correction term either of a given effect, $\frac{\delta C}{C}$, or negligible so that it may be omitted. 2d, Values of the magnitude of the quantities entering into the correction which will make its effect either of a given amount, or zero, or negligible.

The correction terms are all factors of the form $m = (1 + A)$ when A is a function of one or more quantities, x, y, etc., and is small, relatively, to unity. Hence,

$$\frac{dm}{dx} = \frac{d(1+A)}{dx} = \frac{dA}{dx} \therefore \delta m = \delta A,$$

and as $m = 1$ (sensibly),

$$\frac{\delta m}{m} = \frac{\delta A}{1} = \delta A.$$

Thus, for $\frac{\delta m}{m} = 0.001$, $\delta A = 0.001$, and for $\frac{\delta m}{m} < 0.0001$; *i. e.*, negligible, $\delta A < 0.0001$.

$m_6 = \left(1 + \frac{1}{2}\cdot\frac{b^2}{r^2} - \frac{1}{3}\cdot\frac{d^2}{r^2}\right)$ is the correct factor for dimensions of coil-section, when $2b$ and $2d$ do not exceed 0.1, or, better, 0.05 of r. Consider first values of δ's which, with the given magnitudes of $2b$ and $2d$, will make $\frac{\delta m_6}{m_6}$ negligible; *i. e.*, less than $\frac{1}{10} \times 0.001$. We must then have $\delta A = \delta\left(\frac{1}{2}\cdot\frac{b^2}{r^2} - \frac{1}{3}\cdot\frac{d^2}{r^2}\right) < 0.001$. As r must be determined more closely for use in m_3 than for this correction, δr may be here disregarded. Applying XXII. for equal effects of δ's, we have

$$\Delta = 0.0001,\ n = 2, \therefore \frac{\Delta}{\sqrt{n}} = 0.0007.$$

$\frac{dA}{db} = \frac{b}{r^2}$, $\frac{dA}{dd} = -\frac{2}{3}\cdot\frac{d}{r^2}$, or as $2b$ and $2d$ are the measured quantities,

$$\frac{dA}{d2b} = \frac{b}{2r^2},\ \frac{dA}{d2d} = -\frac{1}{3}\cdot\frac{d}{r^2}, \therefore \delta 2b = \frac{\Delta}{\sqrt{n}} \Big/ \frac{dA}{d2b}$$
$$= 0.06 \text{ cm.},\ \delta 2d = 0.07 \text{ cm.}$$

Of course we might similarly compute the values of $\delta 2b$ and $\delta 2d$ for $\frac{\delta C}{C} = 0.001$, but this is unnecessary, as it is obvious that the narrower limit just computed can be attained, and thus the correction rendered sensibly exact.

For magnitudes of b and d. The correction will be negligible when $A < 0.0001$. Inspection shows that A is zero when $\frac{1}{2}\cdot\frac{b^2}{r^2} = \frac{1}{3}\cdot\frac{d^2}{r^2}$; *i. e.*, $\frac{b^2}{d^2} = \frac{2}{3}$, or $\frac{b}{d} = \frac{4}{5}$ approx.

For the given galvanometer it is only necessary then to have these proportions exact within $\delta 2b = 0.06$ cm., and $\delta 2d = 0.07$ cm., in order to have the correction vanish. It is obvious that this proportion of $b : d$ may be considerably departed from without loss of accuracy, if only the correction be carefully determined and applied. It should, however, be borne in mind that the form of the correction assumes a uniform distribution of wires in the coil-section.

$m_7 = \left(1 - \frac{3}{4}\cdot\frac{l^2}{r^2} + \frac{15}{4}\cdot\frac{l^2}{r^2}\sin^2\varphi\right)$ is the correction factor for length of needle when $2l$ does not exceed 0.1 to 0.05 of r. As in m_6 we may consider r as exact. A similar statement applies to φ. We have, therefore, to deal only with

1. Copyrighted, 1888, by S. W. Holman.—From *Technology Quarterly*.

$\delta\, 2\, l$. Consider first values of $\delta\, 2\, l$, which, with the given magnitude of $2\, l$, will render

$\frac{\delta m_7}{m_7}$ negligible ; *i. e.*, < 0.0001. As A contains φ, which, though exact, is not constant, it should be studied for all values of φ. But for its best work the galvanometer will be used only between $\varphi = 30°$ and $60°$, and it will be shown that A increases from $\varphi = 26°.6$ upward. Hence it will suffice to compute for the worst case. Substituting then

$\varphi = 60°$, we find $A = 2\,\frac{l^2}{r^2}$ nearly.

$$\therefore \frac{d\,A}{d\,l} = \frac{4\,l}{r^2}, \therefore \delta\, l = \frac{r^2}{4\,l}.\ \delta\, A, \therefore \delta\, 2\, l = \frac{r^2}{2\, l}\,\delta\, A = 0.04 \text{ cm.},$$

which is easily attainable. Note that $2\, l$ is the distance between the magnetic poles of the needle, which is about 0.85 of the whole length if the needle is a straight, thin prism.

The correction will vanish when $\frac{3}{4}.\ \frac{l^2}{r^2} = \frac{15}{4}.\ \frac{l^2}{r^2}.\ \sin^2\ \varphi$.

Solving this for φ gives $\varphi = 26°.6$. Hence the correction vanishes whatever the length $2\, l$ (within limit $0.1r$), when the deflection is $26°.6$. For the given galvanometer the correction cannot be disregarded nor rendered negligible between $30°$ and $60°$, because 1 cm. is about as small as $2\, l$ can be made without introducing too great torsion correction, and $\delta\, 2\, l$ cannot be reduced much below 0.04 cm.

$m_8 = \left(1 + \frac{\varphi\,\Theta}{\sin\ \varphi}\right)$ is the correction factor for torsion when this is not unduly great. This does not take account of initial torsion, which is in part eliminated by reading reverse deflections. In this factor φ may be regarded as exact, for reasons similar to those given for r and φ in m_7 and m_6. But though exact, φ varies. Inspection shows that as φ increases more rapidly than its sine, the value of m_8 increases up to $\varphi = 90°$. Hence, for reasons similar to those given under m_7 in a similar case, we may consider only $\varphi = 60°$. Substituting this value gives $A = 70.\ \Theta$ nearly. To find value of $\delta\ \Theta$ to make $\frac{\delta\, m_8}{m_8}$ negligible, *i. e.*, $\delta\, A < 0.0001$, we have

$$\frac{d\,A}{d\,\Theta} = 70, \therefore \delta\ \Theta = \frac{0.0001}{70} = 0.00\,000\,14.$$

To ascertain whether this is attainable in the given instrument, we must know how closely Θ may be found in it. With the needle strongly magnetized and suspended by a single fine fibre, Θ may be as small as 0.00 005, or even 0.00 001, and may be determined within ten per cent. of its value ; *i. e.*, with $\delta\ \Theta = 0.00\,000\,5$ to $0.00\,000\,1$. Hence, torsion factor in such case may be determined with such closeness that $\frac{\delta\, m_8}{m_8}$ is negligible, but the correction must be applied in this grade of work.

$m_9 = \left(1 + \frac{3}{2}\,\frac{x^2 + y^2 - 2z^2}{r^2}\right)$ is the correction factor which serves to correct for the displacement of the centre of the needle from the centre of the galvanometer coil, x and y being the rectangular components of this displacement in the plane of the coils, and z the component perpendicular to that plane, x, y and z being small in proportion to r. By inspection, therefore, it appears that along any surface whose equation is $x^2 + y^2 - 2\, z^2 = 0$ the correction would disappear. If a limiting value, a, be assigned to x, y and z, each, the correction will be a maximum when $z = 0$ and $x = y = a$, or when $x = y = 0$, and $z = a$. As all values between 0 and a will occur, the correction term may have any value from 1 to $1 \pm 3\,\frac{a^2}{r^2}$. The law of distribution of the errors will be a special one, but will not differ widely from the general one. Hence the $a\, d$ may be assumed as about $\frac{3}{4}.\ \frac{a^2}{r^2}$. See paragraph on Estimated Precision Measures, p. 198]. In order, then, that m_9 be negligible, we may write

$$\frac{3}{4}.\ \frac{a^2}{r^2} < \frac{1}{10} \times 0.001 = 0.0001 \therefore a^2 < 0.0001\,\frac{4 \times 400}{3} = 0.05$$

cm. $\therefore a < 0.22$ cm. That is, the centre of the needle should be within a radius (on the average) of less than about $\frac{1}{4}$ cm., which is easily possible.

m_{10} is the correction factor for the inclination of the circle to the horizontal, which would, of course, introduce error into φ. The graduated circle is assumed to be rigidly attached to the mirror. Suppose the circle and mirror inclined by an angle h to the horizontal. The line of sight is always normal to the mirror. Imagine a right circular cylinder erected with the graduated circle as a base. Then the accompanying figures will represent projections of this cylinder. E''', F''', will be the projection of the circle upon a vertical plane. $G\ I$ will be another projection of the circle upon a plane at right angles to the former and parallel to the axis of the cylinder,—which, of course, is the direction of sight in reading. $E'\ A'\ F'\ I'$ is the projection of the circle on a plane parallel to itself, and, therefore, shows the circle in its true dimensions, as it is always seen, because the lines of projection are here the lines of sight. The *horizontal* plane swept through by the index would be then that indicated by $A\ B\ E\ K—A''\ D''\ E''$, making an angle h with the plane of the circle. This plane will intersect the cylinder in an ellipse $A\ B\ E\ K—A''\ D''\ E''—A'\ B'\ E'\ I'\ F'$.

1°. Let A, A', A'' be the zero point of the circle and index. Let the needle be deflected to the position D'', B, B'. The real angle of deflection φ of the needle in the horizontal plane will be represented in the diagram only by its projections, $A\ C\ B—A'\ C'\ B'$. The observed angle is $\varphi = A'\ C'\ B'$, which is, of course, the projection of φ upon the base of the cylinder. We must find some equation connecting φ and φ'. Pass a plane tangent to the cylinder along the element $A\ G—A'$. Its trace in the plane of the circle will be $M'\ A'\ D'$. Prolong $C'\ B'$ until it intersects $M'\ A'$ at D', and locate on the other projections the corresponding points D'', D'''. Then $\tan\,\varphi' = \frac{A''\ D''}{r}$ when $r = A\ C = A'\ C' = E'\ C' =$ radius of circle. Also, $\tan\,\varphi = \frac{A'D'}{r} = \frac{A'''\ D'''}{r}$. Hence $\frac{\tan\,\varphi'}{\tan\,\varphi} = \frac{A'''\ D'''}{A''\ D''} = \cos\ h \therefore$ $\tan\,\varphi = \frac{\tan\,\varphi'}{\cos\,h}$, and we may write $C = \frac{10\,H}{G}\,\frac{\tan\,\varphi'}{\cos\,h}$.

The effect of inclining the mirror *in this case* is thus the same as inclining the coils in the cosine galvanometer.

2°. If the angles be measured from E, E', E'' as zero position, then $\tan\,\varphi = \tan\,J\ C\ E$ revolved $= \frac{J\,E}{A''\,E''}$; $\tan\,\varphi' = \tan J'\ C'\ E' = \frac{J'\,E'}{r} = \frac{J\,E}{r} \therefore \frac{\tan\,\varphi'}{\tan\,\varphi} = \frac{A''\ E'}{r}$ $= \frac{A''\ E''}{E''\ L} = \frac{1}{\cos\,h} \therefore \tan\,\varphi = \tan\,\varphi'\,\cos\,h.$

3°. If the zero line be neither $A\ C$ nor $E\ C$ then the correction will be unsymmetrical, but, as it will not in any case differ widely from the above values, it is unnecessary to discuss the general expression.

It may be seen by inspection that the reading of both ends, and of reversed currents, will not affect this error. In the demonstration it has also been assumed that the projections of the centre of the needle was upon the centre of the circle. If this is not the case a variable eccentricity will be introduced, which will be eliminated by the ordinary method of reading both ends of the needle.

In order that the error from h may be negligible, we must have $\frac{\tan\varphi - \tan\varphi'}{\tan\varphi} \overset{=}{<} 0.0001$. From equation in 1° case $\frac{\tan\varphi - \tan\varphi'}{\tan\varphi} = \frac{1-\cos h}{1}$, and in 2° case $= \frac{\cos h - 1}{\cos h}$, which, for small values of h, $= \frac{\cos h - 1}{1}$ appr. Thus for small values of h the difference in the two cases is merely one of sign. To be negligible we have, then, $\cos h = 1 - 0.0001 = 0.9999$; whence $h < 0°.8$, which would require care in original adjustment of plane of mirror to horizontal, and corresponding care in subsequent leveling of galvanometer.

m_{11} is the correction term for ellipticity, or irregularity of coils. The strength of field at the needle due to unit current in the coils might be found by integration. This will increase in intensity as the coil becomes more elliptical. But the value of the integral will change slowly with small eccentricity of the ellipse; and as it is easy to keep the difference between the major and minor axes within limits of a fraction of a millimeter, it seems that the error may be considered as then negligible—though always tending to produce a + error in C as computed on the supposition of a circular coil. Irregular winding of the coils tends to produce a similar effect.

m_{12} is the correction factor for plane of coils not being vertical. Let v be the angle by which the plane is inclined to the vertical. The effective part of the field G is then its horizontal component only, viz., $G \cos v$. This error will, therefore, be negligible, similarly to m_{10} when $1 - \cos v < 0.0001$, or $v < 0°.8$ about.

m_{13} is the correction factor for plane of coils being out of magnetic meridian. If it is so, the field F at the centre, due to the current, is oblique to H and $\varphi_1 >$ or $< \varphi_2$, *i. e.*, the deflections on opposite sides of the zero are unequal. In figure 1 the plane of the coils is inclined by w to the west of north, *i. e.*, by a — angle. The deflection usually employed is $\frac{1}{2}(\varphi_1 + \varphi_2)$, these being *the angles swept through by the pointer* in passing from its normal position when the *needle* is in the meridian to that when the needle is successively in the directions of the resultant fields with reversed currents. Of course corrections may be made for error of index from zero of scale when at normal position, but no advantage is thus gained. The error m^{13} may be eliminated by turning the coils by trial until, when corrected for initial position of pointer, $\varphi_1 = \varphi_2$; but exact adjustment is

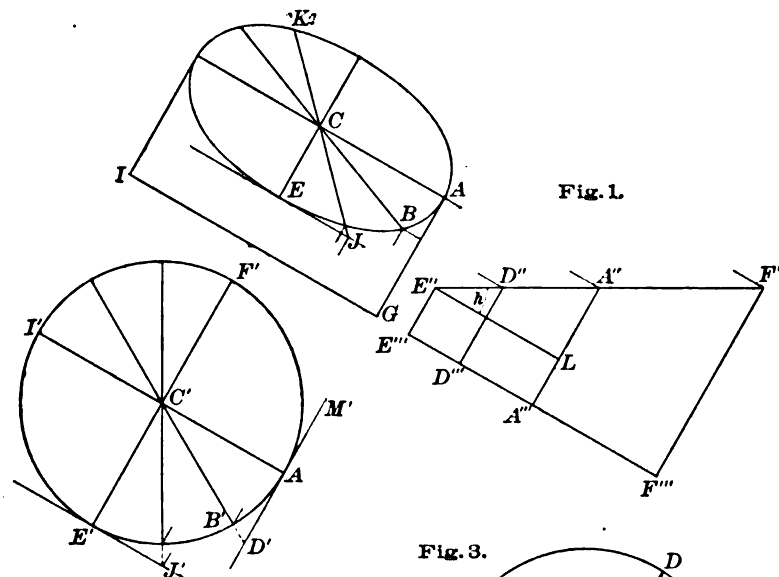

Fig. 1.

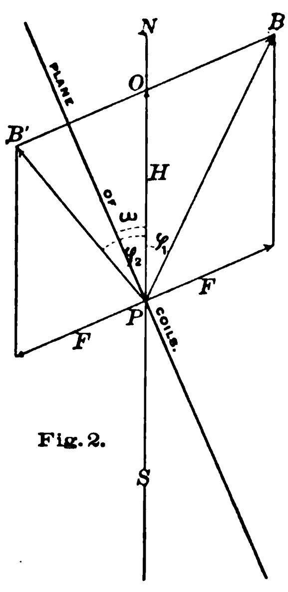

Fig. 2.

Fig. 3.

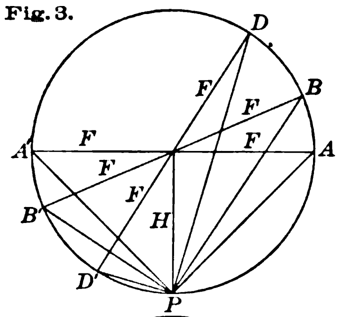

Fig. 4.

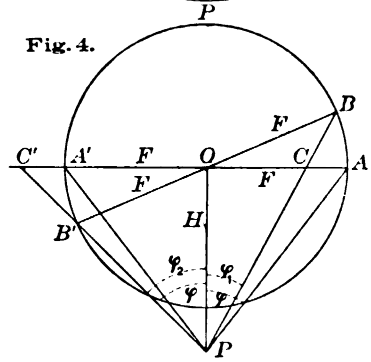

troublesome, and it is, therefore, necessary to know the best process, and how small it is necessary to make w in order that it may be negligible.

In the figures, F is the field due to the current in the coils; w = angle between plane of coils and meridian; φ = the true angle of deflection; φ_1 and φ_2 = the observed deflections with reversed currents. Figures 2 and 4 show the constructions to find, by triangle of forces, the direction and magnitude of the resultant fields PA, PA', PB, PB', etc, and thus the values of φ, φ_1 and φ_2. Figure 3 is the solution for the case when $F = H$, *i. e.*, where $\varphi = 45°$, where it appears that whatever the value of w [$= AOB$, or AOD, etc.] the value of $\varphi_1 + \varphi_2$ [$= BPB'$ or DPD', etc.] is always 90°, so that $\frac{1}{2}(\varphi_1 + \varphi_2)$ will be φ, the true deflection. This surprising result points very strongly to the use of deflections of about 45° when *accurate* values of C are sought. Figure 4 represents the general case, and from it the following demonstration gives the general expression connecting φ, $(\varphi_1 + \varphi_2)$, and w.

$$\text{In } OBP, \frac{OC}{OB} = \frac{\sin OBC}{\sin OCB} = \frac{\sin(90° + w + \varphi_1)}{\sin(90° + \varphi_1)}$$

$$= \frac{\cos(w + \varphi_1)}{\cos\varphi_1} = \frac{OC}{F}$$

$$\therefore \tan\varphi_1 = \frac{OC}{H} = \frac{F}{H}\cdot\frac{\cos(w+\varphi_1)}{\cos\varphi_1} = \tan\varphi\cdot\frac{\cos(w+\varphi_1)}{\cos\varphi_1}$$

$$= \tan\varphi\,[\cos w - \sin w\,.\,\tan\varphi_1] = \tan\varphi\cos w - \tan\varphi\,.\,\sin w\,.\,\tan\varphi_1$$

$$\tan\varphi_1 = \frac{\tan\varphi\,.\,\cos w}{1 + \tan\varphi\,.\,\sin w}.$$

$$\text{In } OB'P\ \frac{OC'}{OB} = \frac{\sin OB'C'}{\sin OB'B'} = \frac{\sin(90° - w + \varphi_2)}{\sin(90° - \varphi_2)}$$

$$= \frac{\cos(\varphi_2 - w)}{\cos\varphi_2} = \frac{OC'}{F}.$$

$$\therefore \tan\varphi_2 = \frac{OC'}{H} = \frac{F}{H}\cdot\frac{\cos(\varphi_2 - w)}{\cos\varphi_2} = \tan\varphi\cdot\frac{\cos(\varphi_2 - w)}{\cos\varphi_2}$$

$$= \tan\varphi\,[\cos w + \sin w\,.\,\tan\varphi_2] = \tan\varphi\cos w + \tan\varphi\,.\,\sin w\,.\,\tan\varphi_2.$$

$$\tan\varphi_2 = \frac{\tan\varphi\cos w}{1 - \tan\varphi\,.\,\sin w}$$

$$\tan(\varphi_1 + \varphi_2) = \frac{\tan\varphi_1 + \tan\varphi_2}{1 - \tan\varphi_1\,.\,\tan\varphi_2} = \frac{\dfrac{\tan\varphi\,.\,\cos w}{1 + \tan\varphi\,.\,\sin w} + \dfrac{\tan\varphi\cos w}{1 - \tan\varphi\sin w}}{1 - \dfrac{\tan^2\varphi\sin^2 w}{1 - \tan^2\varphi\sin^2 w}}$$

$$= \frac{2\tan\varphi\cos w}{1 - \tan^2\varphi} = \frac{2\tan\frac{1}{2}(\varphi_1 + \varphi_2)}{1 - \tan^2\frac{1}{2}(\varphi_1 + \varphi_2)};$$

$\therefore (1 - \tan^2\frac{1}{2}(\varphi_1 + \varphi_2))\tan\varphi\,.\,\cos w = (1 - \tan^2\varphi)\tan\frac{1}{2}(\varphi_1 + \varphi_2)$; $\therefore \tan\varphi\,.\,\cos w\,.\,\tan^2\frac{1}{2}(\varphi_1 + \varphi_2) + (1 - \tan^2\varphi)\tan\frac{1}{2}(\varphi_1 + \varphi_2) = \tan\varphi\cos w$; $\therefore \tan\frac{1}{2}(\varphi_1 + \varphi_2) =$

$$\frac{\tan^2\varphi - 1 \pm \sqrt{\{\tan^4\varphi - 2\tan^2\varphi + 1 + 4\tan^2\varphi\cos^2 w\}}}{2\tan\varphi\,.\,\cos w.}$$

The upper sign of the $\pm$ must be taken for the radical. For suppose $w = 0$, then $\sqrt{\{\text{etc.}\}} = \tan^2\varphi + 1$ and $\tan\frac{1}{2}(\varphi_1 + \varphi_2) = \frac{\tan^2\varphi - 1 \pm (\tan^2\varphi + 1)}{2\tan\varphi}$, which with the upper sign is $\tan\frac{1}{2}(\varphi_1 + \varphi_2) = \frac{2\tan^2\varphi}{\tan\varphi} = \tan\varphi$, which is, of course, the proper value, while that obtained by taking the lower sign would not be so. Hence

$$\tan\tfrac{1}{2}(\varphi_1 + \varphi_2) = \frac{\tan\frac{1}{2}(\varphi - 1 + \sqrt{\{\tan^4\varphi + 2\tan^2\varphi\,.\,\cos 2w + 1\}}}{2\tan\varphi\,.\,\cos w.}$$

For the case already solved geometrically, when $\varphi = 45°$.

$$\tan\tfrac{1}{2}(\varphi_1 + \varphi_2) = \frac{1 - 1 + \sqrt{(1 - 2 + 1 + 4\cos^2 w)}}{2\cos w} = \frac{2\cos w}{2\cos w} = 1.$$

For $\varphi = 90°$ (impossible on tangent galvanometer) $\tan\frac{1}{2}(\varphi_1 + \varphi_2) = \frac{\infty}{\infty}$ which is indeterminate in form.

The simplest way to study the effect of this error is to plot a series of values of $\frac{\delta C}{C}$, for various values of φ, obtained by computing $\tan\frac{1}{2}(\varphi_1 + \varphi_2)$ by the above equation for a series of small values of w. From such a plot made with values of $\frac{\delta C}{C}$ as ordinates, and of w as abscissas, we may find that the value allowable, in order that $\frac{\delta C}{C}$, shall not exceed the negligible amount 0.0001 is about $w = 0°.5$, when the values of φ are between 30° and 60°. This closeness cannot be attained without careful adjustment of the plane of the coils by some such method as that to be described. For a limit $\frac{\delta C}{C}$, $= 0.001$ the value of $w = 2°.5$, about, is sufficiently close,—a closeness easily reached without special attention in a well-made instrument.

Method of adjusting tangent galvanometer to meridian.—Set the graduated circle with line of zero points as nearly as practicable in plane of coils. See that index is very nearly parallel to axis of needle. Turn plane of coil until index is parallel to line of zeros. Then coil is approximately in meridian. Pass constant current to produce about 45° $= \varphi_1$ (defl. of N. end to E), read both ends and take mean $= \varphi_1$. Reverse current and find φ_2. Then $w = \varphi_2 - \varphi_1$. If w is +, the plane of coils is to W. of N.; w is always toward largest deflection. Turn plane in proper direction by w. This will be nearly right, but should be repeated, correcting now for initial position of needle, which is, of course, no longer zero. The proof is as follows:

From page 315, $\tan\varphi_1 - \tan\varphi_2 = \tan\varphi.\ \cos w \left(\frac{1}{1 + \tan\varphi\sin w} - \frac{1}{1 - \tan\varphi\sin w}\right)$; and as $\sin w$ is quite small, $\tan\varphi\sin w$ is negligible in denominators, and $\tan\varphi_1 - \tan\varphi_2 = \tan\varphi.\ \cos w\ (-2\tan\varphi.\ \sin w)$ approx. $= -2\tan^2\varphi.\ \sin w\cos w = -\tan^2\varphi.\ \sin 2w\ \therefore \sin 2w = \frac{\tan\varphi_2 - \tan\varphi_1}{\tan^2\varphi}$. Write $\varphi_2 - \varphi_1 = \Delta$, a *small* angle, and substitute $\varphi_1 = 45° = \varphi$ approx. Then $\sin 2w = \frac{\tan(\varphi_1 + \Delta) - 1}{1}$. Now $\tan(\varphi_1 + \Delta) = \frac{\tan\varphi_1 + \tan\Delta}{1 - \tan\varphi_1\tan\Delta} = \frac{1 + \tan\Delta}{1 - \tan\Delta} = 1 + 2\tan\Delta$ approx. $\therefore \sin 2w - 1 + 2\tan\Delta - 1 = 2\tan\Delta$, and as w and Δ are both small,

$w = \Delta = \varphi_2 - \varphi_1$. For angles other than 45° the general expression for $\sin 2\, w = \frac{\tan \varphi_2 - \tan \varphi}{\tan^2 \varphi}$ must be employed.

RESULTS.

Tangent galvanometer used between 30° and 60°.

	Factor.	Val. of δ for $\frac{\delta C}{C} = \frac{\delta m}{m} =$ 0.001	Values attainable by correction and adjustment. δ	$\frac{\delta C}{C}$
m_1	$\frac{10}{2\pi}$	0.00 16	[$\pi = 3.1416$]	negligible.
m_2	H	0.00 017	0.00 030	0.0018
m_3	r	0.02 cm.	0.02 cm.	0.001
m_4	n	. . . .	0	0
m_5	$\tan \Phi$	$\delta \Phi = 0°.08$	$\delta \Phi = 0°.03$	0.001
m_6	Dimensions of coil sec.	. . . .	$\delta 2b = \delta\, 2d = 0.06$ cm.	0.0001 negl.
m_7	Length of needle.	$2l = 0.9$ cm.	$\delta l = 0.04$ cm.	0.0001 negl.
m_8	Torsion	$\theta = 0.00\,001\,4$	$\delta\theta = 0.00\,000\,14$	0.0001 negl.
m_9	Needle out of centre	$a = 0.7$ .cm	$a = 0.22$ cm.	0.0001 negl.

m_{13}	Coils out of meridian	$w = 2°.5$	$w = 0°.5$	0.0001 negl.

Inspection shows that the chief source of error is in H. If each m be allowed to affect C by $\frac{\delta C}{C} = 0.001$, the resulting effect will be $\frac{\Delta C}{C} = 0.001 \sqrt{13} = 0.0036$, or about 0.4 per cent. If the corrections and adjustments be made as indicated in columns 4 and 5, we shall have $\left(\frac{\Delta C}{C}\right)^2 = 0.0018^2 + 0.001^2 + 0.001^2 + 7 \times 0.0001^2$ (negl.) $= 0.0023^2$, or $\frac{\Delta C}{C} =$ about 0.25 per cent. Relative current measurements do not involve H, and $\therefore$ for them $\Delta = 0.0014$, or about 0.15 per cent.

Tangent galvanometer. Best range of deflections.—To determine what this range is, we have to consider the effect on $\frac{\Delta C}{C}$ of 1°, a change $\delta \varphi$ in the reading; 2°, the length of the needle; 3°, the torsion of the suspension; 4°, deviation of plane of coils from the magnetic meridian in the original adjustment. It will be shown that if 2° and 3° be corrected, the best working deflection, *i. e.*, the value of φ, which will make $\frac{\Delta C}{C}$ a minimum, is $\varphi = 45°$, but that any deflection from 30 to 60° is not sensibly worse than 45°, and that the range of 20° to 70° is almost as good; giving a range of currents of 3 : 1 in the first case, and 7.5 : 1 in the second. The kind of tangent galvanometer referred to is, of course, the same as elsewhere considered in these notes.

1°. *Change of $\delta \varphi$ in the deflection reading.*—$C = R \tan \varphi \therefore \frac{\delta C}{C} = \frac{2\, \delta \varphi}{\sin 2\, \varphi}$, as before. On any given instrument where φ is read by a circle, an average value of $\delta \varphi$ will be found, which is independent of φ; $\therefore \delta \varphi =$ constant. Hence $\frac{\delta C}{C}$ will be a minimum when $\sin 2\, \varphi$ is a maximum, *i. e.*, when $\varphi = 45°$. Moreover the value of $\frac{\delta C}{C}$ will be symmetrical about the point $\varphi = 45°$, because the value of $\sin 2\, \varphi$ will be so.

$\varphi =$	$\frac{\delta C}{C} = \frac{2\delta\varphi}{\sin 2\varphi} =$
0° or 90°	$\pm\ \infty$
5 or 85	± 0.00589
10 or 80	.00292
15 or 75	.00200
20 or 70	.00156
25 or 65	.00131
30 or 60	.00116
35 or 55	.00107
40 or 50	.00102
45 or 45	.00100

The preceding table gives values of $\frac{\delta C}{C} = \frac{2\, \delta \varphi}{\sin 2\, \varphi}$ for $\delta \varphi = \pm 0°.03$, which would give $\frac{\delta C}{C} = 0.001$ at $\varphi = 45°$ The table might equally well be computed from a table of tangents, since $\frac{\delta C}{C} = \frac{\delta \tan \varphi}{\tan \varphi}$, $\delta \tan \varphi$ being the change for $\delta \varphi = \pm 0°.03$. A curve plotted with values of φ as abscissas and of $\frac{\delta C}{C}$ as ordinates, or inspection of the table, will show that up to $\varphi = 30°$ or 60° the value of $\frac{\delta C}{C}$ changes by but ⅙th its value at 45°, and is therefore sensibly uniform, and even up to $\varphi = 20°$ or 70° it increases by but ½ its value at 45°. Hence as far as $\delta \varphi$ in reading is concerned, the tangent galvanometer of this form is equally precise from 30° to 60°, and almost as much so from 20° to 70°.

2°. *Length of needle.*—The correction for this has been already shown to be zero at $\varphi = 26°.6$. If the correction is made properly or is small enough to be negligible, the resident error will be a minimum at 26°.6, so that as far as this affects the result (*i. e.*, very slightly), the *best* working angle would be slightly under 45°.

3°. *The torsion correction* increases with φ, and hence whether it is corrected or not this would indicate an advantage in small rather than large deflections.

4°. *The deviation of the coils* from the meridian has been shown to be of no effect at $\varphi = 45°$; and as it is difficult, mainly on account of initial torsion, to obtain certainty in this adjustment, there appears here a decided reason for considering $\varphi = 45°$ the best working angle.

On the whole, then, 45° seems the best angle; but when torsion and length of needle are corrected, the range of 30° to 60° is about as good, and even 20° to 70° not decidedly worse; but beyond 20° and 70° the galvanometer should not be employed except in coarse work.

Electro-static capacity. Thomson's and Gott's methods.—[Method described in Kempe's H'b'k of El. Test'g, Ed. 1887, pp. 335, 339.] Formula is $F_x = \frac{R}{R_x} . F$. The battery power used is assumed to be sufficient to enable a

change of the smallest coil in the resistance box to be perceived, so that the precision condition is $\delta R = \delta R_x$. The charges in the condensers, and therefore the sensitiveness of the apparatus, is greatest when the total resistance $R + R_x$ is as large as possible, viz., the total in the box. Hence the magnitude condition is $R + R_x = r$, a constant, or $R_x = r - R$.

By formula XVI. for factors

$$\left(\frac{\Delta F_x}{F_x}\right)^2 = \left(\frac{\delta R}{R}\right)^2 + \left(\frac{\delta R_x}{R_x}\right)^2 = \frac{1}{R^2} + \frac{1}{R_x^2}\,\delta^2 R.$$

Now $\frac{\Delta F_x}{F_x}$ must be a minimum, which will occur when

$\frac{1}{R^2} + \frac{1}{R^2_x}$ is so. By XXX.

$$-\frac{2}{R^3} - \frac{2}{R^3_x}\cdot\frac{d}{dR}\,(r - R) = 0 \therefore \frac{2}{R^3} = \frac{2}{R^3_x}$$

and $R : R_x = 1$ will be the best ratio. But this will hold when $F = F_x$. The best magnitude of F is then F_x; *i. e.*, the known condenser should be equal to the unknown, or that condition should be approached as nearly as may be.

This problem is also capable of a simple solution which may serve to indicate methods for other similar ones. Substituting $R_x = r - R$ gives

$$F_x = \frac{R}{R_x}\cdot F = \frac{R}{r - R}\cdot F.$$

By definition $\frac{\delta F_x}{\delta R} = \frac{d F_x}{d R} \therefore \delta F_x = \frac{d F_x}{d R}\cdot \delta R.$

$$\therefore \delta F_x = \frac{r F}{(r - R)^2}\cdot \delta R \therefore \frac{\delta F_x}{F_x} = \frac{r F}{(r - R)^2}\cdot\frac{r - R}{R F}\cdot$$

$$\delta R = \frac{r}{r - R}\cdot\frac{\delta R}{R}.$$

We have now, for a given value of $\frac{\delta R}{R}$, to find the value of R which will render this a minimum, r being a constant.

$$\therefore \frac{d}{dR}\left(\frac{1}{R(r - R)}\right) = 0 = \frac{-r + 2R}{R(r - R)}, \therefore R = \frac{r}{2}, \text{ or}$$

$R_x = R$, and $F = F_x$.

Magnetometer. In measuring $M \div H$ by the magnetometer, the deflecting magnet is placed successively at two distances, r_1 and r_2 from the needle, producing deflections φ_1 and φ_2. And

$$\frac{M}{H} = \tfrac{1}{2}\cdot\frac{r_1^5 \tan\varphi_1 - r_2^5 \tan\varphi_2}{r_1^2 - r_2^2}.$$

Desired, the best ratio of $r_1 : r_2$; *i. e.*, that which will make $\Delta \frac{M}{H}$ a minimum. The measurements are such that δr_1 and δr_2 may be considered negligible, and $\delta \tan \varphi_1 = \delta \tan \varphi_2$; thus these are the precision conditions. There are no magnitude conditions which bear on this problem. Then

$$\frac{d}{d(\tan\varphi_1)}\left(\frac{M}{H}\right) = \frac{r_1^5}{r_1^2 - r_2^2}, \text{ and } \frac{d}{d(\tan\varphi_2)}\left(\frac{M}{H}\right) =$$

$$\frac{-r_2^5}{r_1^2 - r_2^2}\cdot \therefore \Delta^2\frac{M}{H} = \frac{r_1^{10} + r_2^{10}}{(r_1^2 - r_2^2)^2}\cdot\delta^2(\tan\varphi).$$

To make $\Delta\frac{M}{H}$ a minimum, the fraction in the second member must be a minimum; and we wish, therefore, to find the value of $r_1 : r_2$, which will make it so. Writing, then, $r_1 : r_2 = n$, or $r_1 = nr^2$, and substituting gives

$$\frac{r_1^{10} + r_2^{10}}{(r_1^2 - r_2^2)^2} = \frac{nr_2^{10} + r_2^{10}}{(nr_2^2 - r_2^2)^2} = r_2^6\cdot\frac{n^{10} + 1}{(n^2 - 1)^2},$$

in which we have to find the value of n to produce a minimum. Where the two variables are independent, as in this case r_1 and r_2 are independent, the following proposition may be often of service.

Let $u = f(x, y)$ where x and y are independent variables and f is such a function that it may be separated, so that

$$u = \rho(x).\ \sigma\left(\frac{x}{y}\right).$$

Then the value of $x : y$, which makes $\sigma\left(\frac{x}{y}\right)$ a minimum, is the same as will make u a minimum. For x cannot be expressed as a function of $\left(\frac{x}{y}\right)$, and, therefore, $\rho(x)$ does not enter into the determination of $x : y$ for the minimum. The same is, of course, true if the separation be made into

$$u = \rho'(y).\ \sigma'\left(\frac{x}{y}\right)$$

Then in the problem in hand we have to find the value of n, which will make $\frac{n^{10} + 1}{(n^2 - 1)^2}$ a minimum.

$$\frac{d}{dn}\frac{n^{10} + 1}{(n^2 - 1)^2} = 3n^{10} - 5n^8 - 2 = 0. \therefore n = 1.32 \text{ approx.}$$

Electro-static capacity. Divided charge method.—This problem presents an additional point often arising.

F = capacity of known condenser.
F_x = capacity of unknown condenser.
Q = full charge of known condenser.
q = divided charge of known condenser.
q_x = charge put into unknown condenser, but not measured. Then $q_x : q = F_x : F, \therefore q_x + q : q = Q : q = F_x + F : F, \therefore F_x = F\left(\frac{Q}{q} - 1\right)$. Required the ratio $Q : q$ for greatest precision. Since charges are measured by reflecting galvanometer $\delta Q = \delta q$. By nature of the measurement F is a wholly independent quantity, so that Q is independent of F_x, but q is conditioned by F_x and Q. But in the observations, of course, δQ and δq are independent of these conditions. Hence

$$\Delta^2 F_x = \left(\frac{d F_x}{d Q}\cdot\delta Q\right)^2 + \left(\frac{d F_x}{d q}\cdot\delta q\right)^2 = \left[\left(\frac{F}{q}\right)^2 + \left(-\frac{F Q}{q^2}\right)^2\right]\delta^2 q.$$

Substituting value of F_x and transposing gives

$$\left(\frac{\Delta F_x}{F_x}\right)^2 = \left[\left(\frac{Q}{(Q - q)q}\right)^2 + \left(\frac{1}{Q - q}\right)^2\right]\delta^2 q.$$

Before proceeding to find minimum, we must obtain an expression not containing q in the right-hand member, since q is a function of F_x and Q. Write $q = \frac{Q}{n}$ where n is the desired ratio $Q : q$, and substitute. Then

$$\frac{\Delta F_x}{F_x} = \frac{n^4 + n^2}{(n - 1)^2 Q^2}\cdot\delta^2 q.$$

For a minimum the value of n must make the fraction

in the second member a minimum, and, therefore, by the proposition given in the magnetometer problem, as before.

$$\frac{d}{dn}\frac{n^4+n^2}{(n-1)^2}=0.$$

The solution of this gives $n^3-2n^2-1=0$, $n=2.2$ approx.

Battery resistance. In measuring battery resistance B by two deflections, assuming resistance box to be so exact that its errors may be neglected :—

1°. With any galvanometer for which $\delta\ C=$ constant, *e.g.*, a reflecting galvanometer. Call ρ_1 and ρ_2 the total resistances in circuit, inclusive of battery, when C_1 and C_2 are flowing. Then

$$\Delta^2 B=\left[\left(\frac{-\rho_1^2\rho_2}{E(\rho_2-\rho_1)}\right)^2+\left(\frac{\rho_1\rho_2}{E(\rho_2-\rho_1)}\right)^2\right]\delta^2\ C.$$

For best results we must make $C_1=2.2\ C_2$, *i. e.*, $\rho_2=2.2\ \rho_1$, and $\frac{\rho_1}{B}$ as small as possible consistently with avoidance of polarization effects. If $C_1=2\ C_2$ about, then $\frac{\Delta B}{B}=\sqrt{20}\ \frac{\rho_1}{B}\cdot\frac{\delta\ C}{C}$. To obtain $\frac{\Delta B}{B}$ with assigned closeness, we must use galvanometer of such sensitiveness that $\frac{\delta\ C}{C}<\frac{1}{\sqrt{20}}\cdot\frac{B}{\rho_1}\cdot\frac{\Delta B}{B}$.

2°. With any galvanometer for which $\frac{\delta\ C}{C}=$ constant, *e. g.*, a tangent galvanometer, $\Delta B=\sqrt{2}\ \frac{\rho_2\rho_1}{\rho_2-\rho_1}\cdot\frac{\delta\ C}{C}$. For best results C_1 should be as large and C_2 as small as is consistent with polarization and requisite sensitiveness. In a tangent galvanometer, using deflections of 60° and 30° for C_1 and C_2, respectively, the ratios will be about $C_1=3\ C_2$, *i. e.*, $\rho_2=3\ \rho_1$. Then $\frac{\Delta B}{B}=\frac{3}{\sqrt{2}}\cdot\frac{\rho 1}{B}\cdot\frac{\delta\ C}{C}=\frac{2\rho_1}{B}\cdot\frac{\delta\ C}{C}$ approx. Hence for best results with assigned value of $\frac{\Delta B}{B}$ we must make $\frac{\rho_1}{B}$ as small as is consistent with polarization and sensitiveness, and must use galvanometer of such sensitiveness that $\frac{\delta\ C}{C}<\frac{B}{2\rho_1}\ \frac{\Delta B}{B}$, and that with this value of $\frac{\rho_1}{B}$ the deflection will be about 60°. We must make ρ_2 such that the second deflection $=$ about 30°. If deflections of 70° and 20° are used with a galvanometer having the same value of $\frac{\delta\ C}{C}$ at these points as the former at 60° and 30°, the value of $\frac{\delta B}{B}$ will be about 0.8 as great. Still better results may be reached by the use of a potential galvanometer, together with a current galvanometer or external circuit of known resistance.

Battery e. m. f. By two deflections.

1°. For galvanometer where $\delta\ C=$ constant. $\Delta^2 E=\frac{\rho_2^4+\rho_1^4}{(\rho_2-\rho_1)^2}\cdot\delta^2\ C$, and inserting $x=\frac{\rho_2}{\rho_1}$ and $E=C_1\ \rho_1$, $\frac{\Delta^2 E}{E^2}=\frac{1+x^4}{(x-1)^2}\cdot\frac{\delta^2\ C}{C^2}$, which will be a minimum when $x=\frac{\rho_2}{\rho_1}=2.$ approx. The best ratio of the currents is, then $C_1=2.1\ C_2$, or sensibly the same as for the measurement of B. The value of $\frac{\Delta E}{E}$ is independent of the actual value of the resistance, as it involves only their ratio $\rho_2:\rho_1$.

2°. For galvanometer where $\frac{\delta C}{C}=$ const. $\frac{\Delta^2 E}{E^2}=\frac{\rho_2^2+\rho_1^2}{(\rho_2-\rho_1)^2}\cdot\frac{\delta^2\ C}{C^2}$ which has no minimum, but which diminishes as ρ_2 increases, or as ρ_1 diminishes, as may be best seen by inspection after writing the fraction in the form $\frac{\rho_2^2+\rho_1^2}{\rho_2^2+\rho_1^2-2\rho_2\rho_1}$. Hence we must make ρ_1 as small and ρ_2 as large as is practicable with due regard to polarization and sensitiveness.

Rogers' Laboratory of Physics, March 1888.

PRACTICAL NOTES CONCERNING THE CONSTRUCTION, USE AND MANAGEMENT OF STORAGE BATTERIES.[1]

BY A. RECKENZAUN.

(Continued from page 390, vol. vi.)

EXPERIMENTS WITH STORAGE BATTERY CARS.

During the month of December, 1887, a series of tests were instituted with electrical tramcars driven by accumulators and electric motors. Some of the tests were made with car No. 3 in the large yard of the Electric Car Company of America, in Philadelphia, and others with a second car sometimes on this experimental line and sometimes in the streets of the city named. These cars varied in dimensions, and they were differently constructed, therefore we attach numbers to each in order to distinguish them hereafter. The yard in which the rails were laid is an irregularly shaped four-sided space, and there are four curves, two of which have a radius of 50 feet, one 33 feet, and one 100 feet, measured to the centre of the track. The rails formed a complete circuit of 1,005 feet in length, and this we call one round trip. The rails tangential to the 33 feet curve were laid upon an ascending incline of 1 in 20, sloping down again beyond the summit of the hill at the rate of 6 feet in 100, and this slope finished with the 100 feet radius curve.

Car No. 3 contained 116 cells, all of which were used during this experiment in supplying current to two of the author's electro motors, which were fixed to a pair of bogies. The entire weight propelled was 7.4 tons; the battery alone weighed 2.14 tons, the rest being made up by the car itself, the motors and gearing, and the passengers on board.

Three men, each well trained for his work, were required for these tests, and their duties were as follows:—One man took charge of the switch in front of the car and the brake; in fact, he did the ordinary duties of a driver, taking care that the car ran at regulation speed on the level, that it did not "race down grades" nor go too slow up the inclines, and that it took the sharpest curves with safety. The second man with a timepiece in his hand counted the number of round trips and recorded it carefully, he also watched the voltmeter periodically. The third attendant had the most difficult task of taking readings on the ammeter and writing them down as fast as his skilled hand and pencil would allow it. It will be noticed that on a line of this description with constantly recurring curves and no straight piece of track of more than 200 feet in length, the energy consumed must vary continually. A sensitive ammeter, as near dead-beat as it can be made, was used, and the attendant could take and write down 41 readings during a round trip lasting on an average 1.45 minutes. This gave one reading to every two seconds about, and in order to do this with approximate accuracy some practice was required. Very few stoppages were made because it was the intention to ascertain the number of miles this car could make with one charge of accumulators on this awkward track, without allowing the

1. From the *Telegraphic Journal and Electrical Review* (London).

E. M. F. to drop below a certain minimum, and this minimum was fixed at 10 per cent. drop. The E. M. F. was taken every half hour; at the commencement the entire battery gave 227.36 volts when the car ran on a comparatively level part of the track, and this corresponds to 1.975 volts per cell. At the end of the experiment, the battery gave 205.42 volts under similar conditions, consequently there was a loss of nearly 22 volts between the first and the last readings. When near the summit of the hill the greatest amount of current, averaging 80 amperes, was used, and at that instant the E. M. F. dropped by about 14 volts below that used on the level, but it recovered immediately when the circuit was entirely broken on the down grade, or when reduced to its normal value on the level road.

The temperature of the air varied between 30° and 36° F., the rails were dry and tolerably clean, and we made 331 round trips, each of 1,005 feet, in exactly eight hours. This represented a total distance of 63 miles, or an average of nearly eight miles an hour. From the plan of the line we computed that the car had to traverse 5.438 miles of curved track of 33 feet radius; 10.4 miles of 50 feet radius, and 4.918 miles of 100 feet radius. The aggregate of ascending grades came to 5.656 miles, and the down grades to 5.128 miles, whilst the entire distance of straight and level track gave 22.46 miles.

About 13,000 observations were recorded on paper, these were averaged and gave a mean current rate of 18.5 amperes; down the grade and for a good distance beyond, the car was run by gravity; on leaving the 33 foot curve and entering the up grade the current gradually rose from 40 to 80 amperes, and on the level it varied between 10 and 15 amperes. By "level," we mean *comparatively* level, because the ground had undulations which represented slight gradients, but these were averaged up so as to give the value of a straight track.

The energy was thus consumed at an average rate of $216 \times 18.5 = 3{,}996$ watts; this gives 5.35 h. p., and for the entire 63 miles, 42.8 h. p. hours.

The maximum energy supplied at any moment by the battery was $213 \times 80 = 17{,}040$ watts $= 22.84$ h. p. Each car mile costs in this case .663 of a horse-power hour, which can easily be expressed in money value when we know the price of a horse-power hour in the prime mover. From the above it will be seen that the useful storage capacity of the accumulators was 148 ampere hours. Before the experiment commenced, the specific gravity of the acid in each cell was ascertained, and the average calculated, this gave 1,186 degrees. Immediately after the 63 miles, or 8 hours' run, the acid was again tested and gave an average of 1,130 degrees for the whole set; consequently, there was a fall of 56 degrees, which would give 1.3 degrees per horse-power hour, or nearly .89 degrees per car mile run.

The work done may also be expressed in ton miles, $7.4 \times 63 = 466.2$ ton miles, which caused an expenditure of 42.8 h. p. hours, or 10.88 ton miles per horse-power hour.

After the above experiment the accumulators were recharged until the acid density rose to 1,190 and gas bubbles came off freely. The average energy consumed during the charge was 6,181 watts for 7.5 consecutive hours, giving a total of 62.14 electrical horse-power hours. The cells were not new, but they have served the purposes of electric traction for six months preceding the present record.

As we are treating of the properties and uses of accumulators in particular, there is no need to give detailed descriptions of the construction of the motors, gearing, and other mechanical parts of cars, The efficiency and durability of the battery, however, is materially influenced by the efficiency of the devices used for propelling the vehicle, consequently a few remarks on constructive details will prove of service hereafter. Car No. 3, mentioned in the preceding article, was mounted on two bogies whose wheel-bases were comparatively short, 3 feet 8 inches; this gave great freedom of motion round the curves. The gauge of the track in Philadelphia is 5 feet 2¼ inches. and the rails are of the usual type used in that city, called the "flat rail." The power was transmitted between the motors and axles by means of worm gearing attached to one axle of each bogie. Variations of current to suit the requirements of tractive resistance were effected by varying the resistances in the motors. Each field magnet core was wound with two distinct coils, which by means of a suitable switch could be thrown in parallel or in series, and the motors, as a whole, could be worked in parallel, in series or singly. Thus a number of changes could be made without resorting to artificial resistances, and without excessive currents flowing at the start. Car No. 3 was specially built for electric traction; its length is 22 feet inside, 28 feet 2 inches over platforms, and 7 feet 6 inches wide over all. Car No. 1 is different in many respects. One motor only is used (Sprague type), which is geared to the aft axle by means of a pinion and spur wheel. The wheel base is 6 feet, there are only two axles, one of which is driven, and the car is of the ordinary two-horse type, 16 feet long in the body and 21 feet over the platforms. The accumulators were of the same type as those in car No. 3, but only 84 in number, arranged under the seats. The weight of this vehicle during the tests, with several men on board, was 5.3 tons. The conditions of the line and the atmosphere were similar to those in the former experiments. With this set of fully charged accumulators we made 231 round trips in 6½ hours, representing a distance of 43 8 miles. On an average, 22.6 amperes of current were used; the maximum on the grade of 5 per cent. rise was 70 amperes, on the level 20 to 25 amperes. Round the curves, owing to the greater wheel-base, this car ran slower than car No. 3 with the same amount of current, and the mean speed was just 7 miles per hour. The specific gravity of the cells averaged 1.184 degrees before the car started on its journey, and it dropped to 1.123 at the end, giving a difference of 61 degrees for 43.8 miles, or 1.415 degrees per car mile. Calculating the mean E. M. F. at 157 volts from actual measurements, we get an average of 4.75 h. p., giving a consumption of 29.69 h. p. hours supplied by the battery, whilst the maximum energy given off at any moment was $70 \times 150 = 10{,}500$ watts $= 14$ electrical horse-power.

Converting the work into ton miles, which is no doubt the most rational mode of comparing figures, we get $5.3 \times 43.8 = 232.14$ ton miles at an expenditure of 29.69 h. p. hours, and this gives nearly 7.78 ton miles per horse-power hour.

The energy expended per car mile was .678 h. p. hours; it will be seen that this was very little less in the case of car No. 3, yet there is a difference of 28 per cent. in favor of this car when we compare the relative consumption per ton mile. The re-charging of car No. 1 took 6 hours, at an average rate of 5,410 watts, and this amounted to 43.5 h. p. hours, with a fair overcharge. We find that in the case of tramcar propulsion, where the batteries are worked at a comparatively high rate, the efficiency of the accumulator never reaches above 70 per cent., measuring the energy at the terminals of the battery, both when charging and discharging, although the efficiency in ampere hours often exceeds 80 per cent; but this latter mode of expressing efficiencies is of little practical value.

EFFECT OF CONDITION OF ROAD UPON STORAGE BATTERY.

It will be seen that there is a great difference in the rate of current consumed according to the state the rails are in at different times. As a matter of fact the streets of Philadelphia are about the dirtiest of any city in the States, and there is sometimes so much dust that one can hardly see the top of the rails in places where much cross traffic occurs, through market carts and all sorts of wagons. After a good shower of rain the tram rails assume a tolerable clean appearance; there being no grooves except at curves, the mud is easily squeezed out by the flanges of the

car wheels; thus it happens that during or after a rainfall the energy necessary for propelling the vehicle is very much smaller than in dry weather. Although car No. 1 has made hundreds of trips through the city, *via* Spruce and Pine streets and Walnut and Chestnut streets, prior to the time when this record was made, we have only on very few occasions taken readings systematically. On one of these occasions we carried only about a dozen passengers; the weather was damp and therefore favorable. Readings were taken on the ammeter only, at the same rapid rate as formerly on the experimental track, and we worked out the averages between each "square," the streets of that city, as is well known, being divided into squares; at each square is a cross street, so that the rails of all the lines running at right angles to a certain route intersect, on an average, every 200 yards.

As our car ran faster than the horse car in front of us, we had to stop as often as they did when taking up and putting down passengers, or letting other traffic pass at the numerous crossings. Thus, on one round trip between Graysferry and the Exchange and back again, we used only 21 amperes of current on an average, each single trip taking about 40 minutes, the distance being 3½ miles. The maximum current at the grades and curves or both combined, amounted to 64.3 amperes. In order to show how irregularly the energy is consumed even on lines with moderate grades, we give here a few figures as examples. Taking the 10 squares in Pine street, going "up-town," the average currents for each square were 45.31 amperes between Fourth street and Fifth street, 40.31 between Fifth and Sixth, 16.05 between Sixth and Seventh, then 43.5, 21.05, 14.04, 30.58, 0, 16.53, and 27.7 between Thirteenth and Broad streets. On the return journey "downtown" through Spruce street, which is parallel to and next to Pine street, the currents were 9.16 amperes between Broad and Thirteenth streets, 0 between Thirteenth and Twelfth, then 13.84, 24.28, 28.0, 18, 9.4, 24.04, 20, and 17.15 between Fifth and Fourth streets respectively.

On another occasion, with the rails clogged with dry dirt, and 23 passengers on the car when going "downtown" and 40 passengers when returning, the currents between the same streets were as follows, viz.:—going from the Fourth street towards Broad street 48.66, 41.76, 20.55, 67.69, 43.43, 10, 36.25, 20.27, 22.85 and 33.33 amperes respectively. Returning again from Broad street to Fourth street, we had 31.25, 21.05, 42.64, 8.26, 26.59, 0, 16.53, 41.66, 0, and 20.62 amperes respectively. During the entire trip the average current rate was 36 amperes.

No. 3 car hauling No 1.—Tests were made to ascertain the current consumed by car No. 3 when propelling itself as well as car No. 1 attached to it, the apparatus of the latter being kept inactive during the experiment. Instead of running the vehicles round continuously, a start was made for each trip of 1,005 feet on our experimental line. Thus the current used on one trip of 1.5 minutes' duration was 41.1 amperes. The total weight propelled was 12.3 tons; the currents on the 5 per cent grade and on the 33 feet curve were necessarily very high, and the E. M. F. varied considerably owing to the great strain put upon the accumulator of the locomotive car; thus the E. M. F. on open circuit before starting gave 234 volts, at the instant of starting 220.5 volts, when going round the 33 feet curve 216 volts, and on the level 225 volts, and immediately after the car stopped it rose again to 230 on open circuit.

EXPERIMENTS WITH STORAGE BATTERY CARS.

Car No. 3, with a constant load of 7.4 tons, was next subjected to different tests by varying the number of cells actually in use; the cells were simply cut out of circuit, but they were kept on board so as not to diminish the weight carried. The track in the yard was in good condition, and the car was stopped and started at the end of each round trip of 1,005 feet. Four points of the switch were used, and for each point or position, which represented a distinct combination in the motor circuits, the speed of the car was ascertained. Thus, with 100 cells in use, and with the switch handle at the first notch when the motor circuit gave the highest resistance, since all the coils were placed in series, it took 2 minutes and 30 seconds to go once round from the instant of starting to a dead stop with the brake on; this gave an average speed at the rate of 4.56 miles an hour. With the switch handle at the second point the trip was made in 1 minute 50 seconds, equal to a rate of 6.218 miles an hour. At the third combination 1 minute 15 seconds, giving 9.12 miles; and with the fourth combination 1 minute and 5 seconds, showing a rate of 10.52 miles per hour, including time taken in starting and stopping.

With 90 cells in use the time taken on each round trip was as follows: first point on switch 2 minutes 53 seconds; second point, 1 minute 53 seconds; third point, 1 minute 20 seconds, and with the fourth combination 1 minute 10 seconds.

Then 80 cells were coupled up in series; with the switch handle at the first notch the car went all right until it nearly reached the summit of the hill where the grade is 5.5 per cent. for a short distance, and then it came to a standstill; the power with all the motor coils in series and the reduced E. M. F. was not sufficient to bring the load over this grade. The second combination gave ample power and the trip was made in 2 minutes 4 seconds; the third point 1 minute 35 seconds, and the fourth 1 minute 20 seconds.

With only 60 cells in use, and the load of 7.4 tons, we started on the third notch, which carried the car over the track easily in 1 minute 57 seconds; and the fourth notch, representing a powerful combination, completed the journey in 1 minute 20 seconds.

These tests were valuable in so far as they gave the exact speed for each position of the switch handle, and especially the results with different numbers of storage batteries. For ordinary speeds, and grades of the description given on page 7, we found that 100 cells showed the most economical results with all the variations of speed and power.

EFFECT OF SNOW ON THE TRACK.

In anticipation of severe snow storms, which occur so frequently in many parts of the United States, car No. 1 was fitted with a snow plow and wire brushes. This plow was ingeniously constructed; the shears were fixed to a balanced frame underneath the front platform of the car. Very little pressure on a stud, which could be moved up and down by the foot of the driver, brought the shears into contact with the rails. Immediately behind the plow-shears, and just ahead of the front wheels of the car, were brushes (made of stiff steel wires), and these were kept scraping on the rails by means of weights. The plow served the purpose of removing the bulk of the snow, and the brushes swept the rails and grooves clean in front of the wheel flanges. One day it snowed very hard, and when the rails were covered to about one-quarter of an inch we took this car out, using merely the wire brushes and a little sand on the steepest grade. The first round trip over this snowed up ground took 2 minutes and 8 seconds, but it cleared the track completely; the average current used was 50 amperes. Twenty trips were then made in succession, taking on an average 1 minute and 45 seconds, with a mean current of 30 amperes, snow falling hard all the time.

Then we allowed the snow to accumulate for four hours until it was about 2 inches deep; on starting the car, and during the first journey, the plow, the brushes, and sand had to be called into requisition. The current used averaged 80 amperes, and the time 2 minutes and 20 seconds; but each succeeding trip took less time and less current,

until it reached its normal value. This shows that with proper appliances, and with cars rapidly succeeding each other, the track can be kept clear; but the accumulation of much snow in the first instance occasions a fearful demand of energy, and without plow and brushes the snow is compressed by the wheels, and renders locomotion almost impossible.

On one occasion snow was shoveled upon the track 4 inches deep and beaten down; the car started with great difficulty, because the shears and brushes were practically buried; but with a skillful manipulation on the part of the driver, by going forwards and backwards a few inches at the start, and using sand from the automatic sand-box, provided for the purpose, the vehicle cleared itself and made its journey, slowly at first, gradually a little faster, until at last a tolerably clean rail was obtained by the traffic over it.

Without plow and brushes it is not only very difficult to make any progress through snow, no matter what power there be at disposal, but the car wheels are very apt to leave the track and ride over the compressed snow, which gets as hard as ice, when it can only be removed by the application of crowbars and scrapers, or a free use of salt.

A properly constructed ammeter will give more faithful indications than a dynamometer, and the minutest variations in tractive force can thereby be ascertained in an instant, since there is neither momentum nor friction of measuring instruments to be accounted for. By careful observations we were enabled to record the effect of various comparatively small obstacles upon the rails, and we have found that dry dust and snow virtually doubled and trebled the energy which was found necessary on clean or moist rails.

A simple calculation will show that there is no worse policy than economy in looking after the condition of tracks. The slightest attention to this requirement will show a very material saving of power. Tramway engineers know this to some extent, but they have evidently not found out the exact numerical value of cleanliness, otherwise they would be more particular. An electric car will run twice the distance with the same amount of energy on a clean wet rail that it will on a dry one with grooves full of dust. With storage battery cars, careful attention to the road will especially count, since the life of the cells can be more than doubled with half the rate of discharge. Considering the vital importance of these facts, we need not apologize for the rather lengthy treatment of this branch of our subject. By reducing the tractive resistance we can diminish the weight of the battery, or increase its durability, the cost of cleaning the rails will be more than recouped by the smaller depreciation of the plates, and the saving of propelling power may be taken as a clear gain.

(To be continued.)

ABSTRACTS AND EXTRACTS.

SCIENTIFIC RESEARCH.[1]

"In the early years after the foundation of the government a few great men were interested in the philosophy of science, in its facts, and in research. Franklin was a physicist, Jefferson a naturalist, and Gallatin an anthropologist. These and other great men of the time drank deeply at the fountain of science; but they were statesmen, or they had other callings and made the advancement of science a secondary purpose. But slowly scientific men rose, one after another, who devoted their entire energies to research. In the last generation a galaxy of great scientific men appeared in the American firmament; Henry, Bache, Pierce, the Rogers brothers, Gray, Baird, and many others. These men devoted their lives to research and instruction in science. In 1840 they organized the Association of Geologists and Naturalists, and in 1848 they transformed that society into the American Association for the Advancement of Science. Since that time the society has embraced in its membership all or nearly all of the scientific men of America, and in the list of its officers—presidents, vice-presidents, and secretaries—the names of many of the illustrious scientific men of the country are enrolled.

"Most of the great men of that generation have sailed away on the unknown sea. A few only, like Dana, Hall, Newberry, and Lesley, remain to guide in our councils and to cheer on the labors of the present generation of investigators. The society which they organized has grown with the growth of the country and the far more rapid growth of science, until it embraces a membership that constitutes a vast corps of laborers who occupy the border land of knowledge, which is the field of research. To enumerate in systematic order the fields of research occupied by the various members of this association would be to formulate a classification of the sciences.

"Atoms, mountains, and worlds, with all inorganic bodies and all inorganic motions, are to be examined in the study of the inorganic realm. The phenomena of nature are qualitative and quantitative, and out of quantitative relation the abstract science of mathematics has been developed, and this science of measurement is rapidly being applied to the qualitative sciences. There are many men engaged in mathematical researches. There are members who study the stars, compute their distances, and determine their courses, and who are seeking to solve the mysteries of the constitution of the bright sun and the pale moon: for on the chariot of light they drive through the storms of the greater orb and explore the dim fields of the lesser. Others with patient labor seek to discover the nature of light, of electricity, and of gravity—the mysterious force that impels the universe. There are others, many others, who are investigating the minute constitution of matter and determining its many forms. These forms are for ever changing. The crystals of the rocks that make up the mountain mass are dissolved and their atoms redistributed in new forms, and chemical changes are in progress wherever human investigation can penetrate. The tree grows and decays, and man is but a form—a mould, through which streams of atoms pour in waves of chemic change. So the chemist studies the laws which govern the constitution of bodies and under which they are for ever in flux. There are others who are studying the molar motions and mechanical powers by which waters are made to turn mills, winds to waft vessels, and steam to drag cars. There are others who study the atmosphere which bathes the earth. They study the coming and going of storms, where fierce cyclones are born, how the cold wave creeps from polar regions, and the hot wave from the tropics. There are others who are studying the surface of the earth—the lands and seas in all their places and forms. At the far North there is a region walled by ice, a million and a half square miles in extent; but even into this land of ice they penetrate. About the South Pole there is an area of seven million square miles enclosed by a barrier of ice—an unknown region into which the modern scholar is bound to enter. Between these walls the whole habitable earth is spread, and they are exploring all its seas, navigating all its rivers, climbing all its mountains, and threading all its cañons.

"A great army of men is engaged in the study of the constitution of the earth—the origin of mountains and valleys, of hills and prairies, of volcanoes and geysers, of cataracts and caves, and of rivers and lakes and seas. They examine the great coral reefs and islands of the sea, and they study the great coral rocks of the land—the fossil reefs and islands of ages gone by. Climbing among cliffs, they study the anatomy of dead volcanoes, and climbing to the brink of craters, they study the physiology of living volcanoes. If an earthquake rends the rocks, they measure the vibrations of its waves, and with the eye of science penetrate to the centre of the disturbance, and draw upon their maps the lines of weakness in the crust of the earth. They follow the sands that are washed by storms from the mountain sides until they find them built by the sea into islands and coasts. With microscope and crucible they study the constitution of granite, basalt, trachyte, and other rocks, wherein appear the crystal forms of many minerals. They show that the grand mountain form, with its crags, and peaks, and grottoes, where forests stand, where lakes are embosomed, and where cataracts flash in the sunshine, is indeed an aggregation of many gems beautiful in form and brilliant in color.

"But man is not satisfied with the knowledge which comes with the study of the inorganic realm; he essays to solve the mysteries of life. An army of men is engaged in the investigation of vegetable life. They find minute but beautiful plants that grow as dust on polar ice; in dank fields they find fungi, on rocks they find mosses, on the waves they find sea-weeds, on tropical trees they find orchids, on the prairies they find asters, in the savannas they find lilies, in the jungle they find palms, in the forests they find oaks, on the mountain flanks they find sequoias; and they study all these forms and a thousand more, and out of their study grows the science of botany. Then they must know how these forms became, and they trace their origin in the dim past, and they exhume the forms of plant life from the tombs of ancient meadows and groves.

"Then another army of men is engaged in the investigation of

1. From the address of Major J. W. Powell, Director of the United States Geological Survey, delivered as President of the American Association for the Advancement of Science at the Cleveland meeting, August 15.

animal life, and they find the land and sea teeming with varied forms. In the sea the coral animals grow and build their weird structures. On the bottom and shores of the sea mollusks crawl, carrying with them their pearl-lined homes. There are mollusks in all the lakes, in all the rivers, in all the brooks, and in all the ponds, and they wander over the lands and climb the trees. On the lands there are crawling worms, and in the seas crawling articulates, and the world is covered with crawling insects. The ants live in cities of their own building, the bees live on the clover blossoms, and the butterflies play among the roses. The fishes swim in the waters, the reptiles crawl in the marshes, the birds fly in the air, and the beasts roam over the land. These animal forms are studied and classified, and we have systematic zoölogy. But this is not all of zoölogy. In the life of every living thing there is a wonderful history of transformation; so zoölogists study the birth, growth, and death of animals. Then they discover the origin of present tribes, by investigating the forms of life that have existed in the past, and they call upon the rocks to reveal their evolution.

"Man essays to learn the marvelous structure of the human form, and the working of this complicated organism, and the processes by which the materials of the world are transformed into brawn and brain, and by which the powers of the dead universe are transformed into life. This study gives us the science of human biology. Having learned how men live, scholars seek to learn how men may live longer. In his quest to know, man has transformed plains into fields, prairies into gardens, forests into orchards, tribes of wild beasts into herds and flocks; he makes the cataract his slave, and laughs at the lightning; the multitude of enemies by which he was once surrounded have now become his friends; in his puissance he seems to have conquered all; but while he has subdued many of his great enemies, he is surrounded by hosts of infinitesimal foes. He fears no attack of the lion, but he surrenders in death at the attack of the microbe, yet by light of science he seeks to disarm and destroy these infinitesimal foes.

"Man is an animal in body, stomach, and legs; but then he is an animal with opinions, and forever he has been systematizing these opinions into philosophies. In the earliest philosophy everything was endowed with life and deified—stones, trees, fountains, forests, beasts, winds, waves, and stars; and the mysteries of the universe were explained by making all these things intelligent actors. From this, the earliest philosophy of the lowest savage, it is a long way to the philosophy of science, and there have been many stages. That hollow dome, the firmament, has become infinite space; the wind, that was at first believed to be the breath of beasts stationed at the four corners of the earth, has at last become the circumambient air in motion under physical laws; the flat space of earth has become a globe; astrology has become astronomy; alchemy has become chemistry; witchcraft has become medicine; beast gods have become domestic animals; and nature gods have become energies that can be used as the servants of man. The history of these opinions and of the philosophies into which they are woven is now a theme for the investigation of many men.

"So the members of this society are prosecuting investigations in the realms of motion, life, and mind; and there is such a division of labor that every great science included in these realms has its devotees. It is a goodly work, it is a grand work."

ELECTROLYSIS OF IRON SALTS.[1]

BY ALEXANDER WATT.

(Concluded from page 302.)

Persulphate of Iron and Sulphate of Potassa.—A weak solution of the persulphate was first obtained, to which was added a solution of sulphate of potash. With the current from four Daniell cells and large anode surface, a bright deposit of iron of a steel grey color was obtained upon a brass plate soon after immersion. The deposition was rather slow at first, until the anode surface was increased, and there was a good deal of hydrogen given off. After the plate had been in the bath about half an hour, a good coating of iron was obtained on both sides of the plate, and small crystals of metallic iron were found attached to one corner of the plate, showing that the deposition had really proceeded with some rapidity during the time.

Persulphate of Iron and Sulphate of Ammonium.—It was next determined to ascertain if the addition of sulphate of ammonia to a solution of the persulphate of iron would favor the deposition of the metal. For this purpose a dilute solution of the persalt was taken, and to this was added a small quantity of sulphate of ammonia, which was dissolved, with stirring, in the liquid. On immersing a brass plate in this bath—the current from three Daniells being used—it at once became coated with a film of iron of a darkish color, the upper portion of which was of a blue tint. The current being evidently too strong, a single cell was next tried, when a prompt deposit of iron of a dark grey was received upon a fresh plate. The solution was now diluted with water, and a new plate immersed, when the deposition took place more gradually, and indeed too slowly. Two more cells were now added, when the film upon a fresh plate was at first of a blue color, but after a few moments it became tolerably white, and was perfectly reguline and adherent, the deposit having taken place on both sides of the plate, proving that the solution was a fairly good conductor. I may say that this result somewhat surprised me, for although I had succeeded in obtaining metallic deposits from iron persalts from various solutions, *as a matter of fact*, I never expected that a tolerably good depositing solution could be formed from such salts; but this, so far as I have gone with this latter experiment, really appears to be the case.

Persulphate of Iron and Sulphate of Soda.—A solution was formed by adding to a rather weak neutral solution of persulphate of iron, powdered sulphate of soda crystals, a little at a time, and stirring the liquid until this salt was dissolved. With the current from three Daniells, a deposit of iron at once commenced to form on the corners of a brass cathode, the film gradually increasing until the whole of the immersed surface—about two square inches—was covered. The deposit, which was of a blue-grey color was very streaky and irregular; to remedy this, if possible, the bath was further weakened by addition of water, which somewhat improved the character of the film; but this, however, still remained patchy or mottled. The bath was again diluted, at which point it was exceedingly weak, but still yielded a prompt coating of iron upon a clean brass plate. To obtain a uniform coating, and to improve the color of the film if possible, the plate was now gently moved about in the bath—a large anode surface being exposed—when the metal deposited in a more uniform condition and of a good white color. The results thus obtained further indicate the direction in which we must steer if we wish to obtain metallic deposits of iron from solutions of its persalts, with or without the admixture of other substances, namely, in the direction of the pump. Extreme dilution of the electrolyte appears to be an absolutely necessary condition. Although solutions of the persalts of iron have no practical significance so far as relates to the deposition of the metal upon other metallic surfaces for the purposes of art, I was desirous, in these latter experiments, to ascertain, *first*, if iron could be deposited at all from any or all of these solutions; and *second*, under what conditions. In my first experiments with the persalts I was, in common with others, unsuccessful, and it was not until I had obtained an actual film of reguline metal from a pernitrate solution, that I became convinced of the possibility of reducing the metal from persalts provided the proper conditions could be arrived at. Those conditions I discovered after a very extensive and tedious course of experiments, and if I were to go over the same ground again I should exactly reverse the basis on which they were conducted; for, instead of commencing with a moderately strong solution of any given persalt, and gradually reducing its strength, as occasion required, by additions of water, I should start with a measured quantity of water, and to this would add, by small quantities at a time, a concentrated solution of the salt under trial, these additions being made until a film of iron appeared upon a clean brass or copper cathode.

Perphosphate of Iron.—Hydrated peroxide of iron was digested in a boiling solution of phosphoric acid, and the solution afterwards filtered and diluted with water. With a current from three Daniells a blue film of iron was first obtained upon a brass plate, but after a few minutes immersion the deposited metal acquired the characteristic color of iron, though not so white as that obtained from a solution of the protosalt.

Lactate of Iron.—A solution of this salt was first prepared by digesting a quantity of fine iron wire in a strong solution of lactic acid for many hours, when a pale green solution resulted, which, after moderate dilution, was electrolyzed with the current from three Daniells in series. There was a brisk liberation of hydrogen, and after a few minutes immersion of a brass cathode a film of iron of a somewhat dark color appeared upon its surface. No deposit could be obtained with a smaller number of cells than those mentioned. A solution of lactate of iron was also prepared by dissolving carbonate of iron in a strong and warm solution of lactic acid, and the liquid was used in its warm condition with the same number of cells, when a prompt film of iron was obtained upon a brass plate, but the color, as before, was of a dark color.

Perlactate of Iron.—A strong solution of lactic acid was first heated, and moist hydrated peroxide of iron then introduced in small quantities at a time, and the heat kept up until the acid was neutralized. The vessel was then set aside until cool, and the clear liquor, which was of a deep orange color, was afterwards decanted for use. With the current from three Daniells in series, a dark colored and somewhat iridescent film of iron slowly formed upon a brass cathode, and this was found to be firmly adherent. The solution was then gently heated, and tried with the same current, when the deposit was somewhat more prompt, and the color of the film improved, especially when the plate was slowly moved about in the bath.

In pursuing the experiments described in this and the preceding papers, my aim was to obtain deposits of metallic iron, if possible, from even the most refractory iron salts, and in this, I am pleased to say, I generally succeeded, by making such modifica-

1. From the *Electrician* (London).

tions of current strength and density of the electrolytes operated upon, as from time to time occurred to me. In arriving at more or less satisfactory results with solutions that presented much difficulty, I frequently had to make a very considerable number of trials before I succeeded in finding out the conditions necessary to obtain the desired film of iron of a proper reguline character. When these conditions were approached, further investigation was often necessary to ascertain whether further modifications would give still better results; and it was not until such additional trials had been made that I felt satisfied with the final result of my labor. From a practical point of view, I am fully aware that many of the experiments I have recorded will have but little interest. To the student of electro-metallurgy, however, the behavior of various solutions of metallic salts under electrolysis cannot fail to possess at least the interest which always attaches to fact. Indeed, when we consider the comparatively meagre information which has been furnished us by the various investigators of electro-chemical phenomena, concerning the electrolysis of metallic solutions other than those which have a more or less practical application in the arts, it would appear that further investigation should be made in this direction, and to this agreeable task I have for some time past—and purpose continuing to do so—devoted myself, believing that not only the student, but the practical electro-metallurgist, may derive some beneficial knowledge from the records of electrolytic experiments with a considerable number of metallic solutions.

If we consider the practical application of iron solutions in the electro-deposition of that metal upon other metallic surfaces, as in the so-called steel-facing of engraved copper plates, for example, I am disposed to give the preference to the following salts for making up iron baths, and if these are prepared with care, and from good materials, there should be no difficulty in obtaining good results from either of them. 1. The ammonio sulphate of iron. 2. Sulphates of iron and magnesia. 3. Sulphate of iron and chloride of ammonium. 4. Sulphate of iron *per se*. To prevent the solutions from becoming oxydized many different substances have been added to iron baths, as glucose (grape sugar), glycerine, &c.; but I am disposed to think, from experiments I made in this direction, that small doses of citric or tartaric acid will be found more effectual, while these vegetable acids have also a tendency to improve the brightness of the iron deposit. Again, in making up iron baths for the practical deposition of the metal, it is often recommended to employ an anode of large surface—that is, considerably larger than that of the article to be coated. I am disposed to suggest, however, that the strength of the solution and density of current should be so regulated that the metal will be deposited freely and uniformly with an anode surface about equal to or, at least, not greatly exceeding that of the cathode. My object in suggesting this is that I have found the metal to deposit well under such conditions from the solutions named, and such being the case, there can be no real advantage in greatly exceeding the limit of anode surface. A solution will, I believe, yield more uniform results and maintain its normal condition for a longer period if a uniform density of current be always maintained, and the liquid kept in such a condition that the iron will freely deposit when the electrodes are of about equal surface. To my mind it is generally a sign that the electrolyte is defective, or the current too weak, when a large anode surface is necessary to obtain a metallic deposit of good quality, and at a proper rate of speed to render the film adherent. In depositing iron from any of its neutral solutions great care should be taken, when lifting the article out of the bath to ascertain how the deposit is progressing, that the film be not exposed to the action of the air for any length of time, since the exposure of a few seconds only would be quite sufficient to form a film of oxide upon the surface, which would effectually prevent the subsequent layer of metal from adhering to the first. We all know, as I pointed out many years since, that metals do not adhere well to their kind when deposited by electrolysis; thus, gold does not firmly adhere to gold, silver to silver, and so on; but this is more remarkably the case in respect of nickel, which I believe cannot be made to adhere to the same metal by any electrolytic method whatever. I have been prompted to make the above observations in the hope that they may in some degree assist in guiding those whose inclination or duties may lead them to engage in the electro-deposition of iron upon other metals.

ALTERNATE-CURRENT ELECTROLYSIS.[1]

BY MM. J. CHAPPUIS AND G. MANEUVRIER.

THE impossibility of producing electrolytic decomposition of sulphate of copper by an alternating current is generally supposed to be an established fact. The absence of all electrolytic phenomena is explained by the assumption that the copper deposited by one current is immediately removed by the other. This negative result is even brought forward as a proof of the exact equality of the two currents. We, however, have been able to justify this explanation by rendering visible the electrolysis of the sulphate, as we have already done in the case of acidulated water.[2] The experiment is, however, somewhat more complex and more difficult to effect. If a concentrated solution of copper sulphate is placed in a voltameter with platinum electrodes, currents having an average strength of 2.5 amperes (which in the case of acidulated water produce an abundant evolution of explosive gas) give rise in sulphate of copper to nothing more than a considerable heating effect. But if the size of the electrodes is reduced to about 6 sq. mm. (0.1 mm. diameter, 20 mm. long), there is both evolution of gas and deposition of copper. Electrolysis succeeds equally well with copper electrodes of the same size. As soon as the circuit is closed, a column of minute gas bubbles instantly ascends amidst a cloud of red-brown powdery copper, whilst the electrodes soon assume the appearance of the freshly reduced spongy metal.

Taking all our experiments together, they seem to show that it is possible to establish a sort of equilibrium between the rate of decomposition and the rate of recombination of the constituents of the electrolyte. Once this equilibrium is attained, there seems to be no further electrolysis, properly speaking. Hence, all things which tend to make the rate of the former predominate over that of the latter will cause the reappearance of electrolytic phenomena, whilst those conditions which tend to make the rate of recombination predominant will cause these phenomena to disappear.

Current density is one of the principal things which tend to accelerate electrolysis. It is evident that if on the one hand we increase the quantity of electricity traversing the electrolyte, while on the other we diminish the surface of the electrodes, we shall cause the rate of decomposition to gain on that of recombination, and tend to produce electrolytic action. It is also easy to understand that both electrodes and electrolyte may greatly affect the rate of recombination by virtue of their chemical and physical properties. Hence the tendency to electrolysis depends upon the nature of electrodes and electrolyte, as shown by our previous experiments. Lastly, it can be foreseen that, all things being equal, the rate of alternation will play an important part in these phenomena. For supposing that the rate of alternation becomes so slow that the electrolytic products of one current have time to disappear, either by direct disengagement or by diffusion, before the products of the opposite current appear, it is obvious that no recombination is possible. In this case each current acts like a continuous current of short duration; thus, the slower the rate of alternation the greater the probability of electrolytic effects, all things being equal, and *vice versa*. We have been able to verify this theory by actual experiment. Employing, as we did, a separately-excited machine, we were able to vary the rate of alternation without affecting the average strength, and, consequently, the average density of the current. We altered the speed of the machine from 1,500 to 2,600 revolutions a minute, thus raising the number of alternations per second from 100 to 173, and by regulating the strength of the current flowing round the field magnets we were able to maintain a constant current. Under these conditions we carried out the two following experiments.

With the machine running at its proper speed of 2,000 revolutions a minute (133 alternations per second), we regulated the strength of the current so as to obtain a state of equilibrium, *i. e.*, a state in which no gas would be evolved in an ordinary water voltameter. We then lowered the speed to 1,500 revolutions (100 alternations a second), and gas was freely evolved at the electrodes. Next with the machine running at 2,000 revolutions and the current regulated so as to produce a remarkable and regular evolution of gas, we increased the speed to 2,600 revolutions (173 alternations a second), and the evolution of gas was immediately arrested. In either case it is possible to counteract the effect of this variation of speed by a proper modification of the current density. Thus, in the first experiment the gases were made to disappear again by increasing the surface of the electrodes; whilst in the second experiment the gas was made to reappear by reducing their surface.

We thus see that speed of alternation and density of current affect the question of electrolysis inversely, so that currents of medium density may give rise to electrolytic effects, provided the alternations are slow enough. It was owing to this that in 1837 de la Rive was able to decompose acidulated water by means of alternate currents from the then recently invented magneto-electric machines. He was able to get explosive gas on large platinum electrodes of eight square centimeters surface, so that the difficulty in his case was to get rid of the gases, while in our case the difficulty was to make them appear. This difference arises from the fact that the machine used by de la Rive gave at the most 50 alternations per second, whilst ours gave at least 100 alternations. From these experiments we shall be able to deduce the numerical laws of the several phenomena and the general rules which ought to guide the use of these currents for this purpose.

In a subsequent communication (*Comptes Rendus*, vol. cvii., No. 2) MM. Chappuis and Maneuvrier give an account of their

1. Translation of a paper by MM. J. Chappuis and G. Maneuvrier, read before the Académie des Sciences. (*Comptes Rendus*, vol. cvii., No. 1.) From The *Electrician* (London).

investigations into the causes of the spontaneous explosions of the mixed gases given off by alternate current electrolysis, and the means by which they were enabled to avoid this dangerous occurrence. The following is an abstract of this interesting paper:—

"If a voltameter of the ordinary pattern is used in alternate current electrolysis experiments an explosion inevitably occurs when all the liquid has been nearly expelled from the collecting tubes, and it was only after we had taken special preventive measures that we were able to continue our researches. This phenomena was observed by de la Rive as long ago as the year 1837, and also by Bertin in 1857. De la Rive passed alternate currents from an electro-magnetic machine through an ordinary water voltameter, and noticed that the platinum electrodes became coated with a powdery platinum film, and that if they were then introduced into a vessel containing explosive gases an explosion resulted. From this de la Rive concluded that the phenomenon was due to the so-called catalytic action. Bertin decomposed acidulated water by a continuous current from a battery of 50 Bunsen cells, and collected the evolved gases in the same receiver. He observed that the gases exploded as soon as the receiver became nearly full, both when platinum was used for either electrode and when platinum was used as the positive and iron as the negative electrode. With platinum and copper, or with platinum as the negative and some oxydizible metal as the positive electrode, no explosion took place. Bertin attributed the phenomena neither to catalysis nor heating, but to the "polarization of the electrodes" [an explanation which seems to leave a good deal to be explained]. Neither of these theories suffices to account for the facts as observed by us. Like de la Rive we observed the black film, but it has nothing to do with the detonation of the gases, since this often takes place long before the appearance of the film and when using perfectly new electrodes. Like Bertin, we produced explosions with other metals than platinum; but, unlike him, we came to the conclusion that polarization had nothing whatever to do with the phenomenon. For, take a new electrode and fill a bell-glass with the mixed gases, then substitute another new electrode,—the gases explode the moment the current is put on, provided only that the electrode is sufficiently well out of the water. We attribute these explosions to the electrodes becoming incandescent by reason of their progressive emersion from the liquid, increasing as it does the current density and the resistance, and diminishing the cooling effect due to contact with the solution. We have been able to make this incandescence actually visible.

"We take electrodes of platinum, which are placed in a bent tube. One end of the platinum is soldered to the copper wire conveying the current, the other end is soldered to the glass. We have noticed that the end soldered to the glass becomes incandescent at the moment of detonation. One of the electrodes having been broken, an almost invisible point projected out of the glass, and the moment the current was started this projection became incandescent, exploding the glass bubbles as soon as they came in contact with it. Again, if only the tips of the electrodes are allowed to dip into the liquid, incandescence and detonation are the immediate result."

It follows from this that all circumstances which tend to increase the heating effect, such as increase of current density and diminution of electrode surface, tend to accelerate explosion. Thus, with a .5 mm. wire, detonation did not occur until the gas had pushed down the liquid to within 5 mm. of the end of the electrode. On the other hand, with a 2 mm. wire, the explosion took place when the liquid was still 25 mm. from the end. To prevent explosion we keep the electrodes always well immersed in the solution by enclosing them in a conical or cylindrical funnel, at the top of which there is a small straight tube, which carries off the gases to a receiving vessel. This, or any other similar arrangement, is well adapted to obviate all danger in the manipulation of the explosive gases given off in alternate current electrolysis.

THE VOLTAIC BALANCE.

BY DR. G. GORE, F. R. S.

A NEW and simple lecture experiment. Take two small clean glass cups containing distilled water, simultaneously immerse in each a small voltaic couple composed of either unamalgamated magnesium or zinc with platinum, taking care that the two pieces of each metal are cut from the same piece and are perfectly clean and alike. Oppose the currents of the two couples to each other through a sufficiently sensitive galvanometer so that they balance each other and the needle does not move. Now dip the end of a slender glass rod into a very weak aqueous solution of chlorine, bromine, iodine, or hydrochloric acid, and then into the water of one of the cups. The voltaic balance is at once upset, as indicated by the movement of the needle, and may be shown to a large audience by means of the usual contrivances.

The chief circumstance to be noticed is the extremely great degree of sensitiveness of the arrangement in certain cases:— This is shown by the following instances of the minimum proportions of substance required to upset the balance with an ordinary astatic galvanometer of 100 ohms resistance, and with a Thomson's reflecting one of 3040 ohms resistance.

1. *Zinc and platinum with iodine.* With the astatic galvanometer, between 1 part of iodine in 3,100,000 and 3,520,970 parts of water.

2. *Zinc and platinum with hydrochloric acid.* With the astatic galvanometer, between 1 in 9,300,000 and 9,388,185 parts; and with the reflecting one between 1 in 15,500,000 and 23,250,000 parts.

3. *Magnesium and platinum with bromine.* With the astatic galvanometer between 1 in 310,000,000 and 344,444,444 parts.

4. *Zinc and platinum with chlorine.* With the astatic galvanometer between 1 in 1,264,000,000 and 1,300,000,000 parts.

5. *Magnesium and platinum with chlorine.* With the astatic galvanometer between 1 in 17,000,000,000 and 17,612,000,000 parts; and with the reflecting one between 1 in 27,062,000,000 and 32,291,000,000 parts of water.

Every different soluble substance requires a different proportion, and with unlike substances the difference of proportion is extremely great. With solutions of neutral salts the proportion of substance required to upset the balance is large; for instance, with chlorate of potash, a zinc platinum couple, and the astatic galvanometer, it lay between 1 part in 221 and 258 parts of water.

The degree of sensitiveness of the balance is usually greater the greater the degree of chemical affinity the dissolved substance has for the positive metal and the less it has for the negative one.

By first bringing the balance with a magnesium-platinum couple and the astatic galvanometer nearly to the upsetting point, by adding one part of chlorine to 17,612,000,000 parts of water and then increasing the proportion to 1 in 17,000,000,000, the influence of the difference, or of 1 part in 500,000,000,000, was distinctly detected.

ON THE CHANGE OF POTENTIAL OF A VOLTAIC COUPLE BY VARIATION OF STRENGTH OF ITS LIQUID.[1]

BY DR. G. GORE, F. R. S.

THIS paper contains a series of tables of measurements of the electromotive forces of a voltaic couple composed of unamalgamated zinc and platinum in distilled water, and in aqueous solutions of different strengths of the following substances:—potassic chlorate, potassic chloride, hydrochloric acid and bromine. The measurements were made by balancing the potential of the couple by that of a suitable thermo-electric pile (Birm. Philos. Soc., vol. iv., p. 130), through an ordinary astatic galvanometer of about 100 ohms resistance.

The following are the minimum proportions of those substances, required to change the potential of the couple in water:—potassic chlorate, between 1 in 221 and 258 parts of water; potassic chloride between 1 in 695,067 and 1,390,134; hydrochloric acid, between 1 in 9,300,000 and 9,388,185; and of bromine, between 1 in 77,500,000 and 84,545,000 parts.

With each of these substances a gradual and uniform increase of strength of the solution from the weakest up to a saturated one was attended by a more or less irregular change of electromotive force.

By plotting the quantities of dissolved substance as ordinates to the electromotive forces as abscissæ, each substance yielded a different curve of variation of electromotive force by uniformly increasing the strength of its solution, and the curve was characteristic of the substance. As the least addition of a foreign soluble substance greatly changed the "minimum point," and altered the curve of variation of potential, both the curve and the minimum proportion of a substance required to upset the balance of the couple in water may probably be used as tests of the chemical composition of the substance and as means of examining its state of combination when dissolved. By varying the strength of the solution at each of the metals separately a curve of change of potential was obtained for each positive metal, but not for every negative one.

.... IT is exceedingly rare for an absolutely original invention to be sufficiently perfect to be of immediate use.... .—*Silvanus P. Thompson.*

.... For the last four years very little has been done towards improving either the life or the efficiency of incandescent lamps.—*Marmaduke M. M. Slattery.*

.... There is no known reason why a cheap substance may not be found which will act on coal, and develop electric currents in place of heat.—*Willard E. Case.*

.... There is no gainsaying the fact that the transformer system has made tremendous way, and this would never have been the case had not the system possessed merits placing it before all others for the general distribution of electricity.—*J. Kenneth E. Mackenzie.*

LIGHTNING.[1]

BY S. A. VARLEY.

ALL who have read the published lectures on the protection of buildings from lightning, lately given by Professor Oliver Lodge, or who have had the advantage of hearing these lectures delivered, cannot fail to have been impressed with the scientific ability and deep learning Professor Lodge has brought to bear on so interesting a study.

Still these lectures seem to me to convey the impression that the behavior of lightning is involved in great mystery, and they have a tendency, I consider, to unsettle men's minds by conveying an impression that lightning discharges instead of uniformly obeying certain defined laws, as believed by Faraday and our older electricians, act irregularly and capriciously.

The feeling with which I rise from their perusal is that of an unsatisfied desire for more complete knowledge, and a wish that I could conveniently repeat Professor Lodge's interesting experiments, for there is an eloquence in the actual performance of an experiment which the fullest description ever fails to convey.

The subject of lightning discharges is one in which I have always taken an interest.

Many years since I devoted a great deal of time to studying its behavior in relation to telegraph circuits. The first observation of real importance was made by me in Turkey, in 1856, when the lightning struck the Constantinople and Varna telegraph circuit.

The submarine portion of this telegraph was connected to Constantinople by about 24 miles of suspended wire, and there were three stations.

The terminal stations were at Constantinople and Varna, and the intermediate one was in the English embassy buildings at Therapia, about 11 or 12 miles from Constantinople, on the immediate shore of the Bosphorus.

The overground wire passed outside the grounds attached to the embassy, and the connection with the embassy telegraph office was made by means of two lengths of submarine cable sheathed with galvanized wire buried in the grounds, and which formed a loop through the telegraph instrument. The total length of buried cable was about half a mile.

Now, as the Therapia station was an intermediate one, it may be suggested that there was no actual necessity for an earth connection there; but for reasons to be presently explained, there was an earth wire led into the office.

When I took over the charge of the circuit, I found this earth connection had been made by means of the orthodox earth plate, and I found also it opposed considerable resistance. I therefore made a soldered connection between it and the galvanized iron wire sheathing of the two lengths of buried cable, thinking, not unnaturally, that a metallic conductor half a mile in length buried in the ground would make a very perfect connection.

The embassy grounds were situated on a subsoil of rock, still there was a surface soil of some depth, and the grounds were well timbered with numerous large trees.

When the hot weather arrived and the ground became, as a consequence, thoroughly parched, I found, to my surprise, the half mile of buried cable made a very imperfect earth connection, and as the river was close at hand, I discarded it altogether and made another earth contact by burying a No. 8 galvanized wire under the esplanade of the Bosphorus and sinking a length of wire in the river.

Morse printing instruments, worked on the single current system, were used in connection with this circuit, and a current starting from Constantinople passed, as indicated by the arrows in the diagram, from the suspended wire through one length of buried cable, through the galvanometer indicator to the key lever, from the key lever through the back contact to the electro-magnet of the relay, through this to the second length of buried cable, and from thence to the suspended wire again on the other side of the loop. The earth wire was connected to a vertical spring mounted on the key board near to the handle end of the key lever, which made a passing contact with it in its downward and upward motion; the effect of the passing contact was to discharge directly to earth the greater portion of the statical charge acquired by the cable every time the battery was closed in the circuit.

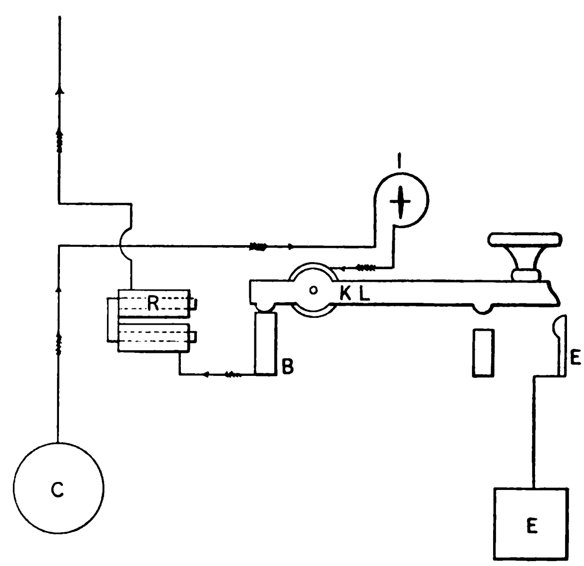
During a thunderstorm which occurred in the neighborhood of Therapia, the lightning struck the overground wire and passed through one length of the buried cable to the galvanometer indicator, leaping across the convolutions of silk-covered wire, burning them up, and bursting the indicator with a report as loud as a cannon, the current then passed on to the key lever which it lifted away from the back contact and depressed the front end of the key by electric attraction until it reached the earth contact, where it became fused and welded to the earth spring by the heavy discharge.

What I wish particularly to direct attention to is, 1. That this powerful discharge passed through one-quarter mile of gutta-percha covered wire buried in the earth without damaging it, showing how difficult it is under certain conditions to make a perfect connection with the body of the earth.

2. That although we know a lightning discharge to be instantaneous, the key lever was moved from a state of rest through a space of nearly one-quarter of an inch, and this movement *certainly* involved time.

I attributed the movement of the key lever to the magnetic polarization of the line wire by the lightning.

In other words, the effect of the lightning discharge was to produce during a very small interval of time a very high state of magnetic potential in the line wire, and the rapid reassumption of the normal unmagnetic condition which followed immediately afterwards developed a current of high enough potential to attract down the key lever, and of large enough quantity to melt and fuse together the key lever and earth spring. The current produced by the act of demagnetization of the line wire was undoubtedly assisted by the statical charge developed in a quarter mile length of buried gutta-percha wire, for although the resistance of the rock underneath the buried cable was so great that the lightning discharge did not burst through it and in this way reach the body of the earth, yet the large mass of semi-conducting matter surrounding the gutta-percha enabled it to receive a sudden charge, and as the iron wire sheathing outside the gutta-percha was a conductor of low resistance, the conditions were favorable for the rapid discharge of the electricity statically accumulated on the inner and outer surfaces of the gutta-percha insulator. The mass of earth and rock performed, in fact, a somewhat similar function to the slab of wood in some of Professor Oliver Lodge's experiments, which acted the part of conductor so far as to permit of the accumulation of a positive and negative charge



E, earth; I, indicator; R, relay; C, Constantinople; B C, back contact; E S, earth spring; K L, key lever.

in the interior of two Leyden jars, the outer coatings of which rested on the slab, and yet at the same time opposed so great a resistance that when a sudden discharge occurred the electricity leaped a space of air instead of passing through the slab.

It should not be, however, overlooked that a No. 16 copper wire coated with gutta-percha (for this was the size of the copper conductor) and only a quarter of a mile in length when considered as a Leyden arrangement was one of very inconsiderable surface, but still I do not think it should be disregarded altogether, and I have a further reason for referring to it, which can be perhaps more fittingly considered a little further on.

On my return to England I experimentally investigated the subject, and the chief conclusions arrived at were described by me in a paper read before the meeting of the British Association at Liverpool in September, 1870. The following passages appear in this paper:—[2]

"It was well known that high tension electricity would leap across a small space of air in preference to passing throughout the length of a coil of wire, and it was stated this arose from the momentary resistance the wire opposes to polarization or magnetization—a resistance probably approaching to infinite resistance during an infinitely small interval of time; and from this cause, even in a vacuum protector, where the pointed conductors are enclosed in an exhausted chamber, the main discharge will leap across a space of air separating the insulated conductor and the earth conductor outside the exhausted chamber, in preference to polarizing the wires entering the exhausted chamber. The

2. This paper was published *in extenso* in *Engineer and Engineering* in October, 1870, and an abstract of it was published in the "Transactions of the British Association."

author, when experimenting with electric currents of varying degrees of tension, observed the very great resistance which a loose mass of powder of conducting matter opposed to the passage of electricity of moderate tension; he found with a tension of 50 Daniell cells electricity did not pass through a loose mass of finely divided blacklead or wood charcoal. When the tension was increased to two or three hundred cells, the particles arranged themselves by electrical attraction, making good electrical contact, and formed a bridge by which the electricity freely passed. With a tension of six or seven hundred cells the electricity was found to pass through a considerable interval of the dust met with in rooms, which consists chiefly of silica and alumina, with more or less organic and earthy matters.

"Incandescent matter offers a very free passage to electricity; masses of highly heated blacklead powder were found with six cells to give an average resistance of five units, or about one-sixtieth of that opposed by an ordinary needle telegraph coil, which may be taken at 300 units. These experiments went to show that an interval of dust separating two conductors opposes practically a decreasing resistance to an increasing tension, and led to the construction of the "lightning bridge," which consists of two pointed conductors, enclosed in a chamber, and approached to within one-eighteenth of an inch from one another, and surrounded with finely divided matter consisting of carbon and a non-conducting substance intimately mixed in suitable proportions determined by electrical tests. The reason why a powder consisting entirely of conducting matter cannot be safely employed is, that although it may oppose a practically infinite resistance to the passage of electricity of the tension of ordinary working currents, when a high tension discharge occurs, the particles under the influence of the discharge generally arrange themselves so closely as to make a conducting connection between the two points of the lightning bridge.

"If the effect of lightning striking the wires be considered, it will be seen that the electric discharge passing through the telegraph coils is not momentary, but occupies time. When an insulated telegraph wire is struck, the effect of the discharge is to polarize the wire throughout; after the discharge the wire returns to its normal unpolarized condition; but the cessation of magnetization, although rapid, is not instantaneous, and the effect of the wire reassuming its normal unmagnetic condition will be to develop an electric current flowing in the same direction as the electric discharge which magnetized the wire. The tension of the current developed by the demagnetization will be very high at its first development, and will rapidly afterwards fall to zero. There is, therefore, first the main discharge of electricity, which passes by the shortest route, and does not wait to polarize the coil wires, but leaps across a space of air to the earth conductor as the easier course, followed by a secondary current in the same direction, but occupying time. The tension of this secondary current, although at first very high, is not nearly so great as the lightning discharge, and the greater portion, if not the whole, will pass through the coils, which oppose, when time is given, a much less resistance than the smallest possible space of air; it would, therefore, seem, when telegraph circuits protected by an ordinary protector are struck by lightning, it is to the secondary current, and not to the main discharge, the fusion must be attributed. The fact that the coils of needle telegraphs are more often fused than other telegraphic apparatus was considered to be a strong confirmation that the fusion was due to the secondary current developed by the demagnetization.

"The relay coils used in other telegraph systems have soft iron cores which are rendered magnetic when a current is passed through the coils. A greater amount of magnetism is developed in these cores than in needle telegraph coils, but a very sensible time is occupied by the iron passing from the normal to a magnetized condition. The momentary resistance these cores oppose to magnetization is very great; the demagnetization of the line-wire proceeds, therefore, more slowly; the electricity generated by the demagnetization being of a definite amount, the tension of the secondary current is reduced proportionally.

"The line wire of a telegraph circuit is *only a continuation of the coil wires, and is rendered magnetic by electric polarization in the same way as the coils*, the chief difference being that the magnetism developed in the coils is concentrated in a smaller space.

"When lightning strikes the line-wire of a circuit, in which electro-magnets protected by an ordinary protector are used, it magnetizes the line-wire, leaps the space which separates the points of the protector, and *does not magnetize the electro-magnets*. Demagnetization of the line-wire, which always takes time, and which can be retarded, follows, and the resistance which the soft iron cores oppose to the assumption of magnetization, retards the demagnetization of the line-wire, reducing the tension of the secondary current. In needle-telegraph coils, there being no large mass of iron to be magnetized, demagnetization of the line-wire follows much more rapidly; the secondary current is more intense, and consequently needle coils more often suffer."

I further state in another part of the paper I have quoted from:—"The retardation which the magnetization of an electro-magnet opposes to the *demagnetization* of another one is well known, and is explained in Culley's 'Handbook of Telegraphs,'[1] in connection with the description of C. F. Varley's translating system. The author refers to it because he is most anxious to advance only that which is the result of his own direct experiment, or is based upon well-established laws generally accepted by leading electricians."

The quotations given from my paper of 1870, demonstrate, I consider, that what is now known as self-induction, and on which so much light has been thrown by the researches of Professor Hughes, is in itself no new discovery, and I further think it may be fairly claimed for me that I grasped its significance. Professor Hughes' experiments were all made, I believe, on short conductors. My first observation of it was made on a much grander scale, and I think the conclusion I came to—that it is a consequence of the magnetic polarization of the conductor—is the more correct explanation, and if this be so, then the term magnetic inertia might be substituted with advantage, in my opinion, for the term self-induction, as more correctly indicating the source of the phenomena. Magnetism in its relationship to electric motion I have been disposed to consider, now, for some years, as the analogue of ordinary inertia, for it seems to me to resist the electrical motion of the atoms of matter among themselves inside the conductor in a precisely similar manner as ordinary inertia resists the motion of matter bodily.

In 1862 I made the observation that if a galvanometer were wrapped with two wires side by side of the same gauge and adjusted to have the same resistance, that when a battery circuit was closed through them one of the wires had invariably a greater influence on the magnetic needle than the other.

And I found the only way of producing a perfect differential galvanometer with exactly the same number of convolutions in both the insulated wires was to make them of wire drawn down from the same sample of copper, and this experience led me to commence the construction of apparatus to try experiments on what I called the magnetic moment of metals. I proposed to charge a paper condenser with 500 Daniell cells, and to discharge it through single straight conductors of various gauges and different metals, mounted between upright terminals in the neighborhood of a delicately suspended astatic needle carrying a mirror. I was prevented at the time from carrying out these experiments, and the opportunity has never occurred since. But what I had already learned from my observation of the lightning discharge in the neighborhood of Therapia, and my experimental investigations in connection with it, justified me, I considered, in anticipating that a conductor of small gauge would produce a greater deflection of the magnetic needles than a conductor of a larger gauge. I regarded the difference of resistance of the conductors with the high potential and mode of conducting the experiments as a negligible quantity. My reason for anticipating a wire of small sectional area would produce a greater deflection than one of larger size was that there would be less magnetism developed locally, and therefore there would be more free force to act on needles outside.

I should be glad even now to carry through these experiments; but I am disposed to think that the researches of Professor Hughes and Professor Lodge indicate to a considerable extent what would be the results likely to be obtained.

Some few years ago I had the pleasure of showing Professor Hughes some magnetic experiments, when he immediately demanded of me how I explained the action of a magnet through space. I replied that in my opinion the force was communicated in a precisely similar way as through a bar of iron, in other words, that there was a chain of matter, or some entity equivalent to matter, which connected the magnet, and the body acted upon through what we call space, and I said I ventured to go farther than this and say that where there was no matter there was no magnetism, no electricity, nor force of any kind, and I was glad to find the views I held coincided with those of Professor Hughes. If we assume magnetic inertia to be the analogue of inertia of matter regarded in the mass, then given a similar sectional area and shape in the conductors the magnetic inertia of each conductor would be perhaps expressed in terms of its electrical resistance; or to put it more plainly, if we regard magnetic inertia as the analogue of the inertia of matter regarded in the mass, then the specific resistance of the conductor would possibly represent its weight or resistance to electrical motion.

Iron and the magnetic metals would be the densest of substances if expressed in terms of magnetic instead of terrestrial gravity, and they would not seem to follow the law I have suggested.

Since the above passage was set in type, I have referred to Professor Hughes' presidential address to the Society of Telegraph Engineers, which, I am sorry to acknowledge, I have never given that attention to which its importance deserves, and I find his experiments go to show that self-induction is not related in any way to the specific electrical resistance of the conductors. I have not, however, withdrawn the passage, because I think I am generally correct in my contention that the inertia which is manifested by a soft iron core around which an electric current is cir-

1. Third edition, page 210, published in 1868.

culated, and the inertia manifested in the conductor itself, are referable to a common cause, the only difference between them being one of degree. I cannot help thinking that among our scientists of the present day there is far too great a tendency to elaborate and coin new phrases, whereas the aim should be to simplify and to link all phenomena and apparent anomalies observed to the common cause from which, if we could but see it, they most probably emanate.

The analogy between magnetic and terrestrial gravity appears to me to be so very complete; as an example, I might refer to the well-known fact that if a large mass of matter be suspended in space, a continuously applied force, however small, will, after overcoming the inertia of the mass, set it in motion; so also will a continuous current of electricity develop and maintain much or little magnetism accordingly to the length and mass of the electrical conductor and the mass of iron subjected to its influence.

In all dynamos, but more especially in shunt-wound machines, advantage is taken of this; and in some of the best examples the energy diverted in maintaining the magnetic field, as well as that consumed in the armature, is as low as from 3 to 5 per cent. If the analogy existing between magnetic inertia and material gravity, to which I have directed attention, can be shown to be complete, its scientific importance can scarcely be overrated, as it would place an instrument of research into our hands which would enable scientists to arrive at a fuller knowledge of the nature of gravity, a force, situated as we are in respect to it, so difficult for us to investigate.

Ever since I had the good fortune to discover the dynamo principle in 1866, I have striven to obtain a fuller explanation of it by studying the nature of the forces as a whole.

Our scientific professors appear to me to have been satisfied to accept this discovery without comment, and to regard the matter as explained when they say it is simply the conversion of one force into another. No one seems to have cared to ask the question how it is that by the expenditure of mechanical force in a machine, a fulcrum can be developed in the machine itself which resists the motion of the machine with a force proportionate to that which has created it, and accounts for such resistance by transmitting its equivalent in the form of energy through an electrical conductor.

In the discussion at the Institution of Civil Engineers, in January, 1878, which followed the reading of Messrs. Higgs and Brittle's paper, I called attention to this point, and stated, I attributed the creation of electrical energy in a dynamo to magnetism being a force possessing inertia, and electricity being a force having little or, as I believed, no inertia. That it was the inertia of magnetism which created the fulcrum, and as a consequence of this inertia, when a dynamo was in action, electricity was developed *instead* of magnetism.

I stated I was led to take this view from an observation made shortly after I had constructed the first self-exciting dynamo.

I had designed a magneto step-by-step alphabetical telegraph, in which simplicity of mechanical construction was obtained from the employment of a very powerful field produced by permanent magnets, and I observed there was perceptibly very much less resistance to the revolution of the handle when the circuit was closed, and electricity consequently developed, than when the circuit was opened and no force was being transmitted.

At the first blush, the fact that less force was being consumed when electric force was being transmitted appeared to be very anomalous; but after thinking over the matter, and sleeping on it for a few nights, I obtained the key to the solution of the problem, viz., that when the circuit was open I was magnetically polarizing the armature cores and overcoming the inertia of magnetism, which may be likened to transmitting a given quantity of force through a circuit of very great resistance, and when the circuit was closed I was developing, in place of magnetic polarization electricity, a force having but little if any inertia, and transmitting it through a circuit of very moderate resistance. When currents are developed by an alternating machine, the iron cores of the revolving bobbins in their passage between the opposite magnetic poles through which they pass in succession, if magnetized at all, are magnetized only to a small degree, electricity being developed instead of magnetic polarization. A little reflection will show it cannot be otherwise, for were magnetism developed in the revolving armatures, the force would be consumed in the machine itself, and there would be no energy to be transmitted beyond the limits of the machine.

I would here point out what is *commonly* termed the conversion of one force into another is not work, and consequently does not consume energy. Were it possible to obtain conductors having no electrical resistance, then the whole of the mechanical force consumed in giving motion to the machine would be transmitted in the shape of energy, and no force whatever would be absorbed after the magnetic inertia had been overcome in keeping up the motion of the vehicle or medium through which the energy is transmitted. I have said in the sentence immediately above, what is *commonly* termed the conversion of energy, for I am disposed to doubt whether there is such a thing as the conversion of force of one kind into force of another kind. I am disposed to attribute what is termed the conversion of force to the balancing of one force by another force, or the balancing one form of energy by another form of energy, and it is in such matters as these that mathematical science is so misleading.

To the mathematician energy is an elementary entity, and when energy at one end of the chain disappears and its equivalent is manifested at the other end he regards it as a full and complete explanation.

I may explain what I mean, perhaps, more clearly by a familiar illustration. A customer goes into a shop to purchase a joint of meat; the butcher places the joint in the scale pan and balances it by means of a weight. Expressed in terms of gravity the meat and the weight are the equivalent of one another, and in a mathematical equation they are convertible terms; but I think it is quite possible, from the customer's point of view, they are not one and the same thing, and he would not be satisfied if the butcher were to send home the weight in place of the meat.

The development of electricity in a dynamo I regard as being produced in a somewhat analogous manner to what would occur if a mass of matter were bombarded with bullets discharged from a rapidly firing machine gun; the motion of the bullets would be arrested and converted into heat. The simile would be more complete if we assume the revolving armature to represent matter bombarded on opposite sides, and the field magnets as matter bombarded on one side. I cannot resist the temptation to say a few words in respect to the Pacinotti armature in reference to its bearing to magnetic inertia, for I think it has never been done justice to in scientific treatises, nor does it seem to me that its *modus operandi* has been wholly grasped by our scientists.

I regard the Pacinotti armature in its theoretically more perfect form of the Gramme ring as being the most beautifully complete of scientific inventions. What I have never seen explained nor even suggested is the fact that both the magnetic as well as the electrical polarization developed in one part of the ring is balanced by that developed in other parts, consequently there is no force consumed in the magnetization of the armature, and it may be revolved in an active magnetic field, providing the collecting brushes are raised without consuming any force whatever; and, further, the commutation of the currents developed in alternate direction in the coils of the armature is performed in a perfect and natural manner by the revolving ring, which is, in fact, its own commutator. In an alternating current machine the magnetic polarization that occurs in the armature cores is so much force diverted and lost.

What takes place when a Gramme ring having no electrical circuit is revolved in an active magnetic field is very similar to what occurs when a disc is revolved rapidly, the particles of matter composing the disc are put into a state of stress by what is very unscientifically termed centrifugal force, for it is simply a consequence of continuously acting on force (which can only move in straight lines) by a second force and so altering its direction that the force developed on one side of the centre of motion is in all parts of the disc balanced by the force on the opposite side being in the reverse direction, and, therefore, the disc as a whole is in a state of equilibrium, although the matter composing it is more or less in state of stress.

(*To be continued.*)

ON THE TESLA ALTERNATING CURRENT MOTOR.[1]

BY J. SWINBURNE.

THE account of Mr. Tesla's invention has received such attention from the technical press, and appears to have satisfied so many people that the problem of alternating current motors is solved, that a short investigation of the subject may not be amiss.

The problem of alternating current motors may be divided into two distinct parts—to make a motor that will start, and to make a motor that will work with varying loads, preferably with constant or nearly constant speeds, but certainly with reasonably high efficiency in each case. As those who are accustomed to the usual way of treating dynamo problems will perhaps find a little difficulty in following Mr. Tesla's description, an attempt will be made to describe his apparatus another way.

Suppose an alternating current dynamo, such, for instance, as the Westinghouse, were taken, the armature has, roughly speaking, only half its periphery covered with wire. If another circuit were wound on, filling up the air spaces, it would also give an alternating current if it had its own collectors, but this alternating current would be a quarter of a period behind the other. The same effect would be got by rigidly coupling two alternate current machines together so that one is a quarter of a period in advance of the other—that is to say, one has its coils in a maximum field when the others are in their minimum field. The simplest form of such a motor would be an ordinary drum armature wound with two coils at right angles, each coil having its own pair of collector rings. This is the example taken by Mr. Tesla. The magnets, of course, are supposed to embrace a quadrant each, instead of about 150 degrees, as is usual in continuous current

1. From the *Electrician* (London).

machines. For simplicity we will suppose the generator to be made up of two ordinary alternating current machines, coupled rigidly together as described, with two pairs of conductors, each with its own alternating current, these currents differing by a quarter of a period. If a motor is made up in a similar way by coupling two alternate current machines together, if once started it will run in exactly the same way as an ordinary alternating current motor, having all its advantages and disadvantages, with the addition that it needs two sets of leads and a special generator. Its efficiency is the same as an ordinary motor, and it will synchronize in the same way. Of course it will not start.

Suppose now that the alternating motor is varied in construction so that the armatures are stationary, the effect will be just the same. A synchronizing motor will be obtained which is not self-starting. Instead of this Mr. Tesla uses what he calls a fixed field magnet with a rotating field and rotating armature in his motor, but we may perfectly correctly call it a fixed armature and rotating field magnet. The armature is outside the field magnet, and may be looked upon as a Gramme ring wound with four coils, the opposite coils being pairs, so that there are two circuits. One is connected to each pair of leads. The direction of magnetization is thus made to revolve just as in any alternate or direct current machines in which the armature is fixed and the field revolves, such, for instance, as the Ayrton and Perry motor or new Siemens dynamo. So far the only result is no better than can be got from machines already known.

As to the exceedingly ingenious method of starting, suppose in an ordinary dynamo an armature is revolved, having some short-circuited coils, the armature resists the motion owing to the currents induced. The armature is revolving, and the direction of magnetization is fixed; but, as motion is relative, we may say that the direction of the magnetization and the closed coils are moving relatively to each other. This relative motion is opposed by the currents induced in the coils. Now, if Mr. Tesla winds some closed coils on what he calls his armature, and what is here called his field-magnet, when the direction of magnetization moves round relatively to the closed coils, currents are induced which tend to make the field magnet revolve.

This ingenious method of making it start is the only advantage Mr. Tesla's motor possesses. In the synchronizing form the closed coils of the field magnets are used till the proper speed is attained, when the machine falls into step, and the exciting current is switched on, so that they become the field magnet coils in the ordinary sense. In another form the whole motive power is supplied by these closed coils, so that the machine does not actually synchronize, but goes slower at heavy loads.

Taking the first form, or synchronizing motor, we get a self-starting motor, but it needs an exciter, and needs also a special dynamo to drive it, with two circuits, involving three or four leads. In the second form the revolving part cannot be so well described as the field magnet, because it is excited entirely by the armature. Of course an ordinary direct current dynamo will work as a motor without any field current if the brushes are put forward, the field being then excited by the armature current; but to make such an arrangement efficient, apart from the question of sparking, which does not now concern us, the armature would have to be designed so as to magnetize the field strongly. In Mr. Tesla's arrangement this is impossible unless the machines are of enormous size. This difficulty would be lessened by making both the fixed and revolving parts on the Pacinotti principle. Instead of using two closed coils on a smooth core, there would also be an advantage in simply encasing the armature in solid copper.

The low efficiency is not at all the chief objection to the scheme. The whole arrangement is unpractical, as it demands special alternate current generators and leads. There are several ways of starting alternate current motors. The exciter may have laminated field magnets, and may be put on the alternate current circuit to get up the speed, as already proposed by the writer, or a small secondary battery may be used in connection with the exciter, which will start the whole system. It would never be worth while to put down special dynamos and special leads just to use a motor that will start, and that has no other advantages. The two circuits would be useless for other purposes. The transformer proposed by Mr. Tesla must be very inefficient. It has consequent poles revolving, and has thus an open magnetic circuit. It would be better to use the two alternating currents separately, putting some of the transformers on one circuit and some on the other; but if two circuits are to be used it would certainly be cheaper to use a direct current for the motors, and have them self starting, self-regulating, and efficient. Until Mr. Tesla can produce a motor which will work on alternate current circuits as they are, and do that efficiently even with varying loads, and without difficulty in starting, he can hardly be said to have solved the problem. With the ingenuity he has already shown no doubt he will do it soon, but he cannot be said to have done it yet.

.... The electric motor absorbs electricity in nearly a direct ratio with the work put upon it, giving practically the same efficiency with light and heavy loads.—*Frank J. Sprague.*

ENGLISH VIEWS ON SOME RECENT PATENT DECISIONS.

THE RECENT ELECTRICAL PATENT CASES.[1]

The judgment delivered by Mr. Justice Kekewich on Monday, the 9th inst., in the action between Messrs. Gaulard & Gibbs and Mr. Ferranti, is tantamount to a declaration that there shall be no monoply in the distribution of electrical energy from a central station by means of alternating currents. Had the verdict been given in the opposite sense, it would, strictly speaking, not have precluded electrical distribution by alternating currents as a general system, but only that particular arrangement in which transformers are used. As, however, only this arrangement is, in the present state of our knowledge, of any practical advantage, the monopolizing of transformer distribution would in effect be equivalent to the monopolizing of alternating currents for central station work, and there can be little doubt that such a monopoly would have formed a further deterrent to the electric lighting industry, which is already struggling with enough difficulties, not only legal, but also technical and commercial. However much we may sympathize with Messrs. Gaulard & Gibbs, whose pioneering work in this direction has thus failed to obtain legal support, we cannot disguise the fact that, by breaking down the monopoly which they attempted to establish, Mr. Ferranti has rendered an enormous service to the electrical engineering profession at large, and the decision of Mr. Justice Kekewich is consequently received with satisfaction by the majority of electric light engineers. It might perhaps be urged that to give Messrs. Gaulard & Gibbs the exclusive right to transformer distribution need not necessarily retard the progress of electric lighting, for these patentees would find it to their own interest to grant licenses for certain localities. It would obviously be impossible for the owners of the Gaulard & Gibbs patent themselves to carry out every installation in Great Britain which may be put down on their system; and to obtain the greatest benefit from the control of the patent they would naturally look to the granting of licenses, fixing their fees sufficiently low to induce the largest possible number of consulting engineers to recommend it, and contractors to carry it out. In theory such an argument is plausible enough; but in practice it is entirely fallacious. The fallacy lies in the assumption that one and the same system of distribution is applicable to all localities, and that in any one locality only one system need be adopted. The great object of a company starting an electric light station is to earn money by the sale of electrical energy, and to attain this object they must be prepared to supply this energy in exactly that form or variety of forms demanded by their customers. An electric light company should not restrict itself to one particular system; it should, if the demand is sufficiently great, be prepared to supply electricity in any form, whether by the direct low tension system, the direct high tension arc light system, by accumulators, or by alternate current transformers. All these systems are useful in certain cases, and to restrict the choice of system in any way is equivalent to curtailing the earning power of the station. If Messrs Gaulard & Gibbs had a monopoly of distribution by transformers they would have to parcel out Great Britain into districts, to be taken up and worked under license by different electric lighting companies. There would be endless complications about overlapping of districts and want of coincidence between the boundary as defined by the Gaulard & Gibbs' license and that imposed by municipal and other local considerations. The consulting engineer, when advising his clients whether to adopt the Gaulard & Gibbs' system or not, would have to consider a variety of points quite foreign to the scientific and technical parts of the problem, and to escape incurring responsibility in matters outside his professional control, would, in most cases, advise to leave the monopolized system alone, and adopt one in which his hands would be free to do the best he can for his clients. We may, therefore, set aside the argument that a monopoly in distribution by transformers would not necessarily restrict the development of central station lighting.

On the other hand, we doubt very much whether the loss of their patent will in reality prove disadvantageous even to Messrs. Gaulard & Gibbs themselves. To them undoubtedly belongs the merit of having been the first to show distribution by transformers in practical operation in England, and this fact cannot fail to invest their company with a considerable amount of prestige. There will be no lack of work for a company who is so favorably situated, and it is quite possible that by doing this work the company will fare better than if they had succeeded in establishing their monopoly.

Messrs. Gaulard & Gibbs will, of course, appeal against the decision of Mr. Justice Kekewich. Patent cases are seldom abandoned after having passed the first tribunal; and as the case will thus again come before the courts, we shall abstain from discussing the validity of the claims in the Gaulard & Gibbs' patent at present. As far as the case has already been argued in court it affords, however, a very instructive illustration of the masterly way in which apparently intricate and abstruse problems are

1. From *Industries* (London) July 20.

grasped and dealt with by legal minds. There are many trained electricians to whom questions connected with alternating currents and transformers present almost insuperable difficulties, yet the judge and counsel appeared to have thoroughly mastered the subject so far as this was necessary for a just appreciation of the various patent specifications which were put in. To a lay mind, the strongest argument in favor of the revocation of Messrs. Gaulard & Gibbs' patent would naturally appear to be that based on anticipation by Jablochkoff, Harrison, Fuller, Bright, Deprez, and others; and as regards Deprez, Mr. Aston conceded that his clients would not raise any objection if Mr. Ferranti worked according to that specification. Now the specification describes a system in which a machine produces a low tension current of large quantity which is converted at the station by means of a transformer into a high tension current of correspondingly diminished quantity. This current is sent out to the district to be lighted, and then reconverted into a low tension current. Curiously enough, this is precisely the system which Mr. Ferranti is adopting for his large central station at Deptford, and, according to Sir William Thomson, it is probably the best system which could be adopted for large stations, as thereby the great difficulty of insulating for excessively high tensions in the dynamos is overcome. Whatever may have been the weight of arguments based on the question of anticipation, Mr. Justice Kekewich did not enter into this part of the case, but gave his decision simply on the Gaulard & Gibbs' patent as amended, and as if it stood alone.

He said that a combination claim can only be upheld if each of the elements entering into the combination is fully and specifically described; but as there is nothing in Messrs. Gaulard & Gibbs' specification to show what special form of secondary generator is meant, and as indeed there is nothing special about their secondary generator, the claim is bad.

Whilst thus Mr. Justice Kekewich last week decided that there shall be no monopoly in alternate current distribution, Mr. Justice Kay, on Monday of this week, came to a similar decision in regard to glow lamps. We have from time to time reported the proceedings in the famous case of Edison and Swan *vs.* Holland, which has occupied the court for 22 days, and is probably the longest patent case on record. It will be remembered that on the suggestion of the judge a series of experiments were made to demonstrate practically certain of the statements made by expert witnesses, and to show whether a commercially successful lamp could be made by following the directions given in Edison's specification. Having taken time to consider Professor Stokes' report describing these experiments, Mr. Justice Kay delivered judgment on Monday last. This judgment shows perfect mastery over the whole subject, and is in itself a most interesting and complete summary of the development of the glow lamp up to the year 1878.

His Lordship decided broadly that Edison was not the inventor of the incandescent lamp, that Edison did not discover any useful principle, that the only thing he did, or attempted to do, was to make a carbon thinner than those then in use. He also decided that the patent was bad because it was of no commercial use. Edison lamps made under that patent were never sold, and the so-called Edison lamps were made under subsequent patents, not under that in question. The patent was also bad because the specification did not give instructions by which a lamp could be made, and also because it gave misleading instructions or misdirections. To say that Edison invented the incandescent lamp was monstrous. Neither Edison, Swan, Lane-Fox, nor anyone else invented the incandescent lamp. It is a gradual growth. It has developed by stages, generally slow, beginning about 50 years ago. Latterly it has developed more rapidly owing to the impetus given to electric lighting by the advent of commercial dynamo machines, and it will now develop still further. Many men have worked out important details, and Edison deserves honorable mention among them, but that is all that can be said. The daily press appears to regard Edison as the one and only electrical inventor, but such views find no sort of reflection in technical circles. We are glad of this decision, because it breaks down one of many prejudicial monopolies. The Edison patent, though by far the most important, was not the only one which figured in this action. The defendants were also sued on the Cheesbrough patent. This was said to cover the process of "flashing" now used by all incandescent lamp makers. This process is of great commercial utility, as it admits of making the lamps of any desired resistance. The defendants argued that it was invalid on several grounds, but Mr. Justice Kay held that the defendants infringed it, and that it was a valid patent.

We do not intend to go deeply into the legal questions involved in the action, nor do we think it advisable to discuss the complicated technical evidence given; but we may deal with the broad results of the action, and their effect on the electric lighting industry. The result of the double decision is this: Anyone can now make lamps, but he is debarred from using a process of great commercial convenience. If both patents had been declared invalid, no doubt there would have been a flood of cheap lamps, as it is needless to say modern lamps can be made for about a shilling each, or less. It might have taken a little while before English makers, except the Anglo-American Brush Co. and Messrs. Woodhouse & Rawson, could manufacture so cheaply; but the various foreign, and perhaps American lamps, could have been put on the market at once. The result of the Cheesbrough decision will be to prevent the importation of lamps, as it will not be worth while for a foreign maker to overcome the difficulties in making unflashed lamps commercially. These difficulties will also deter small makers in this country, so we may expect the manufacture will still remain in the hands of a few. Though this will prevent a flood of cheap lamps, it is probable that competition will improve lamps gradually and will cheapen them in time. It must be remembered that cheap lamps or better lamps do not mean only a saving in lamp bills, but also the cheapening of electric lighting; for lamps can then be run brighter, so that more light is obtained to the horse-power; that is to say, the takings of a station may be enormously increased without any increase of plant or labor. A very small improvement in lamps would convert a loss into a large profit in a central station.

Of course the Edison-Swan company may appeal as to the Edison patent, and the defendants may appeal as to the Cheesbrough. We think, however, that nothing would be gained on either side, as the Edison patent seems hopelessly invalid, and the Cheesbrough patent has had three judgments in its favor.

INFLUENCE OF THE CHEMICAL ENERGY OF ELECTROLYTES UPON THE MINIMUM POINT AND CHANGE OF POTENTIAL OF A VOLTAIC COUPLE IN WATER.[1]

BY DR. G. GORE, F.R.S.

By means of a zinc-platinum voltaic couple in distilled water, with its electromotive force balanced by that of a suitable thermo-electric pile[2] (Birm. Philos. Soc. Proc., vol. iv. p. 130), the effect of several groups of chemical substances upon the potential of the couple was examined. Measurements were made of the electromotive forces of a series of strengths of solution of each substance, and the results are given in a series of tables.

The minimum proportions of substance required to change the potential of the couple in water were as follows:—

Potassic iodate.	Between	1 in	443	and	494
" bromate.	"	1 "	344	"	384
" chlorate.	"	1 "	221	"	258
Potassic iodide.	Between	1 in	15,500	and	17,222
" bromide.	"	1 "	66,428	"	67,891
" chloride.	"	1 "	695,067	"	704,540
Iodine.	Between	1 in	3,100,000	and	3,521,970
Bromine.	"	1 "	77,500,000	"	84,545,000
Chlorine.	"	1 "	1,264,000,000	and	1,300,000,000

On comparing these numbers we find that the proportion of substance required to upset the voltaic balance was largest with the oxygen salts, intermediate with the haloid ones, and least with the free elementary halogens. It was smaller the greater the degree of chemical energy of the substance; thus it was about 400 times less with chlorine than with iodine. And it was smaller the greater the degree of freedom to exert that energy: thus it was about 5,416,000 times less with free chlorine than with potassic chlorate, or 1,570,000 times less than with the combined chlorine of the chlorate, and about 185 times smaller than with potassic chloride, or 88 times less than with the combined chlorine of that salt.

The order or curve of variation of potential by uniform increase of strength of the solution was different with each substance, and was apparently characteristic of the body in each case. A great number of such representative curves might be obtained with a zinc-platinum or other voltaic couple in different electrolytes.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Board of Electrical Control following up "Dead Wires."—The Attorney-General Declines to take Special Action against the U. S. Illuminating Co.—Execution by Electricity.—$10,000 a Year for Gas at the Brooklyn Jail; Electricity Recommended by Supervisor Quintard.—Rumors about Western Union.—The National Electric Light Association.—The Pacific Postal Telegraph Cable Co.—A New Board of Directors.—Mr. Levi P. Morton retires.

THE board of electrical control has addressed to the board of aldermen and the commissioners of public works a letter, based on the recommendation of a coroner's jury, in which the necessity for prompt action in the matter of enforcing the rules and regulations adopted by the subway commissioners is forcibly urged. The crying and imperative need for protection from the danger to life and limb with which the public are now threatened from dead poles and wires, and poles and wires which have never received the proper sanction of the authorities, is duly set forth, as is also the advantage to be gained by summary action on the aldermen's part. Following on this are signs of vigor that look as if the authorities had at last got down to business. Inspector McGuinness, with a dozen able-bodied men well supplied with ropes, picks and saws, and supplemented by a couple of wagons, began work on North William street on the 21st. inst., and soon had a number of the "dead" poles on their way to the corporation yard. Twenty-six poles along North William, Houston and Sixth streets were removed, and the work is to go on.

Attorney-general Tabor has denied the application of commissioner Gibbens, of the board of electrical control, to have him bring special action against the United States Illuminating Co., for failing to comply with the provisions of chapter 716, laws of New York, relating to electrical conductors. The attorney-general holds that the law provides a remedy.

At the inquest on a young man who was killed in a Bowery clothing store through touching an arc lamp, the jury's verdict censured the United States Illuminating Co., for having the lamps in a position that makes them dangerous to the public, and for not having their lamps and wires insulated. It also recommends that a corporation ordinance be passed compelling all electric light companies to insulate their lamps and wires, and also to insert a clause in their contracts with patrons, warning them not to touch the lamps or wires.

In view of the fact that in about four months the new law on execution by electricity goes into operation, any additional light on the subject of the nature and effect of electric currents has considerable interest. Mr. Harold P. Brown's experiments on dogs at Columbia College, while demonstrating very clearly the inadvisability of allowing the electric current to be used without due protection to the public, have also shown that as a means of taking life it may sometimes be effective. Regarding the possibility of mutilation, which is a matter upon which the adoption of electricity for executions may eventually depend, we have not yet sufficient data on which to form an opinion. It is not unlikely that before long scientists may extend their investigations in this direction; indeed, considering its importance it is desirable that a series of experiments under official auspices should be carried out without delay.

Supervisor-at-large Quintard, of Kings County, has sent a communication to the board of supervisors, calling attention to the expense of supplying Raymond street jail in Brooklyn with gas. The gas bills for the jail amounted to $8000 in 1887, and this year will probably reach $10,000. The supervisor recommends the substitution of electricity for gas, the county to use its own plant.

We hear nothing more of the sensational rumors with which Wall street was rife in the early part of last month, concerning Mr. Gould's intended sale of the Western Union Co.; but the public is quite prepared for new developments in regard to telegraphic matters in this country.

The National Electric Light Association this week will bring together a large number of representative electricians, and from the list of expected contributors, the papers to be read will be of great importance and interest, and valuable discussion may be looked for.

At the annual meeting of the Pacific Postal Telegraph Cable Company's stockholders, held at No. 1 Broadway, Mr. Levi P. Morton, who has been a member of the board of directors for years, sent in his resignation, and the following board was chosen for the ensuing year: John W. Mackay, of California; William C. Van Horne, Charles R. Hosmer, and Sir George Stephens, of Montreal; Albert B. Chandler, Henry Rosener, Hector De Castro, Edward C. Platt, and George G. Ward, of this city. Officers were re-elected as follows: president, John W. Mackay; vice-president, Hector De Castro; secretary, John O. Stevens; treasurer, Edward C. Platt; general manager, Charles R. Hosmer.

.... The fellow who is out of a job doesn't like monopolies. If his job is that of running a monopoly, or profiting by it, he is better pleased with it.—*The Millstone.*

PHILADELPHIA.

The New Edison Station.—The Keystone Light and Power Co. —Appeal to the Courts against City Councils.

THE Edison Electric Light Co.'s building, now in course of erection on Sansom street above 9th, and of which a complete description was given in a previous letter, is rapidly nearing completion, and bids fair to bear favorable comparison with any building for electric lighting purposes, in the country.

The indiscriminate tearing up of the streets of the city for the purpose of laying electric light and telephone conduits, may receive a sudden check now that the Keystone Light & Power Co. has gone into court to compel the city councils to give it a hearing. After months of fruitless effort the Keystone company has been obliged to adopt this course, because councils have always turned a deaf ear to the petitions of the corporation for an extension of its privileges.

The Penn Electric Light Co., which has a practical monopoly of the streets of the city for electric lighting, has bitterly fought the Keystone company at every point, and has prevented it from getting its ordinance considered favorably by either the board of highway supervisors or councils.

In order to reveal the secret of the opposition against it the friends of the Keystone company in councils succeeded in having a special committee appointed to investigate the general subject, but nothing ever came of it. The action of the Keystone company is somewhat novel, inasmuch as it is generally supposed by councilmen that councils have control of the streets, and they are anxiously awaiting the action of the court.

The Penn company has control of all the desirable territory in the city, and it rents out these privileges to the Edison and other companies at an immense profit. The Edison company has to depend upon the legal position of the Penn company for its franchise, so that the settlement of the matter will be awaited with some anxiety by those most interested.

PHILADELPHIA, August 18, 1888.

BOSTON.

The Association of Edison Companies meet at Nantasket.—Output of Telephones.—American Bell Telephone Co.'s Earnings.—Reports of the New England and the Erie Telephone Companies.—Telephone Lines Disturbed by Street Railway Currents at Quincy, Mass.—Advantages of the Police Signal System.—Fire Alarm Boxes in the State House.—The Westinghouse Suit against the Sun Electric Co. for Infringing the Gaulard and Gibbs Patent Dismissed.—The Thomson-Houston Regulator Patent Sustained by Judge Colt.—The Malden Electric Light Station, Bangor, Me., to have a Street Railway at last, and it is to be an Electric Road.—Electric Street Railway Notes.—The West End Co.—Mr. Whitney fully convinced of the Superiority of Electric Traction.

THE association of Edison Electric Illuminating companies, comprising those in the United States and Canada, met at Hotel Nantasket on the 8th inst., in semi-annual session, John J. Beggs, of New York, presiding. The following-named officers were elected: president, John J. Beggs, of New York city; vice-president, C. P. Gilbert, of Detroit, Mich.; secretary, J. H. Vail, of New York city; treasurer, Wilson S. Howell, of New Brunswick, N. J.; executive committee, A. L. Smith, of Wisconsin, F. R. Upton, of Harrison, N. J., C. L. Edgar, of Boston, Thomas P. Merritt, of Reading, Pa., R. M. Jones, of Laconia, Wis. Improvements, present and prospective, in lighting and power, were discussed at some length, and the evening was devoted to the reading of a paper, illustrated by the stereopticon, on the subject of "Protecting Electric Light Circuits from Lightning," by W. J. Jenks, of New York city. The meeting was continued during the 9th.

The statement of the output of telephones by the American Bell company for the month ending July 20, is as follows:

July.	1888.	1887.	Increase.
Gross output	4,485	4,345	140
Instruments returned	2,010	3,196	*1,186
Net output	2,475	1,149	1,326
Dec. 21 to July 20—			
Gross output	34,046	33,008	1,038
Instruments returned	12,886	14,310	*1,424
Net output	21,160	18,698	2,462

*Decrease.

Bell telephone earnings for June are said to show an increase of 60 per cent. over June, 1887, while the gain for July is placed at over $100,000 in comparison with the same month last year. Earnings now are stated to be at the rate of 28 per cent. per annum on Bell stock.

The New England Telephone Co. has declared a quarterly dividend of 75 cents per share, payable August 15, to stock of July

31. The books will be closed from August 1 to 14, inclusive. The statement of operations for the quarter ended June 30, is :

	1888.	1887.	Increase.
Gross	$280,116	$251,782	$28,334
Expenses	189,791	178,588	11,203
Net	$90,324	$73,194	$31,139
Construction	23,249	....	23,249
Surplus	$67,075	$73,194	*$6,019
Since Jan. 1.			
Gross receipts	$546,444	$491,690	$54,754
Earnings	380,025	343,949	36,076
Net earnings	$166,319	$147,641	$18,678
Construction	26,519	3,555	22,969
Surplus	$139,800	$141,091	*$1,291

*Decrease.

The regular quarterly dividend of 1¾ per cent. has been declared by the Erie Telephone Co. The statement of the operations for the first quarter of the fiscal year is as follows :

QUARTER ENDED JUNE 30.

	1888.	1887.	Increase.
Gross earnings	$163,662	$146,419	$17,243
Expenses	104,569	97,906	6,663
Net earnings	$59,093	$48,513	$10,580
Construction	9,870	8,657	1,213
Surplus	$49,223	$39,856	$9,367

SUBSCRIBERS.

Added—	1888.	1887.	Increase.
Quarter	204	276	*72
Total connected—July 1	10,747	9,998	749

*Decrease.

Telephone subscribers at Quincy complain that it is almost impossible to use their instruments after nightfall when the electric street lights are turned on. The wires of the telephone company and of the electric light company are run for the most part upon the same poles, the result being that the heavy current on the light wire produces a loud buzzing noise on the telephone circuits.

Irrational persons are often heard to say that a police officer can never be found when wanted. At times, as is admitted by the superior officers of the police department, there appears to be ground for the statement. This will not be the case any longer, thanks to the police signal system by which an officer is compelled frequently to report by signal to the station while patrolling his route. There can be no shirking of duty—every patrolman being constantly under the thumb, so to speak, of the officer in charge of the station house.

The sergeant-at-arms has had placed in the State House seven alarm boxes, which are put in and connected with the city fire alarm telegraph by the Gamewell Auxiliary Fire Alarm Co. Every floor of the building is covered. The annual expense to the state is very small—less than $50.

Judge Colt, of the United States Circuit Court, has dismissed the plaintiffs' bill in the case of the Westinghouse Electric Co. *vs.* the Sun Electric Co., which was a suit brought to enjoin the defendants from infringing letters patent granted October 26, 1886, to George Westinghouse, Jr., assignee of Gaulard and Gibbs, for the method of electrical distribution by alternating currents and converters.

A decree for an injunction and an account has been given in the United States Circuit Court in the suit of the Thomson-Houston Electric Co. *vs.* Citizens' Electric Light Co. *et al.*, brought to recover damages for an alleged infringement of letters patent No. 238,315, granted to Elihu Thomson and Edwin J Houston, March 1, 1881, for improvements in current regulators for dynamo-electric machines. Defendants used the Fuller-Wood regulator, which was manufactured by the American Electric Manufacturing Co.

By invitation of the officers of the Malden Electric Light Co., a number of persons recently inspected the station which has been erected for the company on Centre street, Malden. The station occupies an excellent building, and is equipped with everything necessary to conduct the electric lighting business successfully. The company is now supplying 300 arc lights for the streets and stores of Malden, Melrose and Everett, and has capacity for supplying 300 more arc lights. It is also supplying for Malden, Melrose and Everett, 400 incandescent street lights, and has power to produce 400 more. J. S. Bartlett, of Lynn, is president of the company, and A. E. Bliss, of Malden, is superintendent.

The electric light company in Salem is supplying 250 arc lights and from 300 to 350 incandescent. The city has 145 electric street lights.

Something is going to happen in Bangor that will astonish the natives more than anything that has occurred since the electric lights first banished Egyptian darkness from its queer old streets, and when it does happen many of the older settlers are expected to take to the woods. For 54 years this has been a city, and yet in all that time, unless one had a stable of his own, there has been no way of getting about the streets except by walking or hiring a carriage for every trip. But now there is to be an electric street railway. The enterprise has been opposed and hindered in every way. Some didn't want the looks of certain streets spoiled by the erection of poles and wires, and others objected to tracks being laid in certain streets because it might injure those thoroughfares as driving courses. But the company has finally got the right of way, and the road is now being built.

The new electric motor on the Willows branch of the Naumkeag Street Railway at Salem was tested July 21, a car being run from Webb street to the Willows and return. The car ran easily. The line to Washington street will be completed this week. The rumor that an injunction had been placed on the running of the electric cars by the Boston & Maine Railroad, on account of the wires passing over the Maine railroad tracks in reach of men on the top of cars, is authoritatively denied.

The new electric railroad at Meriden, Conn., run by the Daft overhead system, has been tried several times and has been very satisfactory. One or two slight "hitches" have been experienced, but these are now remedied and will not be repeated. The line will be formally opened shortly and running on a regular schedule of time.

At a meeting of the Boston aldermen, July 30, a petition from the West End Railway was presented, asking for the right to establish and maintain the electric system of motive power in the operation of its cars, and to erect and maintain poles and wires for the overhead system in some streets, and for leave to establish, maintain and use the conduit system in certain other streets, and to make the necessary underground and surface alterations therefor. The same company petitioned for a location on Harvard bridge and West Chester park, and that a part of the bridge be set apart for the use of street cars. Both petitions were referred to the committee on railroads.

A large party headed by president Whitney and the directors of the West End Railway, joined in experiments with the Thomson-Houston system of electric cars at Crescent Beach and inspected the works of the company at West Lynn, July 30. On the arrival at the beach the electric motor car, which for some weeks past has been running on Atlantic avenue, was found attached to two ordinary street cars. It was learned that the weight of the motor car was 9,500 pounds when empty, and when occupied by 47 passengers was 17,000 pounds; 8½ h. p. being required to remove it 12 miles an hour. The weight of the three cars was 19,500 pounds, and with the 79 passengers, 32,000 pounds. Propelled from an overhead wire, the train moved toward the Atlantic House at a moderate rate of speed, stopping at intervals to test the apparatus for checking motion. By this system the difficulty is avoided of having to adjust the armature bearings at each trip. Another gain is in the use of only one commutator for each motor. There are also self-oiling bearings, the armature turning in an oil cup. In the overhead connection the insulators surpass others in the completeness with which they save dynamic leakage. When the first trip and return had been made with three cars, two trips were taken with the motor car alone, to permit the party to note the speed which could be safely attained. On the first passage over the track, which is 4,870 feet in length, the rate of speed ranged from 12 to a little more than 13½ miles an hour, and on the second trip it reached a speed of upward of 15½ miles. Among other excellencies incidentally discovered during the trip were the mechanical arrangements which prevented the sparking of the track and armature, and the valuable lightning arresters, designed to prevent the burning out, which has been known to occur at Rochester and some other places. After an hour in the dining hall of the Strathmore Hotel, the party, by invitation of the officials of the Thomson-Houston company, visited the works. The last of 61 new open cars will be put into service next week. The Newburyport Car Manufacturing Co. is building 20 box cars for the Beacon street electric line. Colonel Bancroft, the roadmaster of the company, is constructing the tracks on Beacon street, westerly from Harvard street, as fast as possible. The line to Chestnut Hill will in all probability be completed in four or five weeks. The Sprague Electric Railway & Motor Co. has already begun to prepare the equipment for the cars which will run on Beacon street, Brookline. President Whitney expects to have the road in operation by October 1.

The selectmen of Brookline gave a hearing on the 16th ult., upon the petition of the West End Street Railway Co. for leave to erect and use an electric system of motive power in the operation of its cars in the town. President Whitney said that two or three months ago officials of the company visited Brooklyn, N. Y., and were so well satisfied with the working of the overhead conductor system there that they stopped work in Boston on the cable system. President Whitney and other officials then visited Richmond. There they found an overhead wire system in operation, comprising about 12 miles of road in which there were curves such as do not exist in the many miles included in the West End system. The system there had given entire satisfaction, and it was probable that before October next 75 or 100 cars would be running in that city. Alleghany was also visited. There the same system was in operation, and the cars were propelled over grades not exceeded in the vicinity of Boston, excepting Summit avenue on Corey Hill. The company's officers who examined these roads were convinced of the practicability of the motor employed. There was still opportunity for great improvement, Mr. Whitney said, but the use of electricity had reached a stage of development which warrants its adoption in the place of

horses. The company purposes to use a cable in the city and an overhead system in the suburbs. On Beacon street the plan is to suspend the cable carrying the electric current from cross wires attached to gas pipe posts set upon either side of the track about 22 feet apart. The space between the trees where the tracks are located will be grassed over, adding materially to the beauty of the street. If the petition of the company is granted, Mr. Whitney said the system will be in operation early in September, if not on the 1st of that month.

In response to inquiries, Mr. Whitney said the limit of speed on the road would only be determined by the question of safety. He had ridden at the rate of 15 miles an hour or over on the roads which he had examined. It would be possible on Beacon street to make 15, or even 20, miles an hour.

Mr. Dana Estes spoke warmly in favor of granting the petition. There was no opposition expressed in regard to the introduction of the system on Beacon street, but several speakers object to its use on Longwood avenue, which is a narrower thoroughfare. The selectmen took the matter under consideration.

BOSTON, August 16, 1888.

CHICAGO.

Annual Gatherings of the Military Telegraph Corps and Old Time Telegraphers; Address of President Plum; Election of Officers.—Embarrassment of Telephone Service by the City Ordinance of last January.—The Cushman Telephone want a Re-hearing by Judge Blodgett.—The Ordinance Limiting Telephone Charges.—A Chicago Physician Criticises the Telephone Service.—Chicago Electric Club Notes.—The Storm of August 2.—The Sperry Electric Company.—The Western Electric Company to Furnish the Electric Lighting for the Exposition.—Success of the City Lighting Plant.—A New Motor by Mr. Sperry.—The Illinois Phonograph Co.—Suits against Shareholders of the Great Western Telegraph Co.—Electric Light Notes.—New Incorporations.

THE United States military telegraph corps and the Old Time Telegraphers' Association held their annual sessions in Chicago, August 15–16. The two organizations are practically one. The object of the annual reunions is mainly social; but for some time the military corps has been endeavoring to secure from Congress, some recognition of its services during the rebellion. In his annual address the president W. R. Plum, of Chicago, spoke of the important aid which the telegraphers had given the Union cause. Notwithstanding this the service had been unrecognized, he said, and not an operator of the corps had ever received a pension, an acre of land, a bounty, or even thanks. Only the officers who were commissioned to command the corps had been honored. The address contained many extracts from reports in which the zeal and faithful unobtrusive service of the operators were commended by commanders. A resolution of sympathy on the death of the general of the army was ordered sent to Mrs. Sheridan. The following officers were elected :—

President, W. R. Plum, Chicago; vice-president, George C. Maynard, Washington, D. C.; secretary and treasurer, James E. Pettit, Chicago.

The Old Time Telegraphers' Association held its annual session August 16th. The society includes in its membership all those who handled telegraph instruments during the first 25 years of the history of the telegraph. The association has for its object the collection and preservation of all records relating to the early days of the telegraph. The following officers were elected :

President, Charles E. Taylor, Frankfort, Ky.; vice-president, Day K. Smith, Kansas City, Mo.; secretary and treasurer, W. J. Dealy, N. Y.; executive committee, R. J. Hutchinson, N. Y.; S. B. Fairchild, St. Louis; J. M. Turner, New Orleans; Uriah B. Wilson, Denver, and the officers *ex officio*. It was voted to hold the next reunion on the first Wednesday and Thursday of September, 1889.

At the close of the session, the members of the two organizations joined in an excursion on the lake. In the evening a banquet was given at which there was a large attendance. The occasion was of a particularly pleasant character. The members who are full of reminiscences enjoyed the opportunity of comparing notes and living over the days which were passed on the battlefield. The following toasts were responded to :—

"Professor Morse, the inventor of the telegraph. God gave him to us, and after he fulfilled his mission God has taken him away," J. D. Reid, New York. "The Army Telegrapher, first in war, first in peace and last in the hearts of his countrymen," A. H. Bliss, of Chicago. "The Boys," N. L. Ives, of New York. Colonel R. C. Clowry, of Chicago, made a brief speech. The banquet closed with the singing of "Auld Lang Syne."

There is a great deal of fault found at present with the ordinance which prevents the Chicago Telephone Co. from extending its lines. The ordinance was adopted in January last, and provided that the commissioner of public works should issue no more permits to the telephone company until directed by action of the city council. There are now said to be over 210 persons who have made applications for instruments but are unable to secure them on account of this piece of local legislation. Physicians who have recently moved to the city and storekeepers who have recently established their business seem to be the greatest sufferers. They feel that competitors who have telephones have a great advantage over them, and they complain bitterly. The company has not fought the ordinance, because it is said its officers did not desire to increase the business while moving into the new building. Superintendent Wilson said on this subject: "We could soon supply all applicants if the prohibitory order were repealed In the outlying districts it might take some time, but we could put in a thousand instruments in a few months. We have made plans to give Chicago the most perfect telephone service in the world, but we can do nothing more until we can extend our underground system. We are putting in some telephones on private property, but that is all."

Professor J. P. Barrett, city electrician, said he thought the prohibitory order extremely bad policy, and resulted in more harm to the city than to the company. "I have," he said "at times 50 callers a day who make complaints about the order. They cannot see any sense in the order and neither can I. It should be abolished at once."

Assistant corporation counsel Knight, who is the legal adviser of the Cushman Telephone Co., of Chicago, recently said in reference to the adverse decision of Judge Blodgett, "The Cushman people will endeavor to get a re-hearing before Judge Blodgett, and if this is granted and additional evidence is submitted the decision may be reversed, so we can get our instruments and go ahead with the exchange in Chicago. The company is ready to establish exchanges as soon as legal matters can be settled."

The ordinance which reduces the charges of the Chicago Telephone Co. will come before the council again in September. Its franchise may be called in question if a fight ensues. It has been asserted that the Cushman franchise might become valuable as the only one which would permit of the use of wires for telephones in case the Chicago company should be defeated. The Cushman officials declare they would not dispose of their franchise under any circumstances, and the Chicago company officers insist that they would not buy it even as a last resort.

Some comment has been caused by an open letter addressed by Dr. E. M. Hale, a prominent Chicago physician, to the Chicago Telephone Co. It was a stinging criticism of the service. He ridiculed very sarcastically and at considerable length the practice of attributing every fault in the system to induction. He found that the company was guilty of many and weighty sins of omission and commission.

The Chicago Electric Club has voted to discontinue literary meetings until the first session in October. At a recent meeting of the officers and managers the following committee was appointed to consider the question of securing new quarters for the club: S. A. Barton, C. A. Brown, B. E. Sunny, C. D. Shain and H. Ward Leonard.

The present rooms, while pleasant and comfortable, are not as elegant as many members would like to see. The cuisine especially has been the cause of considerable fault finding. At a meeting of this committee, H. Ward Leonard and B. E. Sunny were appointed a sub-committee to visit and report on rooms adjacent to the University Club.

President Barton, of the Electric Club, has brought up the question of organizing an electric exchange similar to the New England Exchange of Boston. The matter has been informally discussed by the officers and managers, and the following committee has been appointed to consider the matter: B. E. Sunny, C. A. Brown, C. D. Shain, J. P. Barrett and F. W. Horne.

The storm of August 2d was unusually severe in Chicago. Lightning struck in eleven places. The stables belonging to the Union Stock Yards and Transit Co. were struck, and a loss of $15,000 was occasioned. The fire alarm system of the town of Lake was rendered useless. Lightning affected the instruments in the telephone and telegraph offices, but beyond frightening the employés did no harm.

Most of the stock of the Sperry Electric Co. has been placed, and an organization has been effected by the election of the following officers: president, Samuel P. Parmly; vice-president, D. P. Perry; secretary, George H. Bliss; treasurer, E. E. Crepin; electrician, E. A. Sperry. The capital stock is $250,000.

The electric motor has recently been employed to excellent advantage for running fans in the sick room, in Chicago. A complete fan outfit run by two cells of storage battery has kept comfortable an apartment in which a Chicago capitalist has been confined by a broken leg.

The Western Electric Co. will furnish 200 arc lights for illuminating the Chicago exposition building this fall. A considerable number of incandescent lamps will be installed, and current will be supplied for several Baxter motors.

A Chicago amateur detective recently made as he thought an important discovery which threw light on a tragedy. Mr. and Mrs. Heesch were found dead in their home. The man had beyond doubt committed suicide, but the woman's death formed a mystery. The amateur detective found an electric battery in the house, and formed the theory that the husband while assisting his

wife to take an electric shock had administered a fatal charge, and in his despair had taken his own life. An electrician who was consulted, upset the theory by saying that two dollar batteries are not sufficiently powerful, ordinarily, to cause death.

It is asserted that the city electric plant besides affording improved illumination, will prove an economical venture for the municipality. Figures show that the cost of maintaining each electric light will be $15 per year, while the cost for the gas lamps has ranged from $20 to $30.

Elmer A. Sperry has invented a double induction motor, for which great excellence is claimed. The inventor asserts that its construction is such that its efficiency is high, and that the unsatisfactory working which usually characterizes small motors is entirely overcome. The motor can be operated from a battery or from an arc or incandescent circuit.

The Illinois Phonograph Co. has been incorporated, with headquarters in Chicago. The capital stock is $1,250,000. The incorporators are Frank A. Wunder, William L. Abbott, and Henry P. Barton. Harmon Spruance, formerly of New York city, has purchased the right to rent instruments in Illinois, and is at the head of the movement in Chicago.

United States senator Charles B. Farwell, of Chicago, has been sued for 1,500 by Elias R. Bowen, receiver of the Great Western Telegraph Co. Senator Farwell was one of the original subscribers to the capital stock of the company, and there is $1,500 yet due and unpaid on his stock. Mr. Farwell is only one of several hundred stockholders who are being proceeded against for the benefit of the company's creditors.

The capital stock of the Consumers' Electric Light Co., of Chicago, has been increased from $100,000 to $200,000.

The Normal Electric Light Co., of Normal, Ill., has been incorporated with $5,000 capital stock. The incorporators are M. T. Burrell, C. L. Gilt, H. C. De Motte, O. Seibert, and Charles De Garmo.

An electric light plant is to be installed in the Chicago North Side Waterworks, for the illumination of the shore inlet and the water works.

The South Side Electric Light & Power Co. has been incorporated with $50,000 capital stock. Those interested in the company are H. V. Harris, James Hood and Frank Butterworth.

The Electric Date and Time Stamp Co., of East St. Louis, has been incorporated. The capital stock is $1,000,000, and the incorporators are William H. Stevenson, James B. Johnson, J. M. Thompson and Hamilton Doughorday.

The Citizens' Electric Light Co., of Collinsville, Ill., has been incorporated; capital stock $100,000; incorporators, S. W. Baird, A. P. Baird and M. T. Baird.

The electric lighting plant at the stock yards has been completed. The cost was $12,000. Considerable of the stock received at the yards is unloaded at night, and the danger in unloading is great. There is also a good deal of switching and shipping done. No part of the yards is now in darkness. There are 70 lights supplied by two dynamos. Fifty-one are in use at present. The lights are brilliant, steady and economical. They extend from Winter street to Ashland avenue along 40th street. There is a cluster of lights upon a tower in that part of the yards where most of the work is done. The tower is 120 feet from the ground, and may be seen at a great distance.

CHICAGO, August 21, 1888.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall street, New York city.*

WELDING RAILS BY ELECTRICITY.

[97.]—I find it necessary to respond again to Mr. Otis K. Stuart's attack on my method of welding rails by electricity, which he renews in your August number.

It appears that Mr. Stuart is not yet entirely satisfied that he is in the wrong, and after very conveniently waiving all further discussion of the points first brought up by him, he now grasps at one or two remaining straws in a vain attempt to prove that the welded joints of the "continuous" rail sections cannot be retempered. He then proceeds, under the flattering assumption that I know nothing about welding, to discourse to the reader at length upon the results of his own experience with welding currents, and endeavors to explain the *modus operandi*, according to his conception of what takes place, in a direction that is entirely foreign to the questions at issue between us.

Mr. Stuart starts out by stating that his previous letter was *not* a criticism of my method of welding and laying railway tracks, but was prompted by the general statement or notice originally published by you. Yet, a little further on, he admits that he was acquainted with my patent when he wrote his first letter, and confesses that he was *then* and is still unable to find therein any method of restoring the temper. It is very easy not to find a thing when one doesn't wish to find it, but nevertheless the method of re-hardening or re-tempering the welded joints is operatively described in a manner sufficiently clear to enable anyone skilled in the art of electric welding to practice it, as may be readily seen by referring to the patent itself, No. 370,282.

Aside from all this, however, I am prepared to maintain, notwithstanding anything Mr. Stuart has said to the contrary, that with the proper arrangement of welding clamps and apparatus, and re-hardening and tempering means, such as I propose to employ, the welded rail joints can be restored to their normal degree of hardness *without leaving an annealed portion on either side*, and it appears to me to be futile for Mr. Stuart to indulge in prophesies of failure until after he has something more tangible to base them upon than theories derived from the state of his present knowledge.

Mr. Stuart, however, not satisfied with denying the practicability of what I still persist in terming "my method of electrically welding and tempering," goes further than this, and, presumably referring to claim 2 of my patent, in which is set forth the feature of gradually increasing the current strength, states positively that no greater piece of electrical nonsense has ever been written. We shall see. It is a fact well known to every blacksmith or tool maker that good steel will not bear a white heat in the open air without being "burned," and that even at a bright red heat it will crumble under the hammer. Is not Mr. Stuart's position, therefore, utterly absurd when he states, in this connection, that in dozens of foundries in this country steel is melted and poured into moulds, with no gradual increase of the current to prevent burning?" Does Mr. Stuart mean to imply that because steel can be cast without destroying its tempering properties, that he can therefore subject a bar of steel, clamped in his welding machine, to any degree of heat with impunity, and without burning it or injuring its tempering qualities?

Mr. Stuart further states that he has frequently welded steel without injuring its tempering qualities, by gradually *reducing* the flow of current. What does this prove in this connection? Nothing. Anyone familiar with electric welding knows that a weld can be effected with a constantly diminishing current strength, if the precaution is taken to have the ends of the pieces in good, square contact at the beginning of the operation. In this case the resistance opposed by the joint is comparatively small at first, permitting a large initial flow of current that is automatically reduced as the metal becomes heated, and increases in resistance by virtue of this heat. This method of operation is not generally followed in practice, as Mr. Stuart fully knows, for in order to localize the heat more thoroughly, it is usually necessary to reduce the cross-section at the ends of the pieces to be joined, this latter method also producing a more perfect joint, by reason of the more intimate union of the metals that occurs when the pieces are forced together. In this method of operation the resistance of the joint is usually *greatest at the commencement of the welding operation*, and *diminishes* as the metals are forced together and the joint approximates its full diameter. It will be seen therefore that even without the aid of exterior regulation to assist this action, the current in this case, with a constant potential in the welding circuit, *is of necessity a gradually increasing one*, and I have no hesitation whatever in saying that most of the work done by the machines of the Thomson Electric Welding Co., whether by Mr. Stuart or anyone else, *is a direct infringement of the second claim of my patent*, quoted in my previous letter in the July number of the ELECTRICAL ENGINEER. Is it any wonder that Mr. Stuart is so anxious to have the public believe his assertion, "that a greater piece of electrical nonsense has never been written than the statement made in claim 2?"

One more point, and I am through. Mr. Stuart evidently confuses a gradual heating effect with a gradual increase of current strength. These are entirely distinct, and in one sense absolutely independent of each other. It is the gradual increase of *current* that forms the subject of the claims under notice, and *not* the gradual increase of the heating effect. This latter is mainly a function of, and depends upon, the heat conductivity of the metals, and it is because of the comparative slowness of this action and the consequent liability of overheating that portion of the joint first acted upon by the current, that the necessity arises for "gradually increasing" the current strength. It will be readily seen that in the welding of large pieces, such as steel rails, if the full welding current is suddenly passed between the tapered ends of the rails there is decided danger of abruptly raising these abutting portions to a white or "burning" heat before the fusing action of the current and the heat convection combined has appreciably affected or heated to redness the ends of the rails proper. The automatic variation in the resistance of the joint, before referred to, cannot always be *alone* relied upon to permit of the desired flow of current, and in the welding of steel, or in fact *any* metal the structure of which is such as to become injured by overheating, I employ a suitable reaction coil or other regulat-

ing device by means of which the initial current can be adjusted to suit the *area of contact* at the ends of the pieces about to be united, and by which the current can be gradually increased as the ends of the metals unite and the increasing cross-section at the joint demands a heavier current.

Of course, Mr. Stuart is at liberty to weld as often as he pleases by *reducing* the current, and as $H = C^2 \times R \times T$, he can within certain limits, go a step further, and devote all the time he likes to the operation by using a still smaller current. For my part, I find that *increasing* the current strength, as described and claimed for the first time in my before mentioned patent, fills the bill to perfection, and at the same time permits of more perfect, rapid and economical work, not only in the case of steel, but in other metals.

Thus far I have been unable to see a single point in my system that has been met or weakened by anything Mr. Stuart has said, and if, as requested in my previous letter, Mr. Stuart will wait until he sees a practical railway line having continuous rail sections in successful operation, he will I trust, like a good many other doubting Thomases who flourished before him, eventually see things in their proper light. ELIAS E. RIES.

430 S. Broadway, Baltimore, Md.

GLASS HOUSES AND STONE THROWING.

[98.]—In reading your remarks in your last number about a contemporary who had lectured the fraternity of technical journals for cribbing from its columns without acknowledgment, and noting particularly your quotation against him of the old adage "People who live in glass houses should not throw stones," in an expanded and odious metrical paraphrase, due, I suppose, to some scribbler emulous of the Great Tupper's fame; it occurred to me that you must have failed to read with due attentiveness Mr. Rice's monthly magazine (issued under the sometime-honored title, *The North American Review*) for March last. In that number, among the writers relegated to fine print on the back pages, Mr. Walter Gregory very cleverly and successfully demonstrates the absurdity of the adage about stone throwing from glass houses. He says the occupants of glass houses "are the only ones who may" throw stones, and his ground is that it is only those addicted to particular sins and vices who can speak understandingly about such sins and vices; as to the good and virtuous, "their very immunity and perfection disqualifies them." Mr. Gregory further says, "The new doctrine is the one to which we must come. * * * When it prevails we shall all be wiser and happier than in these days when we are 'censors of such vices as we are not tempted to commit, and satirists of such virtues as we are not allured to imitate.'"

May not your esteemed contemporary have simply put in practice this new and better teaching? F. J. R. C.

LITERATURE.

REVIEWS.

Betrieb der Galvanoplastick mit Dynamo-Electrischen Maschinen zu Zwecken der graphischen Künste. Von OTTOMAR VOLKMER. Wien, Pest, Leipzig. A. Hartleben's Verlag.

THIS little volume of the *Chemisch-technische Bibliothek* presents in a clear and comprehensive way the principles and the essential details of various forms of electroplating and electrotyping. The book is a model of definiteness and conciseness. The amount of information is unexpectedly great. Systematic arrangement and the omission of unessentials contribute largely to the author's success. His descriptions and conclusions are for the most part based upon the instruments and experiments in the royal "Militär-geographische Institut" and the "Hof-und Staatsdruckerei" at Vienna, and include many recent and interesting processes of reproduction of figures by the electric current. The statistics of the current and amount of metal deposited, collected and collated by the author, are comprehensive and very useful for reference. It is a pleasure to find a German scientific writer who takes some pains with his style of presentation. Herr Volkmer, with some other recent German scientific authors, apparently respects the time and patience of his readers and recognizes the duty of an author to be perspicuous.

The discussion, in the first chapter, of the dynamos used for plating is wisely confined to the Gramme, Schuckert and Krötlinger machines, "because in Germany and Austria these systems have enjoyed greater favor." By reason of this concentration it is possible to give full and accurate data. The author avails himself of this, and gives a thoroughly satisfactory account of the construction of the machines, the power necessary to run them, and the work that can be got from them. The few pages he devotes to the statement of the fundamental principles of the dynamo and the description of ammeter, voltmeter and gas engine are quite admissible, as being not out of place in a popular development of the subject.

Chapter Two, which sets forth the laws of electrolysis, contains, besides the laws of Faraday, the results of several experiments. The most important are those of Baron Hübl (of the Militär-geographische Institut), which determine the physical peculiarities of electrically deposited copper and the conditions for the production of a good plate. The general laws of Smee and others on the relations between the strength of current and the nature of the deposited copper, are well supplemented by the definite results of Hübl. The table showing the relation between the composition of the bath and the maximum useful current per sq. dm., is particularly good. Hübl's determinations of the absolute rigidity, the limits of elasticity and hardness of the metal under different conditions, are of significance and importance to the specialist. The sections on the arrangement of the bath and plates are interesting, as showing the method employed at Vienna. The cautions of the last part of the chapter are worthy of some attention by those not already informed.

In the fourth chapter is found the main substance of the book. Brief but accurate accounts are given of the preparation of the ordinary plate, and that faced with steel, nickel or brass, as well as of the most important methods of photo-mechanical reproduction. The author, without sacrificing technical accuracy, has succeeded in putting his work in popular form. Of the eighteen processes described it will be possible to mention only a few of the most interesting. Not least important is the steel facing of a copper plate. Four or five minutes suffice to deposit a layer of steel, which will give from 6,000 to 12,000 impressions without renewal; after which, renewal is quite as easy as the original process. To this process and to the heliogravüre, considerable space is rightly devoted. The novel feature of the chapter is the description of electrotyping flowers and insects from nature.

The author, through his position under the government has had excellent opportunities for observation, and it is a satisfaction to find him so definite in his statements. The reader is left in no doubt as to the composition of the solutions, or the amount of current necessary for a given result. He is even admitted to a view of the machinery. It is just in this particular of definiteness that the value to the specialist of this part of the book lies.

The plan of the book is adhered to in the last chapter—on chemicals. The main facts regarding the substances employed are briefly stated for general information. Yet it is not alone the general reader that can profit by the succinct record; though even with the tables of density in the appendix, its use as a reference book is necessarily very limited. On the whole, this exposition of the processes (as they exist in Germany) of electro-metallurgy for purposes of graphic art is quite timely. That many of the methods are already well known is no reason why they should not be published in logically complete form, and an interesting, not to say valuable, description given to the world.

Principles of Dynamo-Electric Machines. By CARL HERING. New York: W. J. Johnston, 1888.

MANY readers of THE ELECTRICIAN AND ELECTRICAL ENGINEER will remember the admirable serial article on the construction of dynamos, by Carl Hering, which ran through the fifth and sixth volumes of this journal, and will recall with pleasure his original method of treating the subject, as well as the simplicity and clearness of his style. The republication of this serial in the shape of a handy little volume, with such revisions and additions as the author has thought to be desirable, will be sure to meet with the approbation of those who were fortunate enough to be familiar with it in its original form, while to many who were not so favored it will come as a most acceptable manual.

Mr. Hering's practical familiarity with the various types of modern dynamos has enabled him to treat of the details of their construction in a manner which few writers have attempted, and he has consistently confined himself to that practical treatment of the subject which it was his stated intention to pursue. The design of the book is to give in a concise and simple form the information most required by those using, building or repairing dynamos, and it is little to say that this object has been successfully accomplished.

The general plan of the author has been to take as a basis for his reasoning, or as models, those modern dynamos which have proved in practice to be the most efficient converters of energy, and from their actual dimensions deduce the best proportions for the various elements in dynamo construction, and the theoretical reasons why such designs must be, on general principles, the most effective. His method is strictly analytical and the practical illustrations which are always given are followed in a logical manner by all essential explanations of the underlying theory.

For the benefit of such readers as may not have the necessary knowledge of the fundamental laws of electricity, and of the units and terms commonly employed in dealing with electrical phenomena, the first chapter has been devoted to their explanation. Potential, current and resistance, and their relation to force and work, are clearly and ably defined, as well as most of the electrical phenomena with which the book is concerned. The reference in this chapter to the earth as a reservoir of electricity of infinite quantity, is not scientifically accurate, however, and seems to be unnecessary as well as misleading. In discussing the

fundamental principles of dynamos and motors in the next chapter, it is shown that complicated theories as to their action are unnecessary, and in illustration, some simple and instructive experiments are described. This is followed by a clear and comprehensive explanation of the theory of magnetism and electromagnetic induction, which cannot fail later on to aid the student in understanding the principles upon which the action of dynamos depends. The laws governing the generation of electromotive force in such machines are next considered, and this force, which is the fundamental element with which we have to deal, is shown to be dependent on the length and velocity of the moving conductor and on the intensity of the magnetic field traversed by it, in a way that can be readily comprehended by those having but little familiarity with the subject.

After this preliminary and very useful explanation of principles, the author passes directly to the practical construction of dynamos. The various types of armatures are described in detail, and their differences and advantages for particular work pointed out. Practical methods of designing and winding armatures to accomplish predetermined results, are explained with sufficient fulness to enable any ordinarily intelligent person to apply them successfully. The various forms given to field magnet frames are carefully considered and their effectiveness criticised, and rules for winding such frames with series or shunt coils, are laid down in great detail. In all of this portion of the work the author's actual experience in manufacturing machines is made apparent. No details are thought too insignificant to receive attention, and it is this completeness that will make the volume particularly valuable to the dynamo builder. Methods of regulating dynamos and of testing machines during and after construction are fully set forth in the concluding chapters, and indeed it may be said that nothing relating to a dynamo-electric machine from its conception to its completion has been omitted.

The volume is concluded with much valuable matter in the form of five appendices. The first of these deserves more than passing mention, and will repay a careful perusal by all who are interested in well proportioned dynamos. It is nothing more than a skillful tabulation of the various mechanical dimensions and electrical quantities of the seven dynamos tested in 1884 by the Franklin Institute committee, and it shows in a convenient manner how the various mechanical proportions of these machines have affected their electrical output. The conclusions which may be drawn from these comparisons are admirably discussed in the accompanying text. The so-called dead wire in Gramme armatures, and certain explorations of the magnetic fields surrounding well-known types of dynamos receive attention in two other appendices, while the fourth describes several methods of winding drum armatures. The fifth appendix is Mr. Hering's well-known table of equivalents of units of measurement, with several useful additions.

Electrical artisans and students, and those engaged in manufacturing and handling dynamos, will find this volume to meet an acknowledged want, and to such it may be commended with confidence.

On Some Possible Methods for the Preparation of Gramophone and Telephone Records. By Professor Edwin J. Houston. Read before the American Philosophical Society, April 20, 1888. Paper, 8vo. 4 pp.

CATALOGUES AND PAMPHLETS RECEIVED.

The "C. & C." Electric Motor Co. continue to issue tasteful and elegantly illustrated circulars setting forth successful applications of their motors. Their last pamphlet exhibits, along with several other uses, the adaptation of their motor to the propulsion of small boats or launches. An application which should prove very acceptable to people who have had to sit near a hot and hissing steam boiler in a small pleasure boat.

The New Haven Clock Co. some years ago, in reaching out for new fields, dashed in among the manufacturers of electrical apparatus, and have now become prominent competitors of old established electrical manufacturing concerns. Their recent catalogue represents a very full line of electrical apparatus, being specially full in telegraphic and other signaling machinery and supplies.

I. W. Colburn & Co.'s (Fitchburg, Mass.) price list and hand-book of dynamos and electric lighting apparatus and supplies, is a very dainty little book—small enough for a watch-pocket—and contains much useful and interesting matter. As was the case with Mr. Samuel Weller, our "wision is limited," and we have not been able to get the full benefit of the pages printed in microscopic type.

Mr. M. Richards Muckle, Jr., of Philadelphia, inventor of an underground conduit system for electric wires, has done well to include in his pamphlet describing his system the full text and drawings of his several United States patents thereon. Circulars of this character are too frequently—almost always—devoid of detailed information of the devices or schemes set forth, and are chiefly filled with more or less extravagant claims of a general kind, to supreme excellence. Mr. Muckle is of the firm of M. R. Muckle, Jr. & Co., engineers, Philadelphia.

The Daft Electric Light Co., now removed and established in its commodious factory at Marion, N. J., has isssued a handsome cloth bound quarto of 38 pages under the title—Distributory Electrical Power Plants, Daft System. In addition to illustrated descriptions of the Daft dynamos and motors, the book contains a considerable number of reports by people who have used the Daft motors. The descriptive portion ends with the following frank expression:—"It should not be overlooked that the foregoing description of Daft electrical power plants only applies to their status at the time of writing, and that a very brief interval may render it comparatively obsolete." All others engaged in electrical motor enterprises might truthfully say the same.

The Gibson Electric Co. recently issued a pamphlet circular setting forth the merits of the Gibson storage battery. Mr. Gibson, like many other inventors who have taken up the accumulator problem, has devoted his attention chiefly to devising methods of construction that would prevent rapid distortion and disintegration of the battery plates, and very remarkable results in that direction are claimed for his accumulators in the pamphlet under notice. The office of the company is at 775 Greenwich street, New York city.

NEWS AND NOTES.

DECISIONS IN PATENT SUITS.

THE THOMSON-HOUSTON REGULATOR PATENT SUSTAINED.

Circuit Court of the United States, District of Massachusetts.

IN EQUITY.

THOMSON-HOUSTON ELECTRIC CO., v. CITIZENS' ELECTRIC LIGHT CO., ET AL.

OPINION OF THE COURT.

[August 14, 1888.]

COLT, *J.* This suit is brought for the infringement of letters patent No. 238,315, granted Elihu Thomson and Edwin J. Houston, March 1, 1881, for improvements in current regulators for dynamo-electric machines. The specification says:—

"The object of our invention is to provide improved means for controlling automatically the strength of an electric current flowing over a circuit composed of a dynamo-electric machine and one or more electric lamps, or other appliances, through which the current passes, and to obtain said control without the introduction of resistances as such, and without varying the speed or field of the dynamo-electric machine, and at the same time, if desired, to utilize the reaction principle for the magnetization of said dynamo-electric machine, or in other words, to cause the current generated to pass through the field-magnet coils. We accomplish these results at the same time that the power expended to drive the dynamo-electric machine varies directly in accordance with the changed resistance of its circuit, being less as the resistance is less, and greater as the resistance is greater. * * * In the improved system of operation provided by our present invention, we possess the ability to cut out lamp after lamp from circuit, and yet maintain a uniform current strength in the remaining lamps and economy of motive power proportional to the diminished resistance, while the normal light-giving power of each lamp not cut out is maintained, and an absence of heating or necessity for any other adjustments than those at the commutator of the machine obviated. These adjustments are preferably made automatic, for we find that with the commutator used by us, as herein specified, a proper adjustment of the commutator being effected when a certain resistance is in circuit, a similar adjustment will, when the resistance is changed, give the same current. In our system we have employed a dynamo-electric machine in which the commutator is constructed of three insulated segments of a ring connected to three armature-coils. The collecting brushes applied to said commutator are supported so as to be movable around the commutator without changing the relative positions of the two collectors. This movement of the collecting brushes is well known in the art. * * * We find in practice, moreover, that we obtain with this automatic regulation of the current strength an independence of speed variations in the machine, it being only necessary to so adjust the speed of running that when the speed is at its lowest the machine shall yet be sufficient in power to maintain the number of lights placed in its circuit. We are therefore able to operate successfully under conditions of motive power variations that have hitherto been recognized as fatal to steadiness of light obtained.

"In United States Patent No. 223,659, January 20, 1880, before referred to, we have described a means of automatically adjusting the commutator collectors of dynamo-electric machines, which method is adaptable to the present case of current regulation. * * * Our present method of operating, therefore, so far as it relates to automatic regulation, is based upon the same principles of operation as our previous invention; and it consists in an improved construction and mode of use of the apparatus employed in Patent No. 223,659.

"We claim:—

"(1) In a current-regulator for a dynamo-electric machine, the combination of a device responding to changes in the main or generated current, a shifting commutator for said machine, and mechanism controlled by said responsive device to shift the commutator to those positions where the current, taken up by said commutator, shall be constant.

"(2) In a current-regulator for a dynamo-electric machine, an electro-magnetic device acted upon by variations in the main or generated current, an adjustable or shifting commutator for the

machine, and mechanism controlled by said electro-magnetic device to adjust the commutator to those positions where the main or generated current taken up by said commutator shall be constant."

The main defense in this case is that the prior Patent No. 223,659, issued to these complainants, is an anticipation of the patent in suit. Upon careful examination of the two patents in connection with the testimony of experts and the able arguments of counsel, I cannot agree with the position taken by the defendants. The object of the two patents, as disclosed by their titles, is different; the patent in suit is for a current regulator for dynamo machines, the earlier patent is for an automatic adjuster for commutator brushes on magneto-electric machines. Current regulation, or "to provide improved means for controlling automatically the strength of the electric current," is the object of the patent in suit, while the object of the prior patent was the construction of an automatic adjuster for commutator brushes, "whereby an automatic adaptation to variations of circuit resistance is secured, and the burning and destructive effects of false adjustments obviated." The design of the present patent is to adjust the commutator to those positions which shall keep the current constant; the design of the prior patent was to adjust the commutator so as to keep the current at its maximum value, or in other words, to adjust the brushes so that their contacts with the commutator segments should be at the neutral points, by which means the difficulty from sparking would be reduced to a minimum. It is true that the means employed in both patents to accomplish these different results bear a close relation to each other. The patentees declare that the earlier method described is adaptable to the present case of current regulation, but they also say that their present method consists in an improved construction and mode of use of the apparatus employed in the prior patent. To construct an automatic adjuster which shall avoid sparking or leakage by bringing the brushes in contact with the commutator segments at the neutral line, or the points of the maximum difference of potential between the segments, and, therefore, of maximum current, may be an important invention, but it is certainly quite a different invention to adjust the brushes of the commutator to positions which shall keep the current constant, independently of the question whether the brushes touch the segments at the neutral points, or whether sparking is avoided.

It is said that the present invention is shown in figures 1 or 2 of the earlier patent. The testimony of defendants' experts seems to find the invention described in figure 1, while the learned senior counsel for defendants appears to reject this contention and turns to figure 2 as an anticipation of the patent in suit. I do not find in figure 2 of the earlier patent the combination of mechanism which forms the subject-matter of the claims of the patent now under consideration. I do not find that which constitutes the important thing in the present invention, namely, the responsive device responding to changes in the main or generated current. In respect to figure 1, the most that can be said is that it imperfectly describes that which was perfected in the subsequent patent now in controversy. It seems to me in other words that the language of the specification is strictly accurate where it declares that the present invention "consists in an improved construction and mode of use of the apparatus employed in Patent No. 223,659."

Upon the subject of infringement I have no doubt. The question is not as to the form of dynamo the defendants may use, or whether their machine may be adjusted by hand to avoid sparking, but the question is whether they use the complainant's invention by the employment of substantially the same means to accomplish the same result, namely, the regulation of the current by means of a device responding to changes in the main or generated current, and this the complainants have shown.

Let a decree be entered as prayed for in the bill.

Decree for complainants.

THE GAULARD AND GIBBS' PATENT. THE WESTINGHOUSE SUIT AGAINST THE SUN ELECTRIC CO. DISMISSED.

Circuit Court of the United States, District of Massachusetts.

IN EQUITY.

WESTINGHOUSE ELECTRIC CO. *v.* SUN ELECTRIC CO. ET AL.

OPINION OF THE COURT.

[August 7, 1888.]

COLT, *J.* This suit is brought to enjoin the defendants from infringing letters-patent No. 351,589, granted October 26, 1886, to George Westinghouse, Jr., assignee of Lucien Gaulard and John D. Gibbs, for improvements in methods and apparatus for the distribution and conversion of electric energy.

The case has been thoroughly and ably presented on both sides. The patent relates to that branch of the art of electric lighting known as the incandescent. The specification states that the "invention relates to the distribution of electrical energy for industrial purposes; and it consists in an improved art or method and an organization of apparatus, whereby the same is carried into effect, by means of which we are enabled to transmit from a central or supply station, through a main conductor, a primary electric current of comparatively small quantity but of high potential, and at a point or points more or less distant, where the said electric energy is to be utilized, to transfer the energy residing in such primary current of high potential into one or more secondary currents of lower potential, but of greater quantity. * * * At a point where the electric current is to be utilized for any suitable purpose—as, for instance, in one or more incandescent electric lamps—we place one or more secondary generators or converters, as shown at C in figure 1. The general principle of our secondary generator is analogous to that of the well-known inductorium or induction coil, with this exception, that, while the induction coil has heretofore usually been employed to transfer electric energy from currents of low potential and great quantity into currents of high potential and small quantity, the function of the secondary generator or converter, as applied in our invention, is precisely the reverse of this, namely, to transfer electric energy from currents of high potential to currents of low potential and increased quantity. We have constructed converters for effecting this result in a variety of forms, all of which involve the same principle. * * * The most important and characteristic feature of our invention is that which renders it possible to make use of alternating and equal positive and negative currents of moderate quantity, but of very high potential in the primary or main line circuit, and to convert these into secondary or induced currents of much greater quantity but of correspondingly lower potential at the place of consumption, which secondary circuits are employed to do the required work. * * * Any required number of converters of the general construction described may have their primary circuits united with or included in the conductors leading from the primary generator. The manner of connecting such converters whether in series, multiple arc, multiple series, or otherwise, will be understood by those skilled in the art to which our invention relates without the necessity of further explanation." The specification then says that one arrangement is indicated in figure 3 of the drawings which shows an arrangement of converters in series. Then follows this disclaimer: "We do not herein claim the connection of the converters in the line in any other arrangement than we have illustrated in the drawings. Figure 3 of the drawings shows an arrangement of converters in series. The defendants connect their converters in what is known as the multiple arc system, which is quite different in construction and mode of operation from the series system.

There are five claims in the patent, the first being for the art or method, and the remaining four claims for the apparatus.

The first question which arises relates to the proper interpretation of the patent in view of the disclaimer. Undoubtedly, as originally drawn, the patent was intended to cover all forms of converters which transferred electric energy from currents of high potential to currents of low potential and increased quantity, whether connected in series, as indicated in figure 3 of the drawings, or in multiple arc, or otherwise. The patent office refused to grant so broad a patent and instructed the applicants that, in order to avoid an interference, they must confine the arrangement of converters to the series system, that being the arrangement shown in the article in *Engineering*, of March 2, 1883, which the applicants declared contained a description of their invention. Thereupon the disclaimer was inserted. An examination of the file wrapper and contents discloses that the patent office believed this patent should be limited to the arrangement of converters in series, and that this was supposed to have been effected by the disclaimer, otherwise an interference would have been declared. The patentees avoided such interference by inserting the disclaimer, and it is too late now to say that the disclaimer means in effect nothing. If we construe the patent to cover broadly a dynamo producing alternate currents of high potential with a single reducing converter, then the disclaimer is meaningless, because such construction would embrace converters connected in multiple arc or otherwise.

The patent states that the invention is for a system of electric distribution; the true scope, therefore, of the invention is not confined to one converter, but to several converters arranged in a system, and, when the patentees disclaim all systems but the series, they should be held to it.

As we have said Gaulard and Gibbs declare that the invention covered by the patent in suit is found in the article in *Engineering* of March 2, 1883. The defendants deny that the article describes converters which transform the current from high potential to low. Whoever may be right, it appears quite certain that the high potential of the primary, and the low potential of the secondary, or the long thin primary wire, and the short thick secondary wire, which become so important in the patent under consideration are not specifically described or shown with clearness in the article in question. The system described in the article was a general one, and was intended to meet the conditions laid down in the English Electric Lighting Act, which provided that the "undertakers" shall not prescribe to householders and others, to whom they supply the current, the use of any particular kind or form of lamp. The Gaulard and Gibbs invention has a two-fold object, says the article; "firstly, it aims at rendering

it practicable for undertakers to supply current at the most economical potential permitted by the terms of their provisional orders; and, secondly, it is intended to make the user independent of the producer, and to enable him to apply the current he receives to any purpose he may please, such as arc lighting, incandescence lighting, the generation of power or of heat." If the article does show a converter which transforms electric energy from high potential to low, it is evident that Gaulard and Gibbs did not at this time regard this as a great discovery, or it would have been more clearly indicated. Undoubtedly, the article was intended to outline a general system to supply to customers currents of high or low potential as might be desired by means of converters connected in series based upon the principle of the Rhumkorff coil, but that this was to be accomplished by means of a primary current of high potential, and secondary currents of low, is not apparent.

Further, if the reducing converter, now made so important, was discoverd by Gaulard and Gibbs, in March, 1883, and constituted such a great invention, why did it not form the subject-matter of their subsequent American patent of April 29, 1884, and British patent of September 13, 1882?

These things go to prove that the prominence given to the reducing converter in the patent in suit was based upon something else than the article in *Engineering*. I am led to think that it was based upon the fact that, between the date of the article and the date of the patent in suit, other inventions had come to light, and that it was these improvements which induced Gaulard and Gibbs to set up the claim they make in their last patent.

In the patent granted to E. Thomson, July 14, 1885, the converters are arranged in series. The object of the invention was to provide a safety switch for the converters, but we there find described the primary or main current of high potential and the secondary current of low potential. The specification says, "The secondary coil is wound with such coarse wire, and the lamps used therewith are of such low volt potential as not in itself to produce dangerous discharges or shocks." Thomson seems to take it as a matter of course, in view of the prior state of the art, that there was no invention in reduction from high potential to low through a converter.

But the most important improvement was made by Zipernowski and Déri in their English patent, of March, 1885. This patent describes minutely a system of distribution by induction through potential reducing converters combined in multiple arc, and it includes an alternating current dynamo generating a current of high potential.

We see then that the state of the art in 1882, when the article in *Engineering* was written, and in 1886, when the patent in suit was issued, was quite different. It became very important, therefore, for Gaulard and Gibbs to obtain a patent for a single reducing converter, however it might be combined with others in a system. I think the importance given to this point in the patent an effort to expand the real invention of Gaulard and Gibbs as contained in the article in *Engineering*, and that the patent office intended and did in effect limit the patentees to all they were fairly entitled to, namely, the arrangement of their converters in series in a system of electric distribution.

But assuming that our interpretation of the effect of the disclaimer is wrong, and that Gaulard and Gibbs are entitled under their patent to claim the exclusive right to a converter which transfers energy from high potential to low in combination with a dynamo producing alternating currents, can so broad a claim be sustained in view of the prior state of the art?

To uphold this position, of course, Gaulard and Gibbs have to go back to the article in *Engineering* of March 2, 1883, as the date of their invention, because this form of converter in combination with an alternating dynamo is clearly shown, as has been observed in the Thomson, Zipernowski and Déri patents of 1885. But, admitting that the date of the invention was March 2, 1883, I have much doubt whether Gaulard and Gibbs could obtain a lawful patent for so broad a claim. The counsel for the plaintiffs in his closing argument admits that the induction coil or inductorium or converter, in its general sense, as a device used for taking off from the line at different points, a portion of the electric energy whether of the same or higher or lower potential, was well known. The article in *Engineering* states that the secondary generator or converter was based upon the same principle as the Rhumkorff coil. In the English patent granted to Paul Jablochkoff, November 9, 1877, we find described a system for producing and dividing electric lights, which consisted in carrying a main alternating current round an unbroken circuit and transferring its energy by means of induction coils to consumption circuits at the points where it was to be used. The converters are placed in series with one or more lamps in the secondary of each converter. But it is said that Jablochkoff contemplated a conversion from low to high potential, the reverse of Gaulard and Gibbs. At the same time, it was well known that the converter would transfer energy from high to low, or low to high, as the primary wire was longer or shorter. Was it invention for Gaulard and Gibbs simply to reverse the coils and transfer the energy from high to low?

In the English provisional specification of Edwards and Normandy, November 13, 1878, the inventors propose to use either interrupted or alternating currents with a converter near every place where the light is to be produced. The specification says, "At or near every point where it is required that a light shall be produced, we arrange a coil (or series of coils) of insulated metallic wire or ribbon (preferably surrounding a bar or wires of soft iron) through which coil or coils the current from the principal wire first described can be passed when desired, or cut off by means of a key or lever. Round or adjacent to each coil of insulated wire described, we form one or more secondary coils, of insulated, metallic wire or ribbon, arranged so that the passage of the rapidly intermittent current of electricity, as described, through the primary coil or coils generates a corresponding amount of electricity in each of the secondary coils. * * * In order to facilitate the production of the induced electricity, *and to diminish its intensity and increase its quantity*, we prefer making the coil or coils in which the electricity is induced of a number of insulated wires or ribbons made up into a bundle or rope, the ends of the wires or ribbons at each end of the bundle or rope being in metallic contact with each other, which united ends are then joined to the conductor, conveying the induced electricity." Here is found distinctly stated the principle of a reduction from high potential in the primary to low potential and increased quantity in the secondary, which Gaulard and Gibbs assert is their great discovery.

The patent to J. B. Fuller, November 26, 1878, is for an improvement in induction apparatus for lighting by electricity. This invention embraces converters arranged in series like those of the patent in suit to be operated upon by an alternating current. It is not stated whether the potential is to be raised or lowered in the converters, but the drawings appear to indicate that it was to be raised.

In the English provisional specification of J. H. Johnson, December 24, 1878, while the inventor contemplated the raising of the potential in his converters, yet he says, "the apparatus may be connected together * * * in such manner as to augment either the tension or the quantity of the current."

Thomas A. Edison took out a patent, May 29, 1883 (the application having been filed August 14, 1882), for an apparatus for translating electric currents from high to low tension. In his invention he uses a continuous current of high tension in the main circuit, and reduces it to a continuous current of low tension in the secondary circuit.

This incomplete review of the prior state of the art would seem to show that, at the date of the article in *Engineering*, there was no invention in a single converter which transferred energy from high to low potential, as distinguished from a conversion from low to high. It seems to have been assumed in prior patents as a matter of common knowledge that, by the laws governing the inductorium, or converter, the electric force transferred could be either of the same potential or of greater or less, as might be desired. It required something further, something that might be called invention, to solve the problem of a successful system for electric distribution. Gaulard and Gibbs undoubtedly believed that, in the article in *Engineering*, they unfolded to the world a description of a successful system. So far as their system was a new invention, and is found incorporated in the patent in suit, they are entitled to be protected. But they are expressly limited by their disclaimer to the series system, and, therefore, the defendants who use the multiple arc system do not infringe.

Without entering further into the defenses raised, I am satisfied, for the reasons given, that the bill should be dismissed.

Bill dismissed.

THE CUSHMAN TELEPHONE CASE.

The following is an abstract of Judge Blodgett's opinion in his decision against the Cushman company, July 20, noticed in the ELECTRICAL ENGINEER for August:

"The questions presented are purely questions of fact. If Dr. Cushman did actually produce and put in use, to the extent claimed by him, the apparatus constructed, as described by him, so as to transmit articulate speech to a distance by means of an electric current, then, I should think there would be no doubt that such fact should defeat the Bell patents, as the apparatus described by Cushman is conceded to be substantially identical in principle, construction, mode of operation, and result with the Bell devices. It is conceded that in order to defeat a patent by proof of prior knowledge and use of the device covered by the patent, such proof must be so clear and satisfactory as to leave no room for reasonable doubt.

"It is not my purpose to go into a complete analysis of the voluminous proofs in this case. It is sufficient to say that there is no proof in the records, save from Dr. Cushman himself, of the construction and use of the first apparatus described by him, through which he heard in the office at Racine the peeping of frogs in a swamp several miles away, and which, as he says, led up to the experiments which he, with the assistance of his brother, W. P. Cushman, and B. T. Blodgett made the operative telephone of 1851. The evidence in this case is quite convincing

that such an apparatus as he describes his lightning-arrester to have been would not transmit the peeping of frogs or articulate speech, as the glass plate which he says covered the top would have entirely excluded the sounds from the magnets.

Both W. P. Cushman and B. T. Blodgett, who it is claimed, aided in the construction of the four talking boxes in the summer of 1851, are dead, and the only witnesses aside from Dr. Cushman himself are the workmen said to have been employed in putting up the telegraph line from Racine westward. I think there is nothing shown by their testimony to have been accomplished by these experiments which could not be attributed to the action of a device operating as an acoustic telephone or the ordinary relay telegraph instrument then in use to transmit signals by clicks. That some kind of experiments were made in the presence of these witnesses is probably true, as I can not believe that these men would intentionally swear falsely, but I do seriously doubt whether they witnessed at that time all the results to which they now testify. After these experiments upon the line, we have the line from the back room of the Racine telegragh office and from White's shop to Wright's carpenter shop, and the experiments there. That such a wire was run from one or both these places I can not doubt, and I think it possible that some words may have been transmitted from one end to the other of this wire; but this result can easily be accounted for by the action of the device as a simple acoustic telephone, as the line ran direct from one point to the other, and the distance was only about 300 feet.

"The next alleged use is that of the wires between Dr. Cushman's house in Racine and the farm of W. P. Cushman, six miles away. The proof as to this use rests upon the evidence of Dr. Cushman alone, and I do not think the attempted corroboration of his testimony by Josiah B. Cushman's testimony is reliable. The practical use of these 'talking boxes,' in 1854 and 1855, does not show results which may not have been obtained by the acoustic telephone.

"My conclusion from a careful reading and consideration of this mass of testimony is that Dr. Cushman, with the aid of W. P. Cushman and B. T. Blodgett, in Racine, during the summer of 1851, did make a device containing magnetic coils through which spoken words could be and were transmitted at short distances; that the transmission was faint and the words difficult to hear, and the attempt to talk through them was often a total failure, and occasionally when all conditions were favorable, only a partial or meagre success was obtained. * * * I have no doubt from the proof that the machines made by Dr. Cushman, W. P. Cushman, and B. T. Blodgett in 1851 were in all practical respects as good as any that were made afterwards by Dr. Cushman or those who assisted him. Orrin White tried to improve them, and afterward Joshuah B. Cushman made an effort in the same direction, but they were so imperfect in their operation as to offer no promise to anyone of their future possibilities. These considerations compel me to the conclusion that all the testimony, when taken together, falls short of establishing beyond reasonable doubt the fact that Dr. Cushman in 1851 invented the telephone, and what was done by him must and should be treated as at best only an abandoned experiment.

"I do not think the testimony when fairly considered shows that Dr. Cushman produced at Racine or elsewhere prior to the invention of Bell a practical, operative telephone of any kind. He gave the world nothing—what he did, if he did anything but make an acoustic telephone—was suffered to die in embryo or germ, before any valuable or useful fruition. I do not believe the machines made by him during these experimental years were so far perfected as to be of any practical value, or to even suggest that they might be so improved as to become valuable and useful. If a word could be occasionally transmitted through them, the result seems only to have excited curious wonder in the south, and did not challenge the attention of practical men, as did the first exhibitions of the Bell device. When the Bell telephone was brought to the attention of the public its value and utilities were grasped at once. It was accepted as a great invention by the general public as soon as its operation was seen, and I can see no reason why the public would not as readily have comprehended its advantages and value in 1851 as in 1876, had the machine been so far developed as to give substantial promise of what Bell accomplished."

SEMI-ANNUAL CONVENTION OF EDISON COMPANIES.

The association of Edison illuminating companies met Wednesday, August 8, 1888, at Nantasket hotel, Nantasket Beach, Mass., in their eighth semi-annual convention. The total number of representatives present during the sessions of the convention amounted to sixty members. Several other gentlemen were present by invitation during some of the sessions.

New York city was fairly well represented by E. H. Johnson, J. H. Vail, W. J. Jenks, respectively the president, superintendent, and municipal department manager of the Edison Electric Light company in the metropolis; electricians Chas. Wirt and H. T. Edgar, and expert L. Steininger; John I. Beggs, vice-president and general manager of the Edison Illuminating Co.; C. J. Field, chief inspector Edison United Manufacturing Co. and J. W. Schrorder.

Other delegations were as follows:—

Boston: C. L. Edgar, superintendent of the Edison Illuminating Co., S. B. Paine, A. S. Knight, and Hubbard Breed, who is the treasurer of the company with which Mr. Edgar is connected.

Elgin, Ill.: Chas. Westervelt, the Edison company's general manager.

Wyoming: R. M. Jones, general manager of the Laramie Electric Lighting Co.

Brockton, Mass.: G. W. Palmer and W. L. Garrison.

Other Massachusetts delegates were Albert F. Dow and J. H. R. Ward of Fall River; C. E. Price, New Bedford, Wm. M. Brock and G. W. Russell, Lawrence.

General manager A. M. Renshaw, Washington, D. C., was the only registered representative from that city.

Magnus Pflaum, McKeesport, Pa.; H. Ward Leonard, of Leonard & Izard, Chicago; F. G. King and A. L. Smith, Appleton, Wis.; Jno. R. Markle, C. P. Gilbert, Detroit; Wilson S. Howell, New Brunswick, N. J; F. E. Jackson, B. F. Card and F. R. Upton, Harrison, N. J.; president Thomas P. Merritt and secretary F. N Boyer, Reading, Pa.; president Geo. H. Kirchway and director H. L. Browning, Albany; manager W. L. Turner and treasurer F. E. Drake, Columbus, O.; manager E. H. Brooks, Lebanon, Pa., superintendent J. E. Giles, Hazleton, Pa.; superintendents E. B. Greene, Altoona, Pa., and H. K. McKay, Birmingham, Ala.; Samuel N. Frump, J. A. Lightipe and F. L. Gilpin, Wilmington, Del.; manager J. B. G. Roberts and superintendent Maurice Hooper, Westchester, Pa.; secretary H. Brewster, Rochester, N. Y.; superintendent J. S. O'Brien, Wilkesbarre, Pa. Others at the hotel and present at some of the meetings as delegates or in other capacities were general agent H. McL. Harding, of the Sprague Motor Co.; W. A. Hill, W. H. Atkins, E. L. Caldwell; H. H. Niles, A. O. Shepardson, W. H. Francis, W. D. Marks, Philadelphia, J. R. McLaughlin, Detroit, Chas. Hewitt, Patterson, N. J., N. C. Martin of New York, and W. I. Barker, Boston, both of the *Electrical World;* secretary F. J. Boynton of Boston; R. F. Ross, *Modern Light and Heat*, Boston; Capt. Brophy, B. F. Simmons, and F. C. Lockwood, representing the *Western Electrician.*

The meeting was called to order by the president, John I. Beggs, at 11.30 A. M., and in opening the convention he congratulated the association on the large number of representatives, and the very numerous companies represented.

Some interesting load diagrams showing comparisons of load variations at Columbus, Ohio, were presented by Mr. Turner, manager of that company.

Electric motive power and its widely increasing application was then discussed.

At the afternoon session of Wednesday, new officers of the association were elected for the ensuing year as follows:—

President, John I. Beggs; vice-president, C. P. Gilbert; secretary, J. H. Vail; treasurer, Wilson S. Howell; executive committee, A. L. Smith, F. R. Upton, C. L. Edgar, J. P. Merritt, R. M. Jones.

At the evening session the association and visitors were entertained by a very able and exhaustive paper, presented by W. J. Jenks, on the subject of lightning and its effect on electric light, telephone and telegraph systems. This paper was splendidly illustrated by numerous stereopticon views. This was followed by a series of stereopticon views exhibited by Mr. Harding, showing the principal features of the Sprague system of electric railways, as well as interesting and novel applications of motive power.

At the opening of the session on Thursday, a paper was presented by Mr. Jackson, assistant electrician of the Lamp company, on the subject of the high economy municipal lamp and the result of its application in Edison stations. This was followed by an address by Mr. Upton on a similar subject.

A paper on the subject of feeder equalizers and regulation of electrical pressures on the three-wire system was presented by Charles Wirt. This was followed by another paper by H. Ward Leonard on the subject of proportioning conductors in the system of electric light. Both of these papers were very accurate and to the point, and showed a comprehensive grasp of the different questions involved.

Another interesting report was made by Mr. Jenks on the growth of the Edison municipal system. Mr. Jenks also gave a summary of the work done by the standardizing bureau of which he is director.

Several interesting discussions were had on the enlarging field for applied electricity, and other subjects of importance to the association.

The executive committee reported that they had selected Kansas City as the best locality for the next meeting of the association. This selection was approved, and the convention adjourned to meet in six months.

. . . . THE only right way to put up an installation is to reduce all chance of a mishap to a minimum by putting in the best possible work.—*J. A. Jeckyll.*

A DECISION IN THE PATENT SUIT OF ROOSEVELT *vs.* LAW TELEGRAPH CO.

In the suit of Roosevelt *vs.* The Law Telegraph Co., a decree was recently issued by the United States Court in favor of the plaintiff.

The above suit was brought for infringement, by what has been known as the "Law Battery," on the Leclanché patent of November 16th, 1880, which covers the "Gonda" Prism battery manufactured by the Leclanché Battery Co. The opinion of the Court is an exhaustive one, covering every point in the case, and sustaining the Leclanché patent in a very broad sense. Injunction has been issued against the manufacture and sale of the said "Law Battery."

MISCELLANEOUS.

FOUR of the largest manufacturers of copper wire for electrical purposes in the United States used in 1887, 13,500,000 pounds of copper.

THE WESTERN UNION operating room at 195 Broadway now contains 505 desks, exclusive of those in the Commercial News department, and above the switch-board. There are 800 employés on the pay roll of the operating department.

THE ELECTRICAL COURSE AT RUTGERS COLLEGE.

The trustees of Rutgers College have decided to establish an electrical course in the scientific school of the college.

This course is parallel with the other four-year courses of the school, and those who complete it receive the usual degree of Bachelor of Science.

The studies include mathematics through surveying; a full course of chemistry with laboratory practice, embracing qualitative analysis and the elements of quantitative analysis; physics, using the latest edition of Ganot in the original French, and such works as Stewart and Gee for physical laboratory practice. A select course of draughting in the first year, and extensive drill in the use of tools during the second year are preparatory to construction of apparatus later on. The works of Cumming, Kempe, and others of a specifically electrical character, are used in the third and fourth years, in conjunction with treatises on the various prime movers.

Natural history; the usual English branches; mental and moral philosophy; French; German; composition and speaking; and extemporaneous debating are included in this course, to insure a rounded development. The purpose is not to graduate electrical engineers, but men fitted to pursue distinctively electrical occupations, with a good general basis. A good amateur workshop and a physical laboratory are to be fitted up, and special stress will be put on ability to manipulate well. The course in general physics will include a thorough drill in problems, particularly such as enforce fundamental principles, and students will be required to use French and German freely.

The preparations are already sufficiently advanced to fulfill requirements of the first year, and there is a good prospect that ample accommodations will be ready for pupils at the successive stages of the course. No *special* students are desired, but every one is expected to take the full curriculum.

ROSE POLYTECHNIC INSTITUTE.

The Rose Polytechnic Institute, is one of a number of schools in the United States which are especially devoted to the education of civil and mechanical engineers. It owes its existence to the generosity of the late Chauncey Rose, of Terre Haute, Ind., who bequeathed something more than a half million of dollars for its establishment and support. It is one of the youngest of the technological schools of the country, having been opened for instruction in the year 1883. One of the peculiar features of the institute is the extensive "shop practice" of the students in mechanical engineering. Not only are machines designed and working drawings made, but actual construction is required and is made possible in extensive workshops, the equipment of which has cost over forty thousand dollars.

Especial attention is given to the study of electricity and its applications, for which excellent facilities are provided in the equipment of the extensive laboratories.

The plan of the institute is to restrict the attendance to such an extent as to realize the benefits arising from small classes.

ADDITIONAL RULES OF THE NEW YORK BOARD OF ELECTRICAL CONTROL.

The following were added to the Rules and Regulations of the Board of Electrical Control, July 2d, 1888:—

Day circuits.—All circuits which ever carry a current exceeding 500 volts, between 9 A. M. and 4 P. M., must be painted red for a length of two feet at each insulator.

Number of circuit.—Every electric light wire carried on poles must be indicated by a number plainly marked on each cross-arm under the insulator.

Stations.—All circuits must be tested every hour when in operation, and when a ground comes on, effort must be made to remove it at once; failing in this, the current must be discontinued until the insulation is restored.

Certificate of inspection.—From and after the first of August, 1888, no company shall do business of arc electric lighting in the City of New York without a certificate of the board, granted on the recommendation and after inspection by the expert of the board, to the effect that its lines comply with all the rules and regulations of the board, and that its plant is in proper condition for the doing of its business. The force of the certificate to continue until changes are made, of which the board must be notified and approve, or so long as the plant and conductors remain in the same condition as when inspected.

The following were added to the Rules and Regulations of the Board of Electrical Control, July 16th, 1888:—

Loops.—No unused loops from electric light circuits shall be allowed to remain after lamps are taken away, except in cases where it is positively known that the lamp will be required again within three months, and where there is no underground conduit for that class of circuits.

Linemen.—All linemen must wear a badge, in a conspicuous place, giving the name of the company by whom they are employed, and a number.

TESTS OF A SPRAGUE AND AN EDDY MOTOR.

BY FRANK P. COX, B. S.

SPRAGUE MOTOR.—1 H. P.

Current	8.29
Potential	117.84
Electrical horse-power	1.31
Mechanical horse-power	1.06
Efficiency	81%

EDDY MOTOR.—½ H. P.

Current	17.99
Potential	27.76
Electrical horse-power	.669
Mechanical horse-power	.43
Efficiency	64%

Thomson's graded galvanometers were used for determining current and potential; a Tatham dynamometer to determine the mechanical horse-power.

SOME NOTABLE DYNAMO TESTS.

A test is reported of an Edison-Hopkinson dynamo, made by Mather & Platt, of Salford, England, of a type giving 320 amperes and 110 volts at 780 revolutions, which gave a commercial efficiency of 93.23 per cent.; loss in core 1.94; in field 1.66 and in armature 3.17. The same machine, used as a motor gave an efficiency of 93.79, and on the double conversion an efficiency of 87.05 was obtained, excluding loss in leads. The Manchester dynamo; a compound wound machine of the same makers, but of a different type, gave a mean result of a number of trials, of 77.5 per cent. double conversion over a distance of 100 yards.

A NEW INSULATING COMPOUND.

A new insulating material, described in the *Chronique Industrielle*, has just been produced. It is composed of one part Greek pitch and two parts burnt plaster, by weight, the latter being pure gypsum, raised to a high temperature and plunged in water. This mixture, when hot, is a homogeneous, viscous paste, and can be applied with a brush, or cast in molds. It is amber colored, and possesses the insulating properties of ebonite, and can be turned and polished. Its advantage is its endurance of great heat and moisture without injuring its insulating properties. —*Electrical World.*

THE TELEPHONE.

THE AMERICAN TELEPHONE & TELEGRAPH CO.'s long-distance lines seem to be proof against the storm blasts of summer as well as the blizzards of winter. Not a single private wire has been interrupted during the recent wind storms; another proof of superior construction.

THE next meeting of the National Telephone Exchange Association will be held in the City of New York, at the Hotel Brunswick, commencing Tuesday, September 4, 1888. The hotel is on the European plan. Rooms may be engaged direct, or the secretary will cheerfully attend to such business on request of any member of the association.

THE SOUTHERN NEW ENGLAND TELEPHONE COMPANY is to put up a large building on Court street in New Haven. It will contain, besides the Central and Telephone Exchange, the executive offices of the company and a public telephone station. The change will materially improve the service.

THE life saving stations along the south coast of Long Island

are all to be connected with each other by telephone, and those isolated from the mainland are to be connected with the nearest village. Surveyor Boland, of the treasury department, is at present making a survey for the laying of a cable between Montauk Point and Rockaway Beach. The work will probably be completed by October 1.

THE office of the secretary of the National Telephone Association is now in room 512, 18 Cortlandt street, New York city (the Metropolitan Telephone Co.'s building). The treasurer's office remains in room 501 of the same building. Telephone call "531 John."

DURING the agitation at New Orleans, La., regarding the ordinance regulating the telephone charges at $50 a year, the representatives of the telephone interests did not think the city had power to regulate the price of telephones under existing ordinances, and thought that the present price is a fair one considering that this climate is more dangerous to the apparatus than that of other large cities. The following comparative table of rates was made up from information obtained by the committee on fire and lighting, the telephone company and the Chamber of Commerce:

Chicago	$125	St. Louis	$100
Philadelphia	120	New Haven......50 to	75
Baltimore	100	Washington	100
Cincinnati	100	San Francisco..60 and over	
Atlanta	60	Pittsburg..........84 to	600
Cleveland	180	Boston	120
Milwaukee......60 to	100	Rochester	64
Kansas City	72	Brooklyn	120
New York.......150 to	180	New Orleans	96
Louisville.........72 to	96		

The committee did not see its way to report favorably upon the ordinance, but thought that stirring up such matters did good, as bringing about the obtaining of useful information.

LIGHTNING CONDUCTORS TO BE DISCUSSED BY THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

It is announced that the organizing committees of Sections A and G of the British Association for the Advancement of Science, have arranged a joint discussion on "Lightning Conductors," to be held at the Bath meeting, in September. Mr. W. H. Preece, F. R. S., will open the discussion, and Professor Oliver J. Lodge, D. Sc., F. R. S., will defend the position he advocated this year before the Society of Arts.

AN ELECTRIC RAILWAY FOR LONDON.

At a meeting of the shareholders of the City of London and Southwark Subway Co., held at Winchester House on Tuesday, the directors were authorized to make arrangements for the working of the line by electricity. The subway, which, when complete, will extend from the city side of London bridge to the Swan at Stockwell, with several stations between those two points, was originally intended to be worked on the endless cable principle, which is said to give such satisfactory results in America, but the directors of the company have, after careful investigation, arrived at the conclusion that the line can be more thoroughly, efficiently, and economically worked by electricity. Several eminent firms have, they say, expressed their readiness to undertake the work, the system which they propose to adopt being that of continuous conductors, and are so sanguine of success that they have offered to work the line on favorable terms for a number of years. One or two of the shareholders present evinced opposition to the action of the board in discarding the original idea of a cable, for what, in their opinion, was the more risky electrical system, but eventually the resolution proposed by the chairman was sanctioned. It was stated during the proceedings that the engineer hopes to get that portion of the subway between the city and the Elephant and Castle completed by the end of the year.—*The Telegraphic Journal and Electrical Review* (London), Aug. 17.

BRITISH EXPORTS OF TELEGRAPHIC WIRES, &c.

The satisfactory features of the board of trade returns for July, issued on Wednesday last, are not reflected in the exports of telegraphic apparatus. The exports of metals, ironwork and machinery were exceptionally favorable both for July and for the previous six months, but the exports of telegraphic wire and apparatus were exceptionally small. The following is a comparative statement to date:—

Exports of telegraphic wires and apparatus connected therewith.

	1886.	1887.	1888.
1st Jan. to March 31st	£124,074	£131,879	£88,077
1st April to June 30th	354,331	56,933	156,136
Six months	478,405	188,812	244,213
July	219,463	195,950	21,571
Seven months	£697,868	£384,762	£265,784

The July exports this year have been almost the smallest of any month so far, while in 1887 and 1886 the July exports were up to date by far the largest.—*The Electrician* (London), Aug. 10.

ELECTRIC LIGHT AND POWER.

THE WHITIN MACHINE CO., Whitinsville, Mass., have increased their electric plant, adding 135 arc lights. The Waterhouse Electric & Manufacturing Co., of Hartford, Conn., were given the order, as the plant installed by them last season was entirely satisfactory.

THE WESTERN ELECTRIC CO. of Chicago, is installing an arc light plant for the Brown Bros. Manufacturing Co., Chicago.

AT Urbana, the common council has awarded to the Excelsior Electric Co., F. W. Horne, Chicago western agent, the contract for installing a 120 arc light plant in the city.

THE WILLIMANTIC ELECTRIC LIGHT CO., Willimantic, Conn., have again increased their plant with 35 Waterhouse arc lamps and another dynamo.

THE OREGON IMPROVEMENT CO. have ordered for their wharves, machine shops and railroad station a Waterhouse arc and incandescent plant.

THE FORT WAYNE JENNEY ELECTRIC LIGHT CO. is building a very large lighting station in this city, near 80th street and Avenue A, East River.

SAN DIEGO, Cal., has adopted the Westinghouse system of incandescent light, and the plant has been ordered. The capacity will be 1,300 lights, and it is expected the town will be lighted about October 1st.

THE WESTINGHOUSE ELECTRIC CO. has taken up the alternate current motor of Mr. Nikola Tesla, and has now for some time been carrying on experiments under the supervision of the inventor looking to the commercial development of the motor. The results already accomplished are, it is understood, very satisfactory indeed, and this remarkable invention is likely to be embodied in practical work-day motors at an early day.

ON seeing the Waterhouse light recently installed for the Joliet Electric Light Co., Joliet, Ill., the Joliet Steel Co., placed their order for an arc and incandescent plant with the Waterhouse Electric and Manufacturing Co., of Hartford, Conn. The Waterhouse incandescent system has been ordered for the lighting of a fashionable seaside resort in England.

THE general offices of the Consolidated Electric Light Co. and of the Sawyer-Man Electric Co. have now been some weeks established in their new premises at 510 West Twenty-third street, New York, to which address all communications should be sent.

The office of H. R. Garden, vice-president and general counsel, will remain in the Mutual Life building, 32 Nassau street.

THE AMOSKEAG MANUFACTURING CO., of Manchester, N. H., may be said to have "a large and well-selected assortment" of electric lighting machinery. The outfit consists of five No. 8 Brush dynamos, and five No. 7, with an aggregate lighting capacity of 370 lights of 2,000 candle-power; 21 Weston 10-light dynamos of 2,000 candle-power each; one Thomson-Houston 45-light dynamo of 1,200 candle-power; one 300-incandescent light Edison dynamo; one 75-light Forsaith, and one American 50-light machine. Three of the Brush dynamos of the No. 7 pattern have been in use in the No. 4 mill as long as any such machine in the state, and are still in very good condition. One of the Weston dynamos has been in operation seven and one-half years, and still gives excellent satisfaction.

THE NEW ENGLAND INSURANCE EXCHANGE recently issued the following circular:

To Companies and Agents:

Following is a complete list of electric light companies, or "systems," that have complied with all the requirements of this "Exchange," and whose installments and apparatus will entitle the assured to rebate in tariff rates, in accordance with vote of March 31, 1888, heretofore promulgated.

No allowance will be made for the apparatus of any company or system not named in the following list:

American Electric Manf'g Co., Ball Electric Light Co., Bernstein Electric Light Co., Brush Electric Light Co., of Cleveland, Ohio; Edison Electric Light Co., Edison United Manf'g Co., Fred. M. Kimball & Co., of Boston; Loomis Electric Light Co., Mather Electric Light Co., Sawyer-Man Electric Co., Schaefer Electric Manf'g Co., Sun Electric Light Co., Thomson-Houston Electric Co., Tremont Electric Lighting Co., United States Electric Lighting Co., Waterhouse Electric and Manf'g Co., Westinghouse Electric Light Co. Respectfully, ARTHUR A. CLARKE.

S. E. BARTON.

Foreign.

Austria.—Some time ago the proposal of Messrs. Siemens and Halske to establish a central electric light station in the very heart of Vienna was reported. Work has since then steadily progressed, and the firm have now invited householders in the district to send in particulars of their requirements for light. The concession was given on condition that the contractors would not

charge more than 2.75kr. per lamp hour, but in order to get sufficient custom they will very probably have to lower the price. Curiosity prevails in electrical circles as to how low the charge will have to be fixed in order to induce a sufficient number of the somewhat conservative householders of the inner town to become subscribers. The next central station will be that in Mariahilf. The distribution will be on the direct low pressure system, and will have to compete with another central station projected by Messrs. Ganz & Co. for the same locality, where the distribution will be by means of transformers. Some activity is also displayed by the Deutsche Allgemeine Elektricitäts Gesellschaft, of Berlin, who are contemplating the erection of a branch establishment in Vienna for the general supply of electricity.

Cuba.—The Havana Electric Light Co., of Jersey City, has been incorporated by J. del Calvo and others, with a capital stock of $15,000.

France.—ELECTRIC LIGHT INSTALLATION AT TOULOUSE.—An electric light installation has just been erected by the Toulouse Gas Co. in the Theâtre du Capitole in that town. Current is supplied by two 500-light Breguet dynamos, each being driven by a two-cylinder Otto gas engine of 50 h. p. The dynamos and gas engines are placed in a cellar situated a short distance from the theatre. There are 1,000 lamps of 10, 16 and 20 c.p. installed, and they have been fixed to the existing gas fittings. The lamps are supplied from two circuits, which are so arranged that should an accident happen to one, the lamps in the other will not be extinguished. The lighting is said to be very satisfactory, and the installation has been carried out under the superintendence of M. Brouardel, manager of the Compagnie Française du Centre et du Midi.

Germany.—UNDERGROUND CABLES IN BERLIN.—Some time ago a committee was appointed in this town to carry out a comprehensive series of experiments with underground cables as used for electric lighting urposes. The experiments were made partly with sections of cables used in the various central station supply systems, and partly with cables specially laid for the purpose in the works of Messrs. Siemens and Halske. The experiments are now nearly completed, and the results will be communicated at an early date in the form of a paper on underground conductors to the Berlin Society of Electricians.

THE SUPPLY OF MOTIVE POWER FROM CENTRAL ELECTRIC LIGHT STATIONS.—The Berliner Elektricitäts Werke are now supplying current for driving electromotors. They have issued a circular to their customers, pointing out that the capital outlay for an electromotor is less than that for an equivalent steam or gas engine, whilst the expense for attendance and water is entirely avoided. The cost of lubricants is also greatly reduced. The company are ready to supply current for motors varying in size from $\frac{1}{16}$ h. p. to 12 h. p. The maximum current required for a $\frac{1}{16}$ h. p. motor is 1 ampere; for a $\frac{1}{4}$ h. p., 3 amperes, for a $\frac{1}{2}$ h. p. $5\frac{1}{2}$ amperes; for a 1 h. p., 10 amperes; for a 5 h. p., 45 amperes; and for a 12 h. p., 105 amperes. If the customer requires the motor during the day time only the charge for current is the same as where the current is used for lighting; but if the motor be required from sundown till eleven at night the company reserve to themselves the right of making an additional monthly charge of 1s per ampere, should the exigencies of the lighting service render it necessary to place this restriction upon the use of motors. On the assumption that the motor is in use for 3000 hours annually, the cost of 1 h. p. hour varies from $5\frac{3}{4}$d. for the smallest motor to $3\frac{1}{4}$d. for the largest. For a 2 h. p. motor the cost is about $3\frac{1}{2}$d. per horse-power hour.—*Industries.*

New Zealand.—The city couucil of Wellington has accepted the tender of the Gülcher Electric Light Co., of London, for machinery, buildings and plant for lighting the city with 480 Edison-Swan lamps, each of 20 c. p. The contract price is £1,750 per annum for the first five years, and an offer was made to run on for another five years at £1,600 per annum, should the council not decide to purchase the plant at the end of the first period. The Gülcher company was, we are informed, the only one tendering, although the matter was freely advertised in England, America and, we believe, on the continent.

PERSONAL MENTION.

DR. BENJAMIN FRANKLIN GOODRICH, president of the B. F. Goodrich Co., and the Goodrich Hard Rubber Co., Akron, Ohio, died August 3d.

MR. L. D. WAKEMAN has been engaged by the New York State Agency, of the Sprague Electric Railway & Motor Co., to look after its interests in the city of Buffalo.

MR. T. C. HATHAWAY, JR., of New Bedford, Mass., a graduate of the Massachusetts Institute of Technology, is under engagement with the New York State Agency of the Sprague Electric Railway & Motor Co., and is located in central New York.

MR. WILLIAM D. HIGGINS, who was recently engaged as special agent of the Sprague Electric Railway & Motor Co., has been placed in charge of the Buffalo office of the New York State Agency, Edward E. Higgins, manager.

MR. J. HOWARD PRATT, JR., late Instructor in Physics at Cornell University, has been appointed Professor of Physics and Mathematics in Illinois College, Jacksonville, Ill. Mr. Pratt will assume his new duties at the beginning of the college year in September, and in view of his known interest in electricity, together with his wide acquaintance with its science and the arts built upon it, we may predict that that department of physics will be ably presented to the students at Jacksonville.

THE NEW YORK STATE AGENCY, recently established by the Sprague Electric Railway & Motor Co., with headquarters in Buffalo, is working up a large amount of business both in railway and stationary work. Its manager, Mr. E. B. Higgins, reports the interest in electrical transmission of power to be unexpectedly great, and the prospects for immediate work are very encouraging. The agency has just sold a 5-h. p. Standard motor to be used in the large dry goods establishment of Barnes, Hengerer & Co., of Buffalo, for running a large number of sewing machines. Current will be supplied by an Edison dynamo used in lighting the building.

MR. ELIAS E. RIES, of Baltimore, has been spending some time in Boston, where he is looking after his electrical interests. Mr. Ries exhibited there a very interesting working model of his electric traction increasing apparatus for street railway motors, an invention which is eliciting considerable attention on the part of electricians and those interested in street railways. By the aid of this invention, street cars operated by electric motors are said to be able to climb grades as steep as 15 to 20 feet in 100, without the slightest difficulty. A very ingenious and effective system of braking is also employed in connection with the traction increasing apparatus, by means of which it is possible to stop a car running at full speed down a steep grade within a very short distance. The cars on the working model ascend and descend grades of 45 per cent. with ease; and in the case of the street car model, the magnetic adhesion between the wheels and rails seemed not appreciably affected by placing oil, mud or water upon the track. Many gentlemen largely interested in street railways from various parts of New England, have examined the models.

MANUFACTURING AND TRADE NOTES.

W. S. HILL, 13) Oliver street, Boston, manufacturer of electrical apparatus, issues a circular and price list of dynamos, motors, arc and incandescent lamp switches, fitting, etc.

THE SPRAGUE CO., have just sold one 20 and one 30 h. p. motor, to parties in Nebraska, to be used in operating machinery for making brick.

THE SPRAGUE COMPANY have received from Tokio, Japan, a very commendatory account of the performance of an electromotor fire pump, supplied by them some time since for use in the Imperial palace.

MESSRS. CHAS. A. SCHIEREN & CO., of New York, have recently opened a branch house at 46 South Canal street, Chicago, where they carry a full line of their goods. Standard, short lap, electric, and leather link belting; also raw hide and tanned lace leather.

Mr. Emil Gabel, formerly president of the Gabel Belting Co., of Chicago, has charge of this branch.

MESSRS. B. S. HALE & SON, Malden, Mass., and 16 Dey street, New York, manufacturers of insulated wires since 1857, announce in their price list No. 32, that they have added to their works facilities for winding magnets. They offer to wind bobbins to any desired resistance at prices very little in excess of the cost of the insulated wire.

THE SHAVER CORPORATION'S recent circular brings to mind the very considerable extent to which mechanical telephones are used for short lines. Mr. Shaver has given much time and energy to the development of his apparatus, and the corporation offer their telephones with much confidence and with many testimonials to their usefulness.

A LARGE BELT.—The Shultz Belting Co., of St. Louis, Mo., has just made and put into the plant of the East River Electric Light Co., New York city, one of the largest belts ever made in this country, and the largest ever made west of New York. It is 123 feet long, 58 inches wide and weighs 1,300 pounds. It is made of double leather, and is to transmit 1,000 h. p. The company made the belt, delivered it in New York, and had it transmitting power inside of six days.

This speaks well for the fulled leather (rawhide) belting made by this company. This belt was cemented only, no pegs or rivets being used at the joints.

MESSRS. CHAS. A. SCHIEREN & CO., say, "Information has reached us that attempts have been made to imitate our celebrated "electric" leather belting, and we take this opportunity to inform our patrons and the trade generally that we have the exclusive right to use the word "electric" as applied to leather belting. This right is granted us by registration in the Patent Office of the United States of America, dated November 17th, 1885, and numbered 12,785, and we hereby notify infringers that they will be prosecuted according to law.

THE NEW YORK STATE AGENCY, Sprague Electric Railway and Motor Co., has secured the services of Mr. C. H. Maclilie, of Chicago, Ill., to act as its representative in Eastern New York. Mr. Maclilie has had a large experience and has held important and responsible positions in the electrical field. Mr. Higgins is to be congratulated upon his success in securing, in so short a time, such an efficient and able staff of representatives.

OKONITE.—*The Electrical Review*, London, of June 9 last, contains a lengthy notice of this relatively new American insulating compound. After quoting the reports of several American electricians upon its properties, the writer says: "As regards the electrical and mechanical properties of "okonite," an exhaustive report by Dr. John Hopkinson, F. R. S., gives some information. The tests given by Dr. Hopkinson are remarkably good, but the results obtained by him are best given in his own words: 'Summary.—Shortly, my tests on these samples of Mr. Smith's insulated conductors prove that the insulation is practically perfect, both for high and low potentials, it is at least equal to the best G. P., and that the insulation will stand very rough handling, and a considerable temperature without injury, indeed, with a quite insignificant reduction of the insulation resistance.'" The article concludes as follows:—

"For ordinary telephone work we think that the inductive capacity and the amount of covering required are rather against the adoption of okonite, but for general telegraph work, especially for 'leading in' at stations, signal boxes, etc., this core will be specially valuable. Its mechanical properties, high insulation, and indifference to heat, render it a very efficient core for electric light purposes, and we should not be surprised to see it used largely for such positions and places where most insulated wires have hitherto proved failures."

THE BALL ELECTRIC LIGHT CO. (Limited), of Canada,—headquarters, Toronto, are introducing the Ball system in the British Provinces. They have recently issued a descriptive and illustrated circular, in which they lay special emphasis on their small arc lamps, called the "Ball subdivided arc light."

THE ELECTRIC WATER PROTECTIVE CO., 713 Broadway, New York, invite inspection of their protective system in operation at the above address,

MR. JARVIS B. EDSON'S last pressure recording gauge circular affords evidence of the large and widely extended use of his gauges. Fac-similes are given of many records obtained in actual service. The circular also includes instructions for the proper use of the recording gauges. Mr. Edson's devices were among the earliest in the class of practical apparatus for recording forces, consumption of material, and the like. When such records can be reliably made they seem scarcely less important in industrial work than records of wages or other money expenditure.

ELECTRIC STREET RAILWAYS IN AMERICA

Now in Operation.

ABBREVIATIONS.—**mi.**, miles of single track; **g.**, gauge; **lb.**, pounds rail per yard; **m.**, electric motors; **c.**, cars; **m. c.**, motor-cars; **h. p.**, horse-power; **T.**, T rail. Name of electric system used is in SMALL CAPITALS.

Notes.

THE BINGHAMTON, N. Y. electric road will soon receive additional electric outfit from the Thomson-Houston Electric Co.

THE SPRAGUE Co. has made a contract to supply electric plant to the Sandusky, O., street railway.

DENVER, COL.—The Short-Nesmith series electric road has been discontinued for some months. It is now being transformed into a cable road.

THE electric road, Richmond, Va., carried 17,108 passengers on the fourth of July last.

THE THOMSON-HOUSTON Co. has taken a contract for constructing a six mile electric road at Wichita, Kan.

THE OTTAWA ELECTRIC STREET RAILWAY Co. has been incorporated with a capital of $100,000.

THE HARTFORD AND WETHERSFIELD HORSE RAILROAD, Hartford, has been granted permission by the city council to use electricity as a motive power.

AT MERIDEN, CONN., the electric street railway is progressing favorably. Manager John L. Billard expects to have three cars running early this month.

BOSTON, MASS.—The Sprague Electric Railway & Motor Co, have closed a very important contract with the West End Railway Co., of Boston, Mass. The present equipment will consist of 12 miles of track and 20 cars, and everything is to be as complete as possible, in all details. Ornamental iron poles will be used.

PROFESSOR SIDNEY H. SHORT, formerly of Denver, Col., now of the firm of Sidney H. Short & Co., Columbus, Ohio, is following up his series system of electric street railways, adapting it to both conduit and overhead conductors. Mr. Short adopts and recommends the Brush dynamo for a generator.

THE HILL CLUTCH WORKS, Cleveland, O., whose clutch pulleys and couplings find favor in electric light stations, issue a very complete catalogue and price-list including plain pulleys, shafting, pillow-blocks, journal boxes, etc., with other information useful to the trade.

THE absurd deadlock that prevents the North and East River company from building its electric road in Fulton street still continues. The Bleecker street company still refuses to allow a short section of its track to be used in common, and nothing can be done without further legislation, the obtaining of which would consume months of delay, and has already been tried for in vain.

.... BARE electric wires could with safety be run through powder in bulk, and a heavy current transmitted, provided the conducting wires were large enough to carry the current and remain cool.—*Electrical Review*, New York.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From July 24 to August 14, 1888 (inclusive).

Alarms and Signals:—*Electrical Call System*, J. C. McLaughlin, 386,597. *Watchman's Electric Time Recorder*, G. F. Bulen, 386,767. *Electric Signal or Alarm*, E. Davis, 386,772, July 24. *Auxiliary Fire-Alarm Apparatus*, W. J. Dudley, 387,585, August 7. *Flash-Light Signal*, W. H. Thompson, 387,932, August 14.

Clocks:—*Electric Clock-Synchronizer*, A. G. Wiseman, 387,276, August 7. *Circuit-Closer for Electric Clocks*, C. D. Warner, 387,703. *Electric Clock System*, C. D. Warner and A. D. Bennett, 387,704. *Electric Clock-Synchronizing System*, C. J. Hexamer, 387,974, August 14.

Conductors, Insulators, Supports and Systems:—*Machine for Covering Wire*, W. H. Sawyer, 386,561, July 24. *Electrical Non-Conductor*, C. T. Lee and C. N. Waite, 386,925. *Electric Insulator Peg*, W. E. Joslin, 386,986, July 31. *Insulation for Mechanical Telephone Conductors*, F. E. Clark, 387,969, August 14.

Distribution:—*Method of Automatic Regulation for Electric Currents*, R. Belfield, 386,797. *System of Electrical Distribution*, M. M. M. Slattery, 386,936. *Regulator for Electric Circuits*, R. Belfield, 386,956. *Electric Converter*, O. B. Shallenberger and H. M. Byllesby, 387,013. *Apparatus for Electrical Conversion and Distribution*, W. Stanley, Jr., 387,117. *Flue for Electric Transformers*, E. Thomson, 387,123, July 31. *Electric Regulator*, J. A. Vansant and F. S. Anderson, 387,463. *Regulator for Electric Currents*, same, 387,464, August 7.

Dynamos and Motors:—*Dynamo and Motor*, C. E. L. Brown, 386,685. *Dynamo-Electric Machine*, W. Fritsche, 386,775, July 24. *Brush-Holder for Electric Machines*, A. Schmid, 387,010. *Regulator for Electric Motors*, A. G. Waterhouse, 387,194 and 387,195, July 31. *Dynamo-Electric Machine and Electric Motor*, R. E. B. Crompton, 387,343. *Armature for Dynamo-Electric Machines*, A. W. Meston, 387,432, August 7. *Electric Motor*, B. A. Fiske, 387,714. *Regulator for Dynamo-Electric Machines*, C. L. Buckingham and H. Lemp, 387,853, August 14.

Galvanic Batteries:—*Porous Cup for Electric Batteries*, B. J. Wheelock, and J. W. Wheelock, 386,569, July 24. *Battery Zinc*, R. L. Carr, 387,049, July 31. *Galvanic Battery*, E. M. Hewett, 387,642 and 387,643. *Jar for Galvanic Batteries*, B. Overlack, 387,654. *Electrolyte for Galvanic Batteries*, D. H. Fitch, 387,679. *Galvanic Battery*, G. T. Woods, 387,839, August 14.

Lamps and Appurtenances:—*Automatic Regulator for Electric Lamps*, R. Belfield, 386,796. *Storm-Protector for Electric Lamps*, T. H. Brady, 387,044, July 31. *System of Combined Arc and Incandescent Electric Lights*, H. P. Brown, 387,615, August 7.

Measurement:—*Inductometer*, G. Miot, 386,648, July 24. *Galvanometer*, P. Lange, 386,992 and 386,993, July 31. *Method of Measuring Electricity*, G. Forbes, 387,505, August 7. *Meter for Alternating Electric Currents*, O. B. Shallenberger, 388,003. *Method of Measuring Alternating Electric Currents*, same, 388,004, August 14.

Medical and Surgical:—*Electro-Medical Apparatus*, J. S. Muir, 386,754, July 24.

Metallurgical:—*Amalgamator*. A. H. Eysaman, 387,347, August 7.

Miscellaneous:—*Electric Valve Controller*, E. Grah, 386,463. *Electric Governor*, H. W. Parsons and J. Hodult, 386,602. *Latch-Opener for Knitting Machines*, L. Jones, Jr., 386,636. *Electrical Type-Writer*, J. F. McLaughlin, 386,646. *Coin-Operated Induction-Coil*, P. G. Williams and A. W. Roovers, re-issue, 10,949, July 24. *Temperature Regulator*, C. W. Johnson, 386,828. *Coin-Operated Induction-Coil*, P. G. Williams and A. W. Roovers, 386,860. *Coin-Operated Electrical Apparatus*, P. Everitt, 386,919. *Lightning Arrester for Electric Circuits*, F. A. Cheney, 387,051. *Electric Indicator*, W. A. Anthony, 387,131. *Galvanic Boiler-Cleaning Compound*, F. J. Clamer, 387,145 and 387,146. *Electric Rock-Drill*, G. Guntz, 387,160, July 31. *Electro-Mechanical Movement*, R. H. Mather, 387,310. *Electric Switch-Lock*, E. L. Orcutt, 387,36 . *Electric Switch*, J. F. McElroy, 387,526, August 7. *Electric Cut-Out*, J. A. Powers, 387,732. *Automatic Coin-Operated Ticket Printing Weighing Scale*, E. E. Amet, 387,842. *Process of Preparing Aluminum Bronze and other Alloys*, P. Heroult, 387,876, August 14.

Railways and Appliances:—*Railway-Car*, E. Verstraete, 386,512. *Railway Signal Circuit Breaker*, E. B. Ives, 386,541. *Compound Electromotor for Electric Railway*, A. J. Jarman, 386,543. *Current-Receiver for Electric Railway Cars*, J. A. Enos, 38 ,581. *Overhead Wire Connection for Electric Railways*, W. H. Knight, 386,784, July 24. *Railway Signaling System*, E. L. Orcutt, 387,316. *Electric Railway System*, D. G. Weems, 387,382 and 387,383. *Electrically-Driven Car*, J. Weis, 387,610, August 7. *Motor for Railway Cars*, W. M. McDougall, 387,726, August 14.

Storage Batteries:—*Storage Battery*, J. A. Enos, 386,580, July 24. *Secondary Battery*, J. S. Sellon, 386,898, July 31. *Apparatus for Charging and Discharging Secondary Batteries*, M. Pfatischer, 387,988, August 14.

Telegraphs:—*Telegraph Key*, L. Townsend and J. E. Auten, 386,729, July 24. *Art of Telegraphy*, E. Gray, 386,814. *Telautograph*, same, 386,815, July 31.

Telephones, Systems and Apparatus:—*Multiple Switch-Board*, M. G. Kellogg, 386,886 and 386,887. *Telephone Transmitter*, W. R. Cole, 386,965. *Phonograph*, T. A. Edison, 386,974. *Mechanical Telephone*, A. W. Hall, 386,980, July 31. *Mechanical Telephone*, M. Carl, 387,636. *Multiple Switch-Board*, M. G. Kellogg, 387,645, 387,888, 387,889 and 387,890. *Telephone Support*, N. W. Hartwell, 387,718, August 14.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. VII. EXTRA—SEPTEMBER 15, 1888.

PROCEEDINGS OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION AT THE FOURTH SEMI-ANNUAL CONVENTION (EIGHTH MEETING), HELD AT NEW YORK, AUGUST 29, 30 AND 31, 1888.

FIRST DAY'S PROCEEDINGS—WEDNESDAY, AUGUST, 29.

THE convention was called to order at 12 M. at the Hotel Brunswick, on August 29, by the president of the association, Mr. S. A. Duncan, of Pittsburgh, Pa.

The president addressed the convention as follows :—

PRESIDENT'S ADDRESS.

Gentlemen of the National Electric Light Association in convention assembled:—

WHEN this association, after six months of existence, last met in this great city of New York three years ago, but sixty gentlemen were present. To-day we are over three hundred, in other words, the attendance has increased five-fold. I am, therefore, able to congratulate you upon the growth, prosperity and stability of this organization, in whose welfare we are all so deeply interested, and in whose commercial usefulness we all take pride ; for we all had a hand in its making. And I am also able to congratulate you upon that which is more important than numbers, and that is the fact that this association is rapidly becoming the centre of all matters pertaining to the arts which depend on the application of powerful electric currents, and that its proceedings are watched with growing interest not only by the whole electrical public of this country, but also abroad. It is sometimes interesting to notice how we are regarded beyond those limits which properly come within our jurisdiction; and I would call your attention to a fact, which is certainly not uncomplimentary, and it is this :—although during the early days of our history the technical papers abroad paid no further attention to our proceedings than to ridicule them, yet of late, and more noticeably for the last six months, almost every paper which has been read before this association has been copied by the leading electrical papers all over the world. And can there be a better indication of the growth of the industries which have been fostered by this association than the fact that they support in this country no less than eight journals devoted exclusively to electrical matters? This prosperity, upon which we have been mutually congratulating ourselves, has been due not only to the commendable efforts of the rank and file of our membership, but also, in no small degree, to the good judgment, perseverance, untiring energy and marked ability of our honored past-president, Mr. J. F. Morrisson, and the able committees which have assisted him in administering the affairs of the association.

But it is of more importance to us to consider the present state of the industry. From time to time statistics as to the amount of electric light apparatus in use in this country have been presented to the association. At Pittsburgh it was estimated that there were no less than 4,000 isolated plants, and central stations operating 175,000 arc lights and 1,750,000 incandescent lights. To these figures we may now add that there are 1,351 new isolated plants and central stations operating 35,201 arc lights and 392,944 incandescent lights, of which I have a detailed record. By adding this increase to the figures of six months ago, we find there are now 5,351 isolated plants and central stations, and there are burning every night in the year in the United States no less than 192,500 arc lights and 1,925,000 incandescent lights. We may also add that there are 459,495 h. p. of steam engines devoted to electric lighting. Figuring this in coal consumption, it can be demonstrated that, in the year 1888, enough coal will be consumed in the United States for electric lighting purposes to make a solid column one hundred feet square and over a mile high. It may be here parenthetically remarked that there has been an increase in the capitalization of the electric light companies of the United States in the last six months of not less than $42,210,100.

But we have not yet touched upon the great industry of the electrical distribution of power. There are, at the present time thirty-four electric railways (of which I have a record), completed and in operation in the United States, having an aggregate of 138 miles of single track, and operating 223 motor cars and utilizing 4,180 h. p. in stationary engines. There are, also, now in process of construction 49 other electric railways, aggregating 189 miles of single track, which will operate 244 motor cars; thus at the present time there are constructed and being constructed 83 electric railroads aggregating 327 miles of single track and operating 467 motor cars. In this connection it must be remembered that there are 39 other electric railroads incorporated which have not yet begun construction. It is also estimated that the electric cars now in operation in the United States will carry in the year 1888 no less than 17,045,500 passengers. It can be better imagined than estimated what will be the ultimate outcome of an industry which has arrived to such a degree of development in three years.

In view of the difficulty of compiling statistics on such small unities, it has been impossible to collect reliable information relative to the stationary motor business, but we know that at the present time it has stimulated capital to such an extent that there are single factories employing no less than 1,500 hands each in the manufacture of electric motors, and, at no far distant day, all large cities will have their power stations of several thousands of horse-power each, distributing energy throughout every ramification of industry. So rapid a development of this new industry into gigantic commercial proportions should be an admonition to the electric light companies now in the field to reap the harvest which is white to their sickle, and not to wait for competitors to come within their field of operation in the shape of power stations; for power companies, once established, will reach out and take in a large portion of the electric lighting business.

The present meeting of this association gives promise of being one of the most interesting so far held. The report of the secretary and treasurer shows the association to be in a gratifying financial condition, there being a balance

of a thousand dollars in the treasury after the payment of all bills, and the membership is steadily increasing. The proceedings of the last four conventions have been printed and furnished with a thorough cross index, and each member has been provided with a copy. The admirable way in which the proceedings have been printed reflects credit upon the executive committee, under whose direction it has been carried out, and the carefully compiled cross index, and the accurate technical proof reading of the publishers of "Modern Light and Heat" deserve creditable mention. The report of the executive committee, through its chairman, Dr. Otto A. Moses, and the reports of the several committees, together with the papers to follow, should command the closest attention of the entire convention.

The difficulty of obtaining reliable statistical information in regard to the various electrical industries, and thus keeping up a continuity in the work of the association from one convention to another, warrants the president in urging upon the association the necessity of establishing a permanent office which shall be a repository of all information relative to the allied electrical industries, and a means of intercommunication between its members, and from which the officers and executive committee can administer the affairs of the association. This office should contain a good reference library of electrical works, complete files of all domestic and foreign electrical and other technical journals, and be the repository of the archives of the association. It should be a place where every member of the association could feel at home, and where he would naturally go for any electrical or other information that it contained. A very slight increase in the running expenses of the association would maintain such an office, and when established it would, from its innate value, increase the membership of the association to such an extent that the running expenses of such an office would take care of themselves.

Does not this association, having, during its years of growth, spread its roots widely through the electrical industry of this country, stand upon the eve of becoming much more widely influential than ever before by carrying out the suggestion of Mr. Frank Ridlon, at the convention in this city three years ago, which was further elaborated by a committee specially appointed for that purpose, which reported, through its chairman, Dr. Otto A. Moses, at the Detroit convention, and was still further advocated by Mr. Arthur Steuart, Mr. E. R. Weeks, Mr. A. J. DeCamp, at subsequent conventions—namely, the establishment of a permanent headquarters as already sketched out?

Gentlemen, in conclusion, I will say that in no way can you better assist the chair in the discharge of his duties, and in no way can you aid in making this convention a thoroughly successful one, than by a constant attendance at its sessions. I know that the more than generous hospitality in the shape of various entertainments, as mapped out by our New York friends, may tend somewhat to distract your minds from the serious business for which you have assembled, but I also know that you can find ample time, not only to accept of their hospitality, but to give to this convention your entire time and attention during its sessions.

Gentlemen, it affords me great pleasure to have with us this morning a gentleman of national reputation, with whose name you are all familiar. I have the honor of introducing the Hon. Abram S. Hewitt, Mayor of the City of New York. (Applause.)

His Honor, the mayor, then addressed the convention :—

ADDRESS BY HON. ABRAM S. HEWITT, MAYOR OF NEW YORK.

Mr. President and Gentlemen of the Convention:—

My duty on this occasion is as easy as it is agreeable. I am here to bid you welcome to the City of New York, and to tender you such hospitality as the mayor of this city has it in his power to offer. To distinguish strangers, I think the usual form is to give the Freedom of the City in a Gold Box. If you will leave out the Gold Box I can tender you the Freedom of the City, but exactly what it is I do not know. (Laughter.) But to those who are strangers here I trust it will be found exceedingly pleasant and highly profitable.

I gather from the remarks of your president that you are here to take an account of stock of what you know about electrical science and its application to useful purposes. I think it will be easier for you to ascertain how much you do not know than to find out how much you do know about this subject. (Laughter and applause.) And in the last part of that inquiry I am in entire sympathy with you. When I have confessed, as I have had to do on various occasions, that I did not know anything about this subject, it has been received with incredulity, but you who do know something about it know that I am exactly right. When you reflect upon what you have to do you must be rather appalled at the magnitude of the contract. This convention must strike the average uninstructed mind pretty much as a meeting of astrologers in the ante-Christian era would have done throughout the orient, or a convention of necromancers and magicians during the Middle Ages. You deal with something very mysterious to the popular mind, almost incredible. You have already performed wonders which even to the most intelligent men can only be regarded as miraculous. You stand to-day pretty nearly in the condition in which Watt, 110 years ago, must have found himself when he produced the first perfected condensing engine. Crude forms of engines had been in use doing more or less effective work prior to his day; but in 1776, the year of our emancipation from foreign control, Watt produced the first real working machine. Now, what has been done in 110 years. Could any man if he had been gifted with the power of prophecy—could any man have foreseen the transformation which the whole world would undergo in a century from the time of that great invention? Can you conceive of the world without a steam engine? Could the population which now inhabits the globe survive for 60 days if the steam engine were withdrawn from use? Would civilization continue in existence to-day without the steam engine? Now, gentlemen, looking back you can see how the application of one great motive force can transform the face of the world. Looking forward, is there a man here who can tell us what this new electrical force is going to do for the world? Can any man say how it is to be enriched, how it is to be purified, how it is to be exalted from the depths of poverty and suffering into which in large part it is plunged? If electricity, like air and water, could be made free to the hand of labor or to the wants of men, could be on tap, so to speak, either without charge or at a merely nominal cost, do you not see that all monopoly would cease to exist? For monopoly consists in nothing but the power to appropriate force to personal and private use. If all force and all power were made free to all men, is it not apparent that the inequalities of fortune and almost all the evils of which mankind complain would disappear? Is there anything more astonishing in this prospect than in the retrospect, which you can all take, of the work that has followed the introduction of the steam engine? I used to be told when I was at school—I don't know how it is now—that the earth is a great magnet. You may have changed all that, but I hope you have not for I do not want to lose what little I do know. (Laughter.) We used to be told it was a great magnet, and that it revolved on its axis once in 24 hours, and that it was 25,000 miles in circumference. Now, that strikes me as the definition of a mighty large dynamo. If a great magnet 25,000 miles in circumference is put in revolution so as to turn on its axis once in 24 hours, from what I have seen of the dynamo it strikes me that there must be a vast incalculable fund of electricity produced by that operation. (Applause.) I know nothing about it, I may be talking nonsense; but at the same time, if that be true, and if it be true of the whole planetary system, and

of the whole universe of the Divine Architect, what a vast fund of unappropriated power there is for mankind in the future; and knowledge is power and power is wealth, and wealth, which is free to all who have the brains to take it, is the benefaction of mankind and the opening of the gates of the millenium, if we are ever to see it, it will be accomplished by you gentlemen and those who will come after you, for this is the only course that I am able to see by which the goodness of God, the bounties of Divine Providence can be distributed with a free hand to all the world, and to every man, woman and child within its bounds. (Applause.)

Upon the borders of this land of dreams we stand. You are slowly raising the curtain of the future. I shall not see the drama played to the end; but there are men in this room who will live to see society transformed by this new agency; for it is a curious and suggestive fact that all moral forces and all moral questions find their final resolution in the facts and laws of physical nature. There is where you come at last. If this world is a better world to-day, a richer, a happier, a more enlightened world to-day than it was a hundred years ago, it is due mostly to the steam engine and its applications. If it is to be, as I believe it is to be, a better world, year by year and century by century, it will be due to the discoveries and applications of electrical force, or of some other force which possibly may be hereafter discovered and developed; but to-day we must call it by the name which you and I know it by—the electrical force.

Hence I bid you welcome to New York. I am glad to see you. You are benefactors. You come to two millions of people with a gospel. You are the apostles of a new industrial dispensation. You are distributors of this overgrown wealth which you hear is in few hands in this great city. It cannot stand your attacks. It has withstood the preacher and the moralist and the philosopher; but it will not stand against the scientist who discovers the laws of nature and who makes them free to all who will drink at the fountain of science. (Applause.) Yes, you will revolutionize the world; you will regenerate society; and it is none the less to your credit that while you are doing it you are making your living and getting an honest compensation for your labor; for it is a law of Divine Providence that utility and beneficence shall march hand in hand down the highways of civilization. They are bound together by a divine law, and you are the executors of that law when you open new fields of discovery, and new applications of force to useful purposes. Of course we bid you welcome, and we bid you welcome because we feel that we are so ignorant and need your help. We are engaged in this city in undertakings which require from you your honest and best judgment. We send messages by wire through our streets. We light them through conductors perched upon poles. We talk through a network of wires so thick overhead that often the sky is obscured. They are not pleasant to look at, but they are indispensable, in the present state of knowledge, to the business of society. (Applause.) The man who would disturb them until something better is found out and proved to be found out, would be a barbarian. (Applause.) Still, like the mayor, they have got to go. (Laughter.) But the mayor is too old to go at a 2.40 gait, and he likes to see his way clear before he takes a step. Now, in order to clear up this matter a little for you who know so little, as I have said, about this subject, and I, knowing so much, let me say that this much seems to have been found out at some cost to somebody. I do not know who—that it is quite feasible to put underground all the telephonic and telegraphic wires, and in fact all wires which carry low tension currents. I suppose that is now demonstrated, and I trust that in a very short time this city will be relieved from the unsightly telegraphic wires, telephonic conductors and from any modes of diffusion for the incandescent lighting which may still remain above ground. I suppose that is all feasible. The question what to do with the high tension currents remains. First, we ask you to tell us—at least I ask you to tell me, because there are some people here who know better than I do—whether a satisfactory mode of cable transmission for high tension currents underground has yet been devised. I understand that a cable for the Brush company is about to be laid in one of the conduits which have been constructed in Broadway, and I suppose that will test the question as to the feasibility of the transmission of high tension currents practically and economically, because there is no sense, you know, in things that don't pay; if it is too dear we have got to give it up. (Applause.) I suppose that that will test the question, and I am very glad of it. I have been censured—possibly by you electrical gentlemen; I do not know—very much, for not having taken steps to coerce all these lighting companies into putting cables underground until that question was settled.

Well, I am no longer a young man. I have had a long experience in life. I have done a pretty large business in my time. I have had to deal with very difficult problems, and I have learned that the part of wisdom is to go slowly and to ascertain your facts and get your knowledge before you undertake to reconstruct the universe. I have been very desirous that this matter should be tested —this question of transmission of high tension current underground—at the earliest possible moment, and I congratulate you on the fact that it is going to be tested by a responsible company, and until it is tested, let me say to you frankly that if it were in my power to compel the other companies to do this thing now to-day, I would not do it. (Applause.) I should look upon myself as an everlasting fool who ought to be consigned to seclusion in a madhouse if I did such a thing. But I hope it will succeed, and if it does succeed no public officer will be more prompt than I shall be in compelling every electric light company to respect the intention of the legislature when it confided this great work to four men who did not know anything about what they were going to do. (Applause.) The legislature evidently recognized the fact, which you recognize and I do, that what we don't know about electricity is a good deal more than what we do know about it, and so, as they could not find men who knew about electricity, they *did* find some men who were supposed to understand politics if they did not know anything else. I speak thus frankly, because I am one of the four men. (Laughter and applause.) I should be the last man to cast any imputations upon my colleagues who have charge of this most interesting and important public work; but I think that we shall all of us be wiser—my colleagues as well as myself—after a little more experience has been gained.

Now the second question is this: When the cable is underground and works successfully, will you kindly inform me and the public, in whose behalf I address you, whether a satisfactory system of distribution from the conduits has been discovered and put in practice? It is one thing to put the current underground and another thing to get it out so that there may be lights. Now, I know nothing about it; I have simply made inquiries of every intelligent electrician that I could meet, and up to this time I have not been able to ascertain that there is a satisfactory mode of distribution. Now you know whether there is or not. If you should say to me, after a discussion of the subject that there is, I should accept your judgment as final, because you embody all that there is known of this difficult subject, and if you, by your resolution, say that there is a proper and comprehensive system of distribution so that the evils that are complained of will be abated and that there will be absolute safety in the distribution, then my mouth will be closed, and I shall act upon your judgment; and that is the reason why I have come here, chiefly to-day, not simply to welcome you as strangers and guests from abroad, but to ask you to consider this subject coolly, dispassionately, intelligently, and give us the results of

your discussion, so that we may act coolly, dispassionately and intelligently in carrying out the law.

Now as to the matter of danger. The newspapers have teemed during the last year with sensational articles pointing out the great danger of the present system. Remember I do not like the present system. I regard it as—I was going to say—barbarous. The streets should not be defaced. We should not have these wires running about. But let us get at it on proper grounds—æsthetic grounds, if you will, scientific grounds, economical grounds—any other grounds than prejudice and sensation. Those I take no stock in, and I will never allow myself, and I trust no man who is a lover of truth will allow himself to be dragooned by the newspapers into doing what he believes to be wrong. Now, is this dangerous, will you kindly tell us? I thought it was exceedingly dangerous; I went into office with the impression that every man who went out in a street lighted by a high tension current took his life in his hands, and I was as anxious as anybody to get the wires removed; but when it became my duty to look into the matter, I found that in proportion to the amount of work done, measured by our friend the president's column of coal, if you like, or by those other things that you call ohms and volts, and which my colleagues of the board of electrical control are flinging at the common council pretty much as that distinguished millionaire at Saratoga turned out his gems among the boys the other day—(laughter)—I found, measuring this industrial element, call it what you like—some name you must call it—this force, this power, measuring it by the work it was doing, and ascertaining the accidents that occurred, to my astonishment I found that we had more accidents daily from the horses in the streets—infinitely more; that we had more accidents with steam engines; that even the building of houses in the city caused more deaths every year—infinitely more deaths in this city than this particular agency. I was therefore driven to the conclusion that considering the work it was doing, comparing it, if you like with the illumination by gas, that it was positively safer, just as the railway had proved to be safer than the stage coach and the stage coach probably safer than walking, for the number of people carried. I found that with all the difficulties with this thing, the absolute results seemed to show that it was absolutely safer than any other useful agency at work in this city. That was the conclusion to which I was forced. But then, when I investigated the cause of the accidents, I discovered that they were not due to anything that was inherent in the transmission of the current overhead; but they were rather due to two causes—either the carelessness of the company in inspecting its installation, and keeping it in good order, or in the carelessness of the person who came in contact with it—one or the other. Now there is no excuse for the company, not the slightest. They undertake to render a public benefit; they are paid for it; they undoubtedly ought to see that their plant is in the most perfect order possible, and any company that neglects to keep its plant in proper order is, of course, liable to the penalties of the law, and I would be the first to have the officers of such a company indicted, if I could. But I take it that the duty has been on the whole pretty well performed, because the accidents have been so few. They have been very few indeed. I believe that in this city there are but four cases of death in consequence of any difficulties with the wires themselves. I may be in error. It is either four or seven, but I believe it is four. Now, under the circumstances, the thing that would seem to be wanted—and I think it will be wanted when you come to your plan of distribution just as much as it is wanted now—is a thorough inspection of the means by which the light is made available to the public above the ground, and that inspection should in the first place be made by the companies themselves, who have the greatest interest in the matter and the largest duty to perform, and I fully agree that the public, who have a great interest in it, should also have a thorough inspection, and the reasonable rules and regulations which may be adopted by the body that is charged with the custody of this matter should be implicitly obeyed, and any violation of them ought to be severely punished. But I would like you to consider the whole question, not merely the distribution; but if you come to the conclusion that no adequate mode of distribution has been found which will dispense with the present mode, then, that you will consider and advise us how we can make it safer to the public, and thereby more economical and useful to the companies who supply the lights. These are questions of such paramount interest in this city that your presence here is most welcome. I trust you will give us the benefit of your knowledge, and when you do not know I hope you will say so and confess your ignorance like men, for that is what I have now been doing, and what I intend to do so long as I am mayor. Gentlemen, you are welcome to New York. (Applause.)

The President—Your Honor: in accepting on behalf of the association the freedom of the City of New York, I desire to confess that, like yourself, I do not know what it is, but I may state to your Honor that in whatever city we have been the association have practically taken control of the city for the time they have been in it.

In regard to the considerationof the points brought forward by his Honor in his address I desire to say that this whole question will be considered to-morrow morning at 10 o'clock, when we shall be very glad to have his Honor present with us. We have already extended an invitation to the members of the subway commission and others who are interested in this matter, and we are seeking for all the light we can obtain on this subject. We have come to consider this matter calmly, coolly and dispassionately, not only for the interest of the public at large, but for the interests of the electric lighting companies, and I can assure you, sir, that we will consider the subject in the spirit which you have suggested.

I now declare this convention open for the transaction of such business as may be brought before us.

The first business in order is the report of the secretary and treasurer.

Mr. W. H. Harding, secretary and treasurer, then read his reports. The secretary's report showed a membership of 189, over three times the number of original members.

Mr. Harding's report as treasurer was as follows:—

TREASURER'S REPORT.

BALTIMORE, August 25, 1888.

Report of the Treasurer of the National Electric Light Association.

Feb. 18, 1888.	To Balance....................	$ 971.67
	Dues received from February 19, to Aug. 25....................	1,480.00
	Contributed from Westinghouse companies at Pittsburgh......	1,150.00
	Contribution from Chas. Schieren, N. Y........................	50.00
		$3,651.67
	Disbursements.	
	As per detailed report..........	1,716.44
		$1,935.23

The reports of the secretary and treasurer were received, and ordered to be filed and printed.

The secretary read a letter from Mr. George Worthington, Editor of the *Electrical Review*, inviting the members of the association to visit the "Fall of Rome," at Staten Island in the evening; an invitation from Mr. Theodore Moss to attend a performance at the Star theatre, an invitation from the Okonite Company to attend a performance at the New Broadway theatre Thursday evening, and an invitation from the Electric Club to all the members to visit the club house during their stay in the city.

On motion of Mr. C. A. Brown, of Chicago, it was voted that a committee of five be appointed by the chair to select the place for the next meeting of the association and to report to this convention.

The President—We will proceed with the order of business, and take up the report of the committee on the testimonial to Mr. J. Frank Morrison, of which Mr. T. C. Martin is the chairman.

Mr. T. C. Martin—Mr. President and gentlemen: in accordance with the resolution adopted at the Pittsburgh meeting, the resolutions there passed with regard to the services of Mr. J. Frank Morrison to the association have been engrossed. I have the resolutions in my hand and I believe that it would be in keeping with the wish of the meeting if before the presentation of the engrossed resolutions, they be read. They are as follows:—

"*Whereas*, it has pleased Mr. J. Frank S. Morrison to insist upon

not being re-elected to the position of president of the National Electric Light Association, which he has continuously held since its organization; and whereas, we have tacitly agreed at our successive re-elections of him to allow him to retire (as he has invariably requested at each meeting) whenever the interests of the association would not suffer by such action; therefore, be it

"*Resolved*, That we, the National Electric Light Association of America, representing in our midst every department of electric light and power industry, express our deep regret at the decision of Mr. Morrison not to allow us to keep him at the helm, where, through many storms and quicksands, through much fair weather and some foul, he has successfully guided us to the haven where we now find ourselves; and be it further

"*Resolved*, That a vote of thanks be given Mr. Morrison for the disinterested devotion, enthusiasm and steadiness with which he has administered the affairs and presided over the proceedings of our conventions; and that, further, we tender him our best wishes for his deserved enjoyment through a long and prosperous life, of the beautiful prospect of the great work he has done in founding, fostering and chartering the National Electric Light Association."

Such, Mr. Chairman, were the resolutions, and there (presenting the engrossed and bound resolutions) is the result of our work. Mr. Morrison, I have the greatest pleasure, in the name of the association, in tendering you the engrossed resolutions which have just been read. (Applause.)

Mr. Morrison—This is perhaps the first occasion since my acquaintance—my intimate acquaintance—with the gentlemen who compose the National Electric Light Association when I have been glad that I am not very well. I find, at this very agreeable surprise party which you have prepared for me—and it is a wonder it has been kept quiet when so many men knew it—that I am almost unable to talk, and you know what a terrible thing that is to me. I accept the gift which you have presented, and I think it is needless for me to say to you, and I think you will believe me when I say, that I fully appreciate the spirit in which it is tendered. At the start this association required, perhaps, different material in its presiding officer from that which it requires to-day. I believe that for the first year I filled the bill fairly well. I do not flatter myself very much. I believe that after the first year a man more yielding and conciliatory than I am would perhaps have filled the bill better. Through your kindness and indulgence I was continued in that honorable office until last February, when you kindly permitted me to retire. For that and the beautifully engrossed resolutions expressed in such kindly terms I now thank you. I am not out of the service by any means. I hold the honorable position of a member of the executive committee, and I do not propose to be a deadhead in that or any other part of this enterprise. I am at your service now, gentlemen, as I was before, and I expect to remain in the service so long as the National Electric Light Association exists and I live. I thank you for the compliment. (Applause.)

The president then called for the report of the executive committee. The chairman, Dr. Otto A. Moses, reported verbally, as follows:—

REPORT OF THE EXECUTIVE COMMITTEE.

At a meeting this morning of the executive committee, preparatory to the beginning of our exercises, I announced that owing to the pressure of circumstances and the numerous arrangements that had to be made, I had not been able to prepare a report of the executive committee. A gentleman who has just left here said that sometimes in weakness there may be strength, meaning by that that having no report to make perhaps I might get over it quicker than I might otherwise do. The facts are, we have been doing as Doctor Arnold did when he said "A teacher is a man who is striving all the time to make himself useless." The executive committee of this association has striven so far to become a vanishing point, a zero at this moment, and now the convention has taken the matter into its own hands and the executive committee has disappeared below the surface Our only function was that which is generally given to executive committees, to arrange matters, to bring them into some kind of shape, and chance has a great deal to do with the forming of that shape. Gentlemen, the executive committee has no report to make beyond this, that they deem themselves exceedingly fortunate that the turn of events has allowed the mayor of the city to-day to open up so beautiful a field as he has done. Our business largely shapes itself, and the discussion that will take place to-morrow will be one of great local importance here, and will give zest, I hope, to the entertainments that you will receive of both an intellectual and a physical character.

The report of the committee on revision of the constitution of the association, was then presented by Mr. A. F. Mason, chairman, and was read by the secretary.

Printed copies of the report, ordered by the committee, not having yet come to hand for use of the members in considering amendments, it was voted to defer action on the report till Thursday, making it the first order of business for the afternoon session. [See proceedings and constitution as amended in Thursday afternoon's proceedings.]

The president then called for the report of the committee on insulation and installation of plants.

REPORT OF COMMITTEE ON INSULATION AND INSTALLATION.

Dr. Moses—Gentlemen, I appear here on behalf of the chairman of the committee on insulation and installation, Professor Elihu Thomson being the chairman. I received the following letter from him which causes me to speak for him:—

Lynn, Mass., Aug. 25, 1888.

DR. OTTO A. MOSES,
Hotel Brunswick, New York.

Dear Sir:—It will be impossible for me to make any formal report of the work done by the committee on insulation and installation of plant.

If you will prepare a brief statement of what was done at the meeting and attach the enclosed schedule of data to be asked for, I think that it will be all that can be done under the circumstances. This might be presented as an informal statement of what was being undertaken by the committee, and the association might then be called upon for the preparation or printing of a number of such blank schedules to be sent to the various electric light companies.

The spacing in the schedule will need to be modified so as to give more room in some places and less in others for the answers to the questions.

I am hoping to be able to run down to the meeting, but I may not be there at the time when the report may be in order, and will therefore look to you, if present, to say what you can of the progress made.

Some time ago I sent a copy of the schedule to each member of the committee, but have thus far received but two acknowledgements. Yours truly, ELIHU THOMSON.

Gentlemen, I stood last year in the position of apologizing for the action of this committee, and it was a most unfortunate position that I was put in, because I had been somewhat instrumental in organizing it. Everybody, however, was so much occupied with the rush and push of these matters that it was impossible to get what ought to have been obtained with the amount of talent that I was able to suggest should be put upon that committee. I was put upon it involuntarily, gentlemen. However, the committee has met, it has done work, and here you will find it embodied in a series of questions. But like a great deal of work that is contained in a very small space you will find that it does not show to any very great advantage. This schedule referred to here is for the purpose of obtaining data on the insulation of wires. There are 99 questions in it. Gentlemen, I would say there were a hundred, but you know the old story. There are just 99 questions and they will all be submitted to you in due time. I hope that you will all reply to them very carefully so as to give us data or our successors data to produce some valuable information for this association. These questions go to the very root of the life, use, advisability of employing conductors of all kinds. It is divided into various heads, and if you will only each of you write a small book—because to answer these questions means to write a small book to this association, we will have a library of our own that will come out of the actual experience of the members of this association. None of the members of the committee have written papers on the subject. We have had several meetings. These questions are the result of conference on the subject. However, to-morrow on the occasion of the underground discussion you will hear a very important paper read by the only member of the committee who did not feel himself justified in serving—that was Mr. Acheson, of Pittsburgh. It was the only compliment he was able to return to the association for the honor they had done him in electing him a member of the committee, although he was an interested party. It was a high compliment, and he shows his appreciation of it by reading a paper on the disruptive discharge in underground currents. It was hoped by the president in appointing this committee that each member would take a branch in a scientific direction in the solution of this question. Mr. Acheson has set a good example. I must admit that I tried to have the committee take that general direction, but failed of success from want of leisure which brings many a man to do things that he would not otherwise do, because they were all disposed to write scientific articles, but they were compelled to embody as much as they could in these questions throwing on you the onus of answering what you would answer.

That is the report I would offer for the chairman who is absent. He may come in the course of the day after I have received the brunt of all your criticisms. But I must say it is not my fault; I must say that in self-justification. So far as your position in this matter is concerned, all you have to do is to appoint another committee, if it is thought desirable to continue the subject, and step by step to gather such information as can be obtained by answering these questions. It will take a great deal of labor to collate the information which will be gained when this paper is distributed through the whole country.

Dr. Moses read the schedule submitted by the committee, which is as follows:

DATA ON INSULATION OF WIRES.

Name of company.
Location.
Name of superintendent or person having charge of lines and machinery.
How long has he been in charge?
Character of plant. Arc? Incandescent?
Systems in use. Dynamos. Lamps.
How long is line (miles or feet).
What wire or wires have you used and found unsatisfactory?
For what purpose used, and the defects found.
Do you use extra insulation on portions of wire exposed to moisture or abrasion?
If several kinds of wire are used please fill out enclosed blanks, one for each kind of wire.

OVERHEAD WIRES

Name of wire.
Maker's name and location.
When purchased?
How long in use by you?
Material of wire (copper)?
Diameter of metal, or gauge number (B. & S.).
Diameter over covering.
Weight to the mile.
Stranded or solid wire, *i. e.* flexible cable of a number of wires or not?
Furnish, if possible, a small sample, say five inches, and send by mail with a tag attached.
How supported?
What kind of insulators?
If more than one kind please state specifically
Condition of installation with respect too ther wires, as telephone, telegraph and other electric light wires.
Are crosses liable to happen from such other wire?
Condition as to running through trees, etc.
Are grounds liable to happen from this cause?
In arc wiring please say whether all or a part only of the lines are exposed to crosses and grounds.
Are the lines, pole lines or housetop lines, or both?
Have you had trouble from abrasion, or loss of covering from any cause?
At what point between poles is deterioration most likely to occur?
Prevailing or average climatic condition in your locality as to heat or cold, moisture or dryness, etc.
Add other conditions, such as exposure to deposits of soot, exposure to steam or other vapors.
Character of current, alternating or continuous?
Potential of lines.
How many lamps in series (if arc) and what type?
If incandescent wire, what voltage between mains?
If mixed incandescent and arc on this wire, state what capacity dynamo is used on line.
Have you had many leaks by grounds or crosses on this particular wire?
To what cause do you attribute them?
What is your experience with this wire generally? Here state how you regard it as a covered wire, good or the reverse, with whatever remarks you wish to make.
How much of it have you in use?
Are you installing with this wire new extensions of your lines?

INSIDE WIRING.

Name of wire.
Maker's name.
When purchased?
How long in use?
Material, copper.
Range of diameters or gauge (B. & S.).
Heavy or light covering?
Flexible cable or solid wire?
Furnish specimens, say five inches long, carefully tag same, and send by mail.
How supported? cleats, porcelain knobs, moulding, pipe, etc.
Concealed or not?
If a variety, name them.
Character of buildings wired with this particular wire; stores, manufactories, dwellings, etc.
Is any such wiring exposed to damp acid fumes or extreme heat?
Current used, alternating or continuous?
If arc wire, how many and what kind of lamps in series, or what capacity of dynamo?
If incandescent wire, what potential or voltage on lamps or between mains?
If mixed incandescent and arc, please describe the manner of use.
How has the wire stood in use, any faults developed?
Is it fire-proof in your estimation in the sense that it will not carry fire as a wick?
What is your experience and estimate of this wire generally, with whatever remarks are pertinent to it?
How much of this wire have you in use?

UNDERGROUND WIRE.

Name of wire
Maker's name and location.
When purchased?
How long in use by you
Material, copper?
Diameter of metal or gauge (B. & S.).
Diameter of covering.
Armored, lead, covered or not?
Compound or single wire cable, one or more wires in sheath.
Furnish, if possible, a small sample, say five inches, send by mail with tag attached.
How placed and supported, what kind or kinds of conduit, if any, are used?
Are other wires laid alongside either in the same conduit, or parallel in the same soil?
State the character of the soil surrounding the conduit or wires, wet, moist or dry.
How are lateral connections made from the conduits or wires to buildings?
Is there any exposure to escapes of gas as sewer gas or illuminating gas?
If lead covered, does the lead show in any place progressive corrosion?
What are the faults found in your underground wires?
To what cause or causes do you attribute such faults?
Are your underground wires used for arc light works or series work with high potentials?
Are they used with incandescent direct currents and low potentials? or for power lines?
Are such wires used by you with alternating currents of high potential, as in primary lines for transformers?
Compare your experience with underground wires used for arc light work, with that with such wires used for direct low potential; and also with such wires as used to convey high potential alternating currents.
Have you any cable lines under rivers or water?
If so, what satisfaction do they give for arc work or other work?
What is the nature of the faults, if any, which have occurred?
How long has such cable been in service, and what is its character?
State in general the result of your experience with underground wires for the various work.
Are your underground wires connected with stretches of overhead wire?
Are thunderstorms frequent in your locality?
What provision do you make to protect the underground wires or cables from induction or high potentials during thunderstorms?
If such provisions be made, is it effective?
Can you furnish any samples of defective sections of underground wire containing faults, with a statement of the conditions of use?

Mr. E. R. Weeks, Kansas City, moved that the report be received and filed, and the committee continued.

Mr. Morris, Nashville, Tenn.—Mr. President, knowing that a paper on the insulation of wires was to be read was one consideration which led me to come here, so as to learn something about that. My company has under consideration the re-insulating of its entire system, and we do not know what is the best. It seems to me that to determine a good insulation is largely the solution of the underground question; and I must confess my very great disappointment with the report of the committee on that subject. I appreciate the delicacy of the committee's task in reporting this wire or that wire—this manufacturer's wire or that manufacturer's wire; but at the same time it is a question that ought to be taken hold of, and there ought to be some answer to our question. I think if these questions were printed and sent out the answers that you would get would be so small in number that they would practically be of no benefit in arriving at any proper conclusion. I am satisfied that the managers of stations are not going to take the trouble to answer those questions, and practically you will have accomplished nothing. We can only receive the report and discharge the committee and appoint a new one, or continue them. But I cannot refrain from expressing my disappointment in regard to that report.

Dr. Moses—Mr. President, there is a large steam hammer at Essen that strikes a hundred ton blow. It is about twenty feet high, but the foundations of that are two hundred feet under the ground. Now although this report consists of but a few lines there has been an immense amount of thought and discussion between us as to how to arrive at a solution of the question—that is, to make a report on insulation and installation that would be really of advantage to the association. I wanted to have specimens of every conductor that was in use laid before this committee, and to have them make all the scientific tests, and to supplement those with all the practical tests that they could possibly devise. For that reason the president selected a committee

of gentlemen, who had every facility in this country for doing the work. They were not prejudiced by association with any particular manufacturing interests, and each had a very excellent laboratory at his service. The Western Union Telegraph Co. was represented, the Bell Telephone Co. was represented on that committee, so to say; that is, their electricians were selected as proper persons. There were other companies represented, and it was thought that the results could be made very valuable in that way. We had Cornell University present by its representative. They were all willing to do a certain amount of work, they said, but they were all determined that they did not want to appear to be advertising anybody's wire. As much as to say that if the sun shone to-day and they were to praise it they were advertising the one who made it. It was true that that was all they were called upon to do—to report on what was good wire. I tried to carry that through, but they were all too modest and fearful of the results. They then tried to throw this matter back on the association, and get what information they could right through them. Mr. Morris may perhaps be mistaken in supposing that the superintendents of the different companies will be unwilling to furnish this information. I happened to be present last evening at a dinner given in honor of the executive committee of this association, and there was one gentleman who is, I believe, present now, who said, "I waive the executive committee part of it; I speak as the superintendent of a station." Now why cannot we get from every man here who represents a company some information that will be of value to this association. They are plain questions; all we want is that they should be truthfully answered, and the committee will winnow out all the chaff from it, and get at some of those jewels that might be thrown broadcast, such as the mayor spoke of.

Mr. J. F. Morrison—It strikes me the original intention was to find out—that is among the laymen—to find out from the scientists, who are members of the association, what is the best material and how it is best to apply that material to bring about the best condition of insulation for air lines mainly. I do not believe any steps have been taken in that direction by any of the committees that have been appointed. The list of questions which Dr. Moses has just read goes to show that they are on the hunt for the same kind of information we are after. We sought to get the information from them. They are coming back now to get that information from the station superintendents. I do not believe you will get that information there. I do not believe that you will get a foundation that will go far enough into the earth to prevent jarring, if you seek to build your foundation in that direction. I do believe that if the chairman of the committee on insulation were to press the case, month by month, during the recess between the meetings of the association, that he would get from the men, the use of whose laboratories we had in view when the committee was appointed, satisfactory data from practical experiments—from experiments made in lines which the superintendents of companies have not been able to reach, and such information as would put us on the right track in all future operations.

The question of how to steer clear of insulated wire seems to be the one most largely in the minds of the men who own the stock in electric light companies. I beg to call the attention of the gentlemen here who belong to the various companies throughout the United States to this statement which I have just made, and to ask them if there are any here who will fail to corroborate it. If the manager of an electric light company selects a first-class insulated wire for his company, the first question is "What will it cost?" He will state to them that it will cost so much. Why, the answer is, there is Mr. DeCamp's company in Philadelphia that buys wire for twenty-five cents a pound. The president, or one of the directors of your company will say, "Why can't you use exactly the same wire?" Well, you can; but you won't have insulated wire; you will have underwriter's wire; you will have cotton insulation which means no insulation. Now I claim that there are to-day half-a-dozen insulated wires which quite nearly fill the bill that we require. But the moment you suggest any one of those then there arises in the mind of every member of the association the fact that you are boosting some man's business at the expense of some other man's business. The next thing is that you are sat upon. Now one of the evils for which I have never been able to suggest a remedy is just this one. You want information. From whom can you get reliable information? From the man who has followed such a course of investigation as enables him to come with something in his hand and say, "Here is an article which will do so and so." The wire man has produced some sort of an insulated wire, and he makes a broad claim for that wire. Now it seems to me that if this committee was to take the wires offered by the gentlemen who claim such and such qualities of insulation, and apply the apparatus and the facilities which their laboratories afford for the testing of that insulation, and give a fearless and unbiased report, such an investigation I believe will very nearly carry out the idea which was in mind when this committee was first appointed. I throw out this suggestion for the chairman of the committee.

Let me repeat what I have said:—If instead of the committee which has been appointed going to the superintendents of stations and asking them for the information which this association has sought—if they will take the facilities which they possess, and will take the material which is now upon the market—the insulated wires for which such claims are being made—and will make practical working tests of those wires, and will give us the result of that, it will be more satisfactory and more in the line of what was intended when the committee was appointed. There is some sort of a substance that is an insulator. There are a number of dielectrics. There are lines for arc lighting underground and in operation. There are cable lines in the air where wires are all bunched together insulated from each other, and they are in successful operation. Every one knows that incandescent light wire is underground, and that a satisfactory insulation has been found for that. Now, then, among the multitude of able men who have turned their attention in this direction, backed up by enormous capital, why cannot we get at some of the practical results which they have achieved? Stop theorizing. Do not let us attempt to build up a theory, but let us get at the practical facts which these men have reached through this laborious and expensive method, which we all know experimenting to be. I make this suggestion for the benefit of myself and the other gentlemen who desire to know what is best to do in the way of insulation. If Mr. Mason gets up—and I see he is moving in his chair—they will say "That is Simplex;" if Mr. Candee gets up, they will say, "that is Okonite;" if Mr. Hotchkiss gets up they will say, "that is Kerite," and they will go through all the "ites," until your head swims and you get no information. They will condemn this man and say he is getting up to advocate his own goods. I am not adverse to that myself, and I think the sooner you break down that idea and devote a part of your sessions to the purpose of getting information, from the only source where you can get it—from the men and companies who have spent their money in this direction, until you abandon this fool notion that you are boosting one man at the expense of another, just so long you will be groping in the dark, and have such a report as that presented by the committee, with blanks for some superintendent of an electric lighting station to fill in with information about something he knows nothing about.

Mr. A. F. Mason—I do not propose to be held back from speaking on this motion by any fear that any one will say I tried to boom a wire. I do not believe there is a representative of any company who would degrade himself, and abuse the privileges of this floor, by any such course, and I do not believe anybody here will suspect me of any such intent. The president will remember that the original motion made two years ago for the appointment of a committee on insulation I had the honor to propose, and since that time I have felt moved to press the continuance of the committee, or the appointment of new committees. So far the work has not been satisfactory, as the gentleman who presented this *quasi* report to-day has stated. The results have been *nil* so far. Personally I do not believe that all the laboratory experiments that these learned gentlemen and this committee could have made, would have been worth one farthing to the members of this association. I do not believe that laboratory experiments upon insulation give us any reliable practical facts. Furthermore, in talking with gentlemen who are of very high standing as experimenters, I learn that such is their opinion. They allow that they cannot make a series of experiments, one exactly duplicating another. So much for that. I think I may say that I fully agree with Mr. Morris in his opinion that we should get but very few answers to those questions if he sent them out, and if we got them, what is the value of each series of answers? First, it depends on the character of the man who writes them, upon his ability, upon his frankness, upon many other factors, and the value of these factors cannot be estimated by the committee. I cannot conceive how we are going to reach the end we want through any such questions. I want to say right here and now, that anxious as I am for the facts that are aimed at by these questions, and earnestly desiring as I do that the whole electrical fraternity shall be acquainted with the facts regarding all insulations—among others the fact that no one insulation is the best for all cases—yet I say I do not believe it is a wise use to which this association may be put—to quote again the words of Mr. Morrison—to boom anybody's goods. I don't want the goods of which I have the honor to be the proprietor to be boomed by this association. I do not believe any other gentleman here wants these goods to be boomed in that way. Mr. President, I shall run the risk of some unkind person saying, "He did not want his goods tested thus," and put myself on the good nature of my brethren by making this motion, that this report be accepted and the committee discharged.

The motion was seconded.

The President—The pending motion is an amendment offered by Mr. Mason that the report be received and the committee discharged.

Mr. Morrison—I object to any such motion. I object to the closing of any channel of information for this association. I do not think that the shutting off of any source of information that may have been opened in times past will be of benefit to the association. I am glad to receive information from Mr. Mason or from any other gentleman engaged in his line. We all know what an honest—I would say a modest set of men the wire men

are. I would never accuse them of being very honest, but modest. But for my own sake and the sake of the other members of this association I hope the gentleman's motion will not prevail. That committee is composed of the most intelligent men in the various lines of business which they follow. If you discharge them you are at the mercy of Mr. Mason and the wire men. If you continue the committee you have got an intelligent body of reference to whom you can refer these matters, and if Mr. Mason comes to me and says, "I have got the best insulated wire in the world," and gives me his samples, I can go to the committee and say, "Mr. Mason claims such and such properties for his goods," and then these despised laboratory experiments come in very well, and you can take these to a chemist, and he will tell you whether the constituent parts of the insulator are such as will carry out the guarantee of the gentleman who offers the wire for sale. I ask that the gentlemen of this association will not vote to discharge that committee. It is a tough job to move to receive and approve a half finished report like the ones the committee has sent in for two or three years, but it is better than no report at all. They may wake up to the facts that the information is of importance to them, and take enough time from their slumbers or pleasures to make up a report that is free from blanks and queries. I hope you will vote down the substitute and accept the report such as it is, because it is the best we can get at present, and continue the committee.

The President—The chair desires to state, in all fairness, that this question has been before the association several times, and at the Boston meeting the committee was continued, upon the ground that sufficient money had not been provided by the association to make certain experiments in this direction, but they were instructed to collate information and make a report. Dr. Moses, for the chairman, stated that they had considerable valuable information. The point now is, if you adopt this amendment or substitute you will treat all that valuable information as practically of no use. It will be in nobody's hand except as an archive, and all the work that has been done will be lost. That is the way it presents itself to the chair. I simply state it so that you can vote intelligently. The question is on the motion to accept the report and discharge the committee.

This motion was lost.

The President—The substitute being lost the question now occurs on the original motion to accept the report and continue the committee.

Mr. Morris—I would offer, as an amendment, that we appoint an entirely new committee, partly of scientific gentlemen and partly of practical superintendents, and let us have a report on the facts as nearly as we can get them.

The President—Does Mr. Weeks accept the gentleman's suggestion?

Mr. Weeks—No, sir. I think it would be better to leave it in the hands in which it is now placed. They have organized a movement that will ultimately bear fruit. It is true that the first returns to these inquiries will be meagre, and the burden of them will be to condemn underwriter's wire, so called. But as times go on, it seems to me, if this matter is pressed vigorously and intelligently, as these men who have been placed on this committee have the ability and power to press it, that we will get some very valuable results. It strikes me too that we will get from the superintendents of the companies who are engaged in actually using these insulators the facts that we want. I appreciate the point of Mr. Mason that it is not in the laboratory alone that these things are to be settled. We might get certain results in the laboratory that would not be borne out by the varying conditions under which these wires are used. I feel that the wise course would be to leave this in the hands of the committee now appointed.

The original motion to accept the report and continue the committee was then put and carried.

The President—We will take up the paper of Mr. S. S. Leonard, of Minneapolis, on petroleum as a fuel. That will be now read by the secretary, or some member in his absence.

Mr. Allan V. Garratt read Mr. Leonard's paper on "Petroleum Fuel," as follows:—

PETROLEUM FUEL.

BY S. S. LEONARD.

The use of petroleum is by no means of recent date; it was known to the ancient Greeks and Romans, being used by them for illuminating purposes, as they had no electric lights in that day.

In fact the word "petroleum" is of Latin derivation meaning "rock-oil." It has been, and is, used for various purposes, from the sure cure of numerous diseases to the generating of steam for electric light stations. It is found in many parts of the globe, although there is but a few localities that are especially noted for its production. In our own country, New York, Pennsylvania, Ohio, and West Virginia produce the greater part of the supply.

Although it was known to the early settlers of these states, very little importance was attached to its value. I presume that there are none so young here but well remember the oil craze, and the saying which was heard almost daily of "So and So" has "struck ile." Perhaps some of the members of this convention were fortunate enough to strike "ile," and possibly some were unfortunate enough to have been struck by "ile." But to return to our subject, Petroleum Fuel: To say that it is a new fuel would hardly be correct, for petroleum has been used as a fuel for a number of years; experiments to determine its practicability as a fuel have been creating a great deal of attention from those interested in the matter for the last twenty years, and is now occupying the minds of some of our ablest engineers and inventors. Quoting from a very able paper on this subject by Chas. E. Ashcroft, which was published in the Boston *Journal of Commerce*, May 26th, 1888, Mr. Ashcroft says:

"That the calorific power of petroleum for the purpose of generating steam, and the evaporation of water is several times greater than that of ordinary coal." The successful use of oil as a fuel has, however, been of very recent date, yet so rapidly has it grown in favor that to-day it is regarded as a strong competitor of coal for steam generating purposes or where heat and fire are wanted. It was with a great many knowing winks and nods of the head from the engineers and firemen, who laughed at the idea of making steam by the use of oil, that the writer attempted the use of petroleum as a fuel; of course it would not work, and it did not work, why? because those who were using it did not want it to, as they were afraid some one would lose his job. We had seen enough of its workings to satisfy ourselves that it could be made a success, and the result is, that to-day we are saving from 20 to 25 per cent. on the cost of the fuel and 50 per cent. in labor, and these same men who laughed so hard on the start at our attempt to use oil would feel that this world was a poor place to live in, were we to return to the use of coal, for not only their hearts but their backs would certainly be broken.

Its advantages over other fuels are many; in the first place, it is much easier handled, a steadier fire is easily maintained under your boilers, consequently the steam is kept at a more even pressure, a very important thing in the running of electric lights; there is no opening of furnace doors, allowing cold air to come in contact with the boilers, and there are no impurities in the oil such as abound in coal; when through with it by a simple turn of the wrist your fire is put out, and your ash pits are as clean as they were before the fire was started; in less time than it takes to tell it you can start the fire. It is only rivaled in handling by natural gas, and even then, unless we have all the modern appliances for the handling of this gas, it is far easier to manipulate.

Permit me to describe the arrangements for the handling and use of this oil put in under the supervision of the writer.

The oil is received in tank cars holding from 90 to 150 barrels each (42 gals. to a bbl.), from these cars it is drawn off through a valve in the bottom of the car to a storage tank or tanks, there being two of them, holding about 320 bbls. each, these are placed underground so that the oil runs from the car into them by gravity; care should be taken not to spill the oil or stir it up more than is possible, as the odor from it is fully equal in strength to new mown hay if not quite as agreeable. To prevent the stirring up of the oil, the supply pipes entering through the top of the tanks run nearly to the bottom, so that the tanks are practically filled from the bottom. In the top of each tank are man-holes and a vent pipe; this latter is extended above the tanks a short distance. These tanks, which are boiler shaped, are placed end to end with a space of about eight feet between them, this gives room to get at the various pipes; they are joined together at the bottom by a pipe

which also connects with the supply pipe running to the boiler room; then in the bottom of each is a drain pipe which will admit of cleaning them out whenever necessary; there is also a gauge glass in the end of each to show how much, if any, water is in them; there is also a gauge, having a copper float, which indicates the amount of oil in each tank. In cold weather a small steam coil is inserted in the tank car around the mouth of the valve to heat the oil so that it will flow readily, for when the thermometer gets in the vicinity of 30° or 40° below 0 the oil is apt to be a little thick. Care should be taken not to heat the oil too much, for when hot it generates considerable gas, which is not only very odorous, but is really the cream of the fuel.

I think it an advantage to have the storage tanks underground, there being less danger from them in case of fire, and during the winter the oil is less likely to chill. An open light should never be used near them, although the oil itself is really hard to ignite unless heated to a certain degree; still there is apt to be more or less gas around, which is quite explosive if brought in contact with fire. The supply pipes to the furnaces are provided with a valve where they enter each tank, also one in the fire room; this pipe, a two and one-half inch one, is enlarged to a six inch for about four feet, and in this six inch pipe a small steam pipe is inserted; with this the oil is heated from 130 to 140 degrees, this lightens it so that it burns more readily, or I should say is turned into gas.

We now come to the burners, which are also fed by gravity, as the storage tanks, although underground are still higher than the furnaces.

One might suppose in view of the recent introduction of petroleum as a fuel, that some difficulty might be experienced in obtaining a burner, but their name is legion, and they are as numerous as electric light systems, and like them in another respect, each man's is the best. Our experience has been that the more simple the burner the better the result; one that thoroughly vaporizes the oil before burning it is, we think, preferable to one that burns the oil; in the former there can possibly be no waste. In furnaces where we have been using this kind of a burner the bricks are as clean as they were the day they were put in. Steam and hot air are the other ingredients that are used in connection with the oil, and an abundant supply of the latter we have found adds very much to the efficiency of the fire.

Regarding the proper settings, circumstances will determine that to a certain extent. An excellent plan is given by the Standard Oil Co., in their pamphlet on "Oil as a Fuel;" this we have adopted with a few modifications, which we found necessary by experience. There is no doubt but that a hotter fire can be obtained from oil than from coal or wood, and when properly used the smoke nuisance is solved which has been agitating the minds of the people of some of our large cities, for there is not a particle of smoke to be seen issuing from the stack, not even when everything is running full blast.

A word as to its danger. When properly put in and handled with ordinary care, or when good common sense is used in burning this oil, I cannot see why it should be any more apt to cause trouble than coal, although the insurance companies insist on higher rates when used. I think it more from ignorance of the subject than from there being any more danger; at the same time I am willing to admit that it could be put in and used in such a way as to greatly increase the danger of fire. So might your house be wired for electric lights, piped for gas, a kerosene lamp hung, or your gasoline stove filled, in such a manner that the fire risk is much greater than your neighbor's who uses electric lights, gas, kerosene or gasoline the same as you do, but has his put in properly and handles it as it should be. As to its economy over coal, I have already mentioned that there was a saving of from 20 to 25 per cent. on the cost of fuel, and from 40 to 50 per cent. in labor. From tests recently made by us, the following figures were obtained:—111.34 h. p., running six hours, used 250 gals. of oil, costing $5.50, or at the rate of 70c. per 100 h. p. per hour; 104.8 h. p., running six hours, used 3,461 lbs. of coal, costing $5.45, or at the rate of 86c. per 100 h. p. per hour. Another test gave the following figures: 96.45 h. p., running eight hours, used 4,014.75 lbs. of coal, costing $6.32, or 80c. per 100 h. p. per hour; 115.54 h. p., running 7 hours, used 233 gals. of oil, costing $5.05, or 62c. per 100 h. p. per hour. On the above figures, oil is from 17 to 32 per cent. cheaper than coal. The highest evaporation made with oil was 14.8 pounds of water per pound of oil, with feed water at 103; and with coal, 5.38 lbs. of water per pound of coal, feed water at 103. The coal used was a good grade of Illinois lump, costing $3.15 per ton, but which is usually worth $3.25.

In the matter of labor one man can easily attend from 7 to 10 boilers of 150 h. p., and then have less to do than he would were he firing one boiler with coal. After a week's run with oil your boiler flues are much cleaner than they would be from the use of bituminous coal for one night, especially Western coal. Your fire room can be kept as clean as your dynamo room. There being no ashes you are saved the expense of handling them as well as the dirt, and the former is no small matter where some twenty tons of coal are being used every twenty-four hours. I might say that the above tests were made during a part of the day's run, and it is our opinion that a more favorable showing could be made with the oil, where a larger number of boilers are in use. It seems to work better with a good fire than where a small fire is sufficient. With our pipe lines affording a cheap method of transportation the future of "petroleum fuel" is assured, and I think there is no doubt but with true Yankee ingenuity a burner, or some method, will be brought forward by which the use of petroleum as a fuel will be greatly improved.

The President—In connection with this paper I desire to read the following letter, as due to Mr. Leonard.

Minneapolis, Minn., Aug. 22d, 1888.

S. A. Duncan, Esq.,
Pittsburgh, Pa.:

My Dear Sir.—I herewith hand you the paper on fuel oil that you requested me to write when here. All that I have to say is that if you take the time to look it over, and think after doing so that it is not worth the while to take up time that would undoubtedly be spent to better advantage by having it read before the convention, do not hesitate to lay it one side, as no feelings will be hurt. Should you, however, think best to present it to the convention, I shall feel very well pleased if I have been able to say anything that will be of any benefit to the association. It will be impossible for me to be present.

Yours very truly,

S. S. Leonard.

I would just say that the way this matter came about was that being in Minneapolis some weeks ago I walked into Mr. Leonard's station and wanted to know where he got natural gas, and laughingly he said, "We use gas in a different way." Then the question came up as to the economies and so on, and I found that he obtained such satisfactory results from the use of petroleum, and was so entirely satisfied with the economies as compared with his former experience with coal, that I asked him to prepare this paper and it is now before you for discussion. I hope you gentlemen will go into it.

DISCUSSION.

Mr. Morrison—As Mr. Garratt was reading Mr. Leonard's paper I asked Mr. Pope to analyze those figures. Here they are: 250 gallons of oil cost $5.50; that is seventy cents per 100 h. p. per hour. Coal costs eighty-six cents per 100 h. p. per hour, a difference of sixteen cents per 100 h. p. per hour. If you take a station of five thousand or six thousand horse-power and run a year that is a considerable item.

This paper is a very startling one to me. I saw it yesterday I think. It is a most startling one if the details are true. We have no reason to doubt the statements; I have none. If any gentleman has made any experiments in that direction that will throw a doubt on these statements I hope he will get up and say so.

In 1865, that is twenty odd years ago, I was a telegraph operator at Parkersburg, in West Virginia. They did not get coal enough for their use. There was a man named Shipley who was engineer in the Swan House, a tavern right across from the

telegraph office, and there for the first time I saw the burning of petroleum. There was plenty of it there then. Wood County had got into the habit of squirting oil out of the ground, as in Pennsylvania, and oil was very cheap. I think it is cheaper to-day than it was then. If this is true I want to know something about it for we will be running six or seven thousand horse-power within the next six months or so. There is another item not mentioned in the paper. It costs us twenty-five cents a load, with coal, to haul the ashes away. I have not at the end of my tongue the figures of our station. I am sorry Mr. Evans is not here to give them, but we use a low grade of fuel. It costs a little less than three dollars a ton. It is known as screenings and soft slack coal. It has always been an open question with me whether there was very much economy in the end with it, but it costs well up to three dollars before you get through with it. Now it costs you three men to handle it, and out of this trash that you burn the ashes are nearly fifty per cent of the fuel you put on the grate bars. Of course you must make allowance for these statements because I am making them off hand. But I observe if we burn say fifty or sixty tons of coal of a night we generally have thirty or forty cart loads of ashes to haul away the next day. Now that goes to show that pretty near half of the stuff comes out in the form of ashes, sand and slate from the mines, and so on. That is another item that you can credit up to the economy of this petroleum fuel. In the new station we are going to build I shall equip one battery of boilers with coal oil. Mr. Weeks, of Kansas City, is going to make large additions to his plant, and I hope he will do exactly the same thing. What do you pay for coal in your country Mr. Weeks?

Mr. Weeks—$2.56.

Mr. Morrison—What kind of coal?

Mr. Weeks—Bituminous nut.

Mr. Morrison—How much do you use per horse-power per hour?

Mr. Weeks—About six pounds.

Mr. Morrison—On a Buckeye engine?

Mr. Weeks—No, Hyde engines.

Mr. Morrison—I would suggest that every gentleman who is a member of this association and who contemplates any additions to his plant will take a copy of this paper and analyze it carefully. If there is something he does not understand let him ask Mr. Leonard to explain it and then try it practically himself.

Mr. Frank Ridlon, Boston—I have been superintendent of a large coal tar company. From that material we got out various substances that were valuable for coloring matters. We finally came to the last portion or that which was known as dirt oil. It was used at that time for the making of glass, and was also sold latterly at a somewhat higher price for the creosoting of wood for railroad ties, spiles, etc. We at one time found it impossible to get a sale for that article, and when we had to sell it for about a dollar a barrel we found it cheaper to burn it and we did burn it with very good satisfaction, although the apparatus for using it was very crude indeed, not only as to the economy of heat but as to the wasting of fuel. We simply had a perforated plate and another plate that was not perforated underneath and let the oil drip down upon it; but we found it a very fine material to use. Referring to the matter of ashes, that was quite an expensive matter—carrying some distance; so that when we could not get a dollar a barrel for it we found it cheaper than burning coke for which we were then paying about $2.50 a chaldron.

Mr. DeCamp—I would like to ask how long Mr. Leonard has been using oil.

The President—The chair will state that he was there about the 10th of July, and Mr. Leonard had then been using that oil several months. He had first made the experiment with smaller quantities of oil, but the company had got to that point where he had put these tanks in as reservoirs, and they ran in a side track alongside his station and emptied into his reservoir tanks. It is as clean and nice a piece of business as I ever saw.

Mr. DeCamp—Mr. Leonard's paper is a very remarkable one. Some two or three years ago I paid some considerable attention to the subject of oil fuel. Several methods have been adopted in Philadelphia for the utilization of oil, but the parties who have adopted them have finally abandoned them. I was never able to learn just what their reasons were but they used them with apparent success for some time and, as they said, with great economy, and then they dropped it. As I see, figures are presented in Mr. Leonard's paper on the first cost of oil fuel as compared with coal. There is not a very material difference, but the labor item and other expenses extended to coal which would not be extended to oil is quite sufficient to make the matter of very great interest to this association. I have recently got through with a test of coal. We have been using one particular coal for about four years. In fact we do not seem to be able to get any other coal that is equal to it; our recent test was made with a new coal as compared with the coal we are now using. There was a difference of eighty-five cents a ton in price. Our coal cost us in one instance sixty cents per hundred horse-power per hour and in the other, sixty-three cents; the sixty-three cents being far the lowest priced coal Now we differ from Mr. Morrison; we do not use screenings. I have come to the conclusion in the last two or three years that the best coal was, taking all things into consideration, the cheapest coal to use. In the one case the cheaper coal gave about three and a half cart loads of ashes to every ton of coal, and in the better class of coal it was a trifle less than two. Our ashes cost us, from one station seventy-five cents a load to haul and from another station forty cents. In the comparison between these two coals on the point of labor, the better coal would run a full fourteen hours without the fire being cleaned, and with the other coal we would have to clean fires certainly sometimes during the run. That would necessitate another man as a laboring man in the fire room. I made up the estimate on those two coals. There is a difference of eighty-five cents a ton in price between them. The labor and everything else taken into consideration was equal to about $1.10 a ton. One coal cost us $2.90 put in the boiler hole and the other cost us $2.75. Our consumption of coal is about 12,000 tons a year. The figures presented by Mr. Leonard are just about on a par with the best coal we use; so that there is no doubt of the importance of that paper, if Mr. Leonard is correct in his figures.

Mr. M. J. Perry, Providence, R. I.—Mr. President, the gentleman from Baltimore who is using coal dust and soft coal mixed has had an experience quite different from mine, although the net results of Mr. De Camp's experiments and also the net results of the experiments of Mr. Morrison were very similar, and they seem to be very much like the result of using the oil fuel. That is to say, about 62 one-hundredths of a cent to 66 one-hundredths of a cent per hour per horse-power. Last autumn our company having decided to build a new station, and having determined on some radical changes in the arrangement of the steam plant, I thought it would be an excellent thing to put on some first-class steam engineers and ascertain, not what we might do by fancy firing and jockeying, but to ascertain just what we were doing in every-day practice, and we selected for that purpose a gentleman very well known, who was trained under Mr. George H. Corliss—Mr. John T. Henthorn, a member of the American Society of Civil Engineers and also of the Society of Steam Engineers, and asked him to determine what we were doing. We made no changes whatever. The result was a horse-power for about 62 one-hundredths of a cent per hour. We used for fuel three parts of anthracite dust—not pea and dust but simply the dust; no pea in it whatever; with one part of Pocahontas or an ordinary flat-top coal. The result of that was about 17 per cent. of ash. Mr. Morrison spoke of 50 per cent. and that caused me to mention this—about 16 or 17 per cent. Our runs were good runs. We made 48 hours straight tests, running right through two days and two nights. Having some power business and also some all day business we run our stations 24 hours. The result was—which confirms the statement of Mr. Morrison and also that of the gentleman from Philadelphia—about 62 to 66 one-hundredths of a cent per hour per horse-power, and in the ash, as I say, about 16 or 17 per cent. in weight. Now another very peculiar thing was that when we just concluded our first day's run, it came on raining and continued to rain for the next 24 hours. So far as we were able to ascertain there was not a change of a single light. The same hours were run, the same number of lights were run, but the run during the rain showed an increase of 20 h. p., the average of the 24 hours being at the rate, I think, of about 142 h. p. per hour for the first 24 hours. The second day, when it was raining (it poured the whole 24 hours), it was just 162 h. p. per hour for the 24 hours. We are using underwriter's wire all the way through. We have no especial interruption from the grounds, but general leaks all along the line. The results of coal using and of oil burning seem to be about the same in the four stations—the Baltimore, the Philadelphia, the Minneapolis and the Providence station.

Mr. Morrison—I would rather take the gentleman's statement than my guess work. The gentleman has stated these as actual facts from tests.

Mr. Perry—Yes. Our engines were indicated every 20 minutes.

Mr. Morrison—Now in regard to the ash?

Mr. Perry—As we intend to abandon the high speed engine—I should say the high pressure engine (we propose to run high speed the same as before but we will use a compound engine and surface condenser) I wanted to know just what we were accomplishing with the high pressure engine, and to ascertain what benefit we would derive from adopting the other engine. We shall go into the new station in the course of three or four months. We used an Armington & Sims engine. We have not yet fully decided what engine we are going to use except that it will be a compound engine with surface condenser. We intend to arrange the station so as to get a uniform load while operating the engine.

The President—Did you include the cost of hauling refuse matter?

Mr. Perry—No, sir.

The President—Then you can figure 20 per cent. at least for that.

Mr. Perry—It costs us 28 cents a load to haul the ashes.

Professor Van der Weyde—A year ago I had a rare opportunity to test the economy of coal compared with petroleum. I was testing a new style of dynamo in order to determine the economy of the alleged improvement. The parties interested in it concluded to make another test, and by means of petroleum fuel.

The petroleum boiler was furnished with the furnace. I had the consumption of petroleum watched carefully. I have not in my memory the correct figures, but I can tell you the upshot of the results obtained. The dynamo was tested also. The steam power furnished to it I had carefully tested with indicator diagrams. I made the test as well as a conscientious scientific application could make it. The result was that when compared with the consumption of coal, the petroleum was a great deal dearer notwithstanding that the coal is more expensive here in New York than in many other places. I remember the upshot only, which was this—that as long as crude petroleum will cost more than 40 cents a barrel it is cheaper to run with a slack coal. In stating that result to a prominent Philadelphia manufacturer he told me that they had had the free use of gasoline from some petroleum furnace there, and so they used it for a time until the gasoline got more valuable in the market and they could not get it gratis any more. Then they stopped, because if they had to pay for the gasoline it would be much cheaper to use coal, and they returned to the use of coal. Only where the peculiar circumstances admit of getting petroleum cheap can it be used to advantage. For instance, in Russia they use petroleum largely because they have no coal; but in the City of New York I am perfectly satisfied that notwithstanding there is some saving in the handling of the fuel when we use petroleum, that coal is the cheaper fuel in New York city.

Mr. Morrison—What did you pay for the petroleum, Professor Van der Weyde?

Professor Van der Weyde—The petroleum was $1.00 a barrel.

Mr. Morrison—I want to find out what this experiment is based on—the price per gallon for oil and the price per ton for coal. I want to ask the gentleman upon what this experiment was based—the cost of the oil, the cost of the coal, the length of the test, etc.?

The President—Can you inform the association, Professor, the length of time of the test, and the cost of the fuel of each description?

Professor Van der Weyde—The test for petroleum was for about a fortnight.

Mr. Morrison—How large a plant?

Professor Van der Weyde—The plant was small. I must confess that the plant was not more than enough to furnish about 20 h. p.

Mr. Morrison—You used crude petroleum I suppose?

Professor Van der Weyde—Crude petroleum.

Mr. Morrison—It cost you how much?

Professor Van der Weyde—A dollar a barrel. I made a calculation at that time that if we could have had the petroleum at 40 cents a barrel, then it would be cheaper. I must also say that the arrangement for consuming the petroleum was very fine—one of the best I have seen, while the arrangement for the coal consumption may not have been so perfect. It was an ordinary horizontal boiler.

Mr. Morrison—What did you pay for the coal?

Professor Van der Weyde—I believe it was $3.50 a ton delivered at the place.

Mr. Weeks—What kind of coal.

Professor Van der Weyde—Anthracite coal?

Mr. Morrison—Do you think that experiment would be as reliable as using say 100 h. p.?

Professor Van der Weyde—That is a question I would decline to answer. My experiments were with an engine of about 20 h. p.

Mr. Morrison—What was the difference in the cost?

Professor Van der Weyde—I have not the figures in my mind, but I know this, that the result of my calculation was that when we could get petroleum for 40 cents a barrel then we could make steam as cheap as with the coal.

Mr. J. M. Pendleton, New York—In view of the discrepancy in these results I thought it might be interesting, referring to Mr. De Camp's experience, to ask him whether he had ever heard of a petroleum fire burning the iron. I recollect many years ago that that was the complaint of many engineers, and it might be interesting to know if he ever heard of such a result being caused by the use of oil as a fuel.

Professor Van der Weyde—I am glad Mr. Pendleton mentioned this, because in my observation for 14 days in a petroleum furnace I saw that the iron suffered greatly, and I was expecting that if it was used for a protracted time it would give out.

Mr. De Camp—I never was able to learn anything about that. The last and most important effort made in that direction that I know of was in a shoe factory. The proprietor is a man of large means, and a progressive man, and he had very small facilities for coal storage and he went to a very considerable expense, I judged from the looks of his place, to put in the boilers for oil fuel suitable for his factory. I suppose he used 50 h. p. I do not know whether he ever published them or not, but he made statements very freely that he was saving a great deal of money in his fuel account. I do not think he ran more than six months when he abandoned it. Whether he found his boilers were burning out or not I never heard.

Professor Van der Weyde—Another illustration comes to my mind. At Hastings, N. Y., there are gas works where petroleum is used to be converted into gas. They commenced with coal as fuel and after a while they tried petroleum, and instructed by the experience I had had before with a dynamo I told them I did not expect they would be satisfied. It turned out that way. They abandoned the use of petroleum and returned to the use of coal.

The President—The hour for adjournment is getting very near, and this is a very interesting subject. This question of burning out boilers with gas is all nonsense—with petroleum gas—because it is identical with natural gas when it is properly burned under boilers, and there are many boilers used with natural gas burning under them lasting longer than any with coal under them. In regard to the question of economy, the only thing I know about it is the statement of Mr. Leonard. Mr. Leonard is a practical man and is running a good sized station, and I have no doubt he will stand up the figures he has given. If the points made are such as to induce this association to have a committee to see if they can get a few more statistics on the subject, it would be well. But so far as the present discussion is concerned, it will have to close at this time.

Mr. Morrison—I hope we may be able to hear from Mr. DeLand before adjourning.

Mr. Pendleton—I beg to say in reply to Mr. Duncan's remark that the action is different in burning gas under water and burning the petroleum in the manner spoken of by Mr. Leonard. In one case you have the pure gas burning and in the other case you have a mixture of steam and hot air with it. It is a well-known chemical fact that at white heat, usually, steam is decomposed, and the action of this mixture upon the iron in the vicinity would be very different from that of pure gas. I only call attention to the fact that the burning of natural gas by no means solves the question of burning petroleum where hot steam and air are burned with it.

Mr. B. E. Sunny, Chicago—The company that I am connected with has a station just south of the city limits in Chicago. Our coal costs us about $900 a month. We were buying it by the car load. The coal was wet at the mines; it was generally wet when it was weighed, and by the time the car got to us we found it short about 20 per cent. in weight, so we got about $700 worth of coal and paid $900 for it. On investigating this question of oil burning, and corresponding with a large number of gentlemen who had some experience and who had been using oil burners for a long period, we found that in most instances the same results could be had out of two barrels of oil as out of a ton of ordinary bituminous coal. Our coal was costing us about $3.00 a ton. We could buy oil for 60 cents a barrel, so that the equivalent of one ton of coal would be $1.80, making a saving of $1.20 on a ton of coal. The saving that we expected to get on the change from coal to oil figures at the difference between $957 a month and $540 a month, and we make a saving of $45 for the salary of a coal passer, and $12 for hauling the coal in and taking care of the ashes. We expect to make in any event a saving of 35 per cent. although the figures guaranteed to us by the men who are handling oil burners, and the figures are said to be reliable by men who have experimented, would indicate that there will be a saving of 40 per cent.

With regard to Mr. Leonard's figures as to the economy, I should say that this fact ought to be taken into consideration; viz., that the oil cost him perhaps two and a quarter cents a gallon in Minneapolis, while it costs a cent and three-quarters in Chicago. With regard to the burning out of the boilers, I found that that largely depended on whether you could distribute your flames all around the boiler, But there are several methods whereby you can distribute your flame so equally that there will be no effect on the boiler whatever, and you can get the same result out of the use of oil as you get from the use of coal with respect to the burning of the boilers.

Mr. Fred. DeLand, Chicago—Mr. DeCamp asked how long the experiments at Minneapolis had been carried on—about nine months if I remember rightly. It was started the latter part of December or January. There is an experiment going on at New Orleans that will probably be interesting. It is the Louisiana Electric Light and Power Company. Morris J. Hart is the general manager, and he would probably give you gentlemen all the information you desire if you correspond with him. I was down there several months ago. It is stated he has the largest station in the world in capacity. He has a capacity of nearly three thousand arc lights. The horse-power, I believe, is over 1,200. He had been in the habit of purchasing his coal and having it shipped in barges down the Ohio and Mississippi River, and wheeled in barrels 400 yards from the dock into his station. He found that by using oil he could save thirty-one per cent., and he brought that about in this way: He purchased his oil, of course, from the Standard Oil Company. He sunk two large tanks in the ground each containing 100,000 barrels of oil. The switch passes his station. The cars are brought down to the tanks, emptied there and taken back. The saving came about in the wheeling out of the ashes, the cost of hauling the coal from the barge to the fire room, the doing away with one or more firemen, and other little incidentals; but the net result at that time was a saving of thirty-one per cent. over the cost of burning coal. I

know that Mr. Hart would gladly give this information to any one who would correspond with him.

Mr. F. R. Colvin, Baltimore—I was at that station a few days ago, and the situation there is interesting. Mr. Hart has one battery of boilers running by petroleum and another running by coal right next to it. I could not give any technical data, but I could get it of Mr. Hart. Mr. Hart's brother I believe is in the city.

The President—This is certainly an interesting discussion, but we will have to pass it and adjourn until to-morrow morning at such hour as will suit the convenience of the convention. Before doing so I desire to announce the committee on place of meeting, which will be as follows: C. A. Brown, of Chicago, E. R. Weeks, of Kansas City, T. Officer, of Council Bluffs, A. J. DeCamp, of Philadelphia, and H. D. Stanley, of Bridgeport.

The first business to-morrow morning will be the underground question, and an exhibition, I understand, will be made for the information of the gentlemen of the convention.

The convention then adjourned until Thursday morning at 10 o'clock.

SECOND DAY'S PROCEEDINGS.—THURSDAY MORNING'S SESSION.

The President—Gentlemen, this morning's session is to be devoted exclusively to the question of underground conduits or conductors in the City of New York.

We will first have read all communications and clear up the general business on the secretary's table, after which we will take up Dr. S. S. Wheeler's paper, then the paper by Mr. E. G. Acheson, and then the one by Mr. A. C. Chenoweth.

The secretary has some communications to read.

The secretary then read a communication from Mr. Somerville P. Tuck, as follows:—

August 27th, 1888.

HON. S. A. DUNCAN,
President National Electric Light Association,
Brunswick Hotel, City.

Dear Sir—I have taken the liberty to send you by mail this day a package of one hundred circulars relating to the Paris Exposition of 1889.

Mr. Abdank-Abakanowicz, the representative of the syndicate which has contracted for the lighting of the exposition, is now in this city, having brought to this commission an official letter of introduction from M. Georges Berger, the Director-general of the exposition. I enclose you a clipping from an electrical paper which will give you the details of his mission. I also enclose you blank form of application for subscription to the stock with extracts from the by-laws of the syndicate.

At the request of commissioner-general Franklin, Mr. Abdank cabled the president of the French syndicate on the 22nd instant, asking if they would receive until October 1st subscriptions to its stock on the part of American electrical companies, should such companies desire to subscribe, and in answer thereto a cable was received from the president to the effect that no engagements could be made as requested but that the syndicate would do all in its power to receive subscriptions made previous to October 1st next. Mr. Abdank informs me that he will await your convenience and be ready to make all explanations that may be desired in regard to the matter in which he is interested, and I am sure that he will receive a most cordial reception and due attention.

Thanking you in advance for anything which you may be able to do for him, I am your obedient servant,

SOMERVILLE P. TUCK,
Assistant Commr.-General,
Per. R. W.

The President—This communication will be received and filed, and the gentlemen who desire to look into the matter will find blanks on the secretary's table, and I think, in view of the importance of the general exhibit which is to be made at that time, that we will all be interested in at least looking up the matter.

The secretary next read a communication from James Allison, president of the Centennial Exposition of Cincinnati, as follows:—

Secretary's Office, Cincinnati, Aug.

DR. OTTO A. MOSES,
Chairman Executive Committee, Nat'l Elec. Light Assoc'n,
131 East 73d St., New York.

Dear Sir—The commissioners of the Centennial Exposition of the Ohio Valley and Central states wish to call the attention of the members of your association to the electrical features of the exposition, and wish to submit a brief statement of what is to be seen in that line together with an invitation to all who can do so to visit us.

It has been the intention of the commission to make electric lighting a special feature of the exposition, and they have taken especial pains to have a variety of systems shown and to display the apparatus to the best advantage. As a large amount of light was required for illuminating the buildings, arrangements were made with five manufacturers of electric light machinery for the use of their apparatus, the exposition using the same for service, and the companies having the advantage of large exhibits in regular service.

The following companies are furnishing apparatus:—

The Westinghouse Electric Co., Hartford, Conn., 8 dynamos and 230 arc lamps. The Western Electric Co., Chicago, Ill., 8 dynamos and 225 lamps. The Mather Electric Co., the Edison Co., and the Queen City Co., of Cincinnati 2-500 light dynamos and 1,000 incandescent lamps each. Four of these plants arranged in a combined station situated in the Park building, each lamp driven by a separate engine, the whole making a fine exhibit, the other being located in the Pioneer Hall, on account of its being arranged for after the general plant had been designed.

The lamps are distributed all through the buildings, being used for illumination and decoration; about 500 incandescents being used for the Art Gallery, about 600 for show cases, 900 for decorating Music Hall, 150 lamps for lighting the Park building and the Government Exhibit, and as many more for the Machinery Hall, and about 100 for the out-door illuminations.

This latter has been made a special feature, and show the effect of tower and street lighting to perfection. Besides this there are several private exhibits of incandescent lights and some motor exhibits, among them a 50-h. p. generator and about 25 small motors exhibited by the Queen City Co. An exhibit of constant current motors by the Card Motor Co., of Cincinnati, O., the current being furnished by a Waterhouse Dynamo, and two 2 h. p. motors furnished by the Mather Electric Co. In addition to this, the commissioners arranged, at great expense, with the local Edison agents for a decorative and novelty display, which has proven a great attraction. About 2,000 incandescent lamps are used in designs such as illuminated fountains and cascades, umbrellas, Christmas trees, revolving flower gardens, etc., the lamps being flashed at intervals, giving a very fine effect.

We hope the members of your association will find it convenient to come and see this display, and we think they will be well pleased.

Yours very respectfully,

JAMES ALLISON,
President, Centennial Exposition.

The President—The communication will be received and filed.

Mr. Foote, of Cincinnati—In behalf of that communication, Mr. President, I wish to say that the Centennial Exposition in Cincinnati will probably show the best electrical exhibits ever seen in this country. We are to have a grand display showing electricity in competition with gas, and I think it would be well for every member of the association to go to Cincinnati and see it. I would make the announcement, in behalf of the commissioners of the exposition, that the members of this association who will call at the secretary's office and present their cards of membership in this association will be given tickets of admission to the exposition.

The President—Gentlemen, you have heard the statement that those who bear cards of membership in this association and who intend going to the Cincinnati Exposition will have a card furnished them which will admit them to the exposition free.

The secretary next read a communication from W. H. Eckert, announcing that the Metropolitan Telephone and Telegraph company had placed a telephone in the hotel for the use of the association.

The secretary next read a communication from A. S. Hibbard, announcing that the American Telephone and Telegraph company had placed a long-distance telephone in the hotel for the use of the association.

On motion the thanks of the association were voted for the courtesies extended in the letters of Mess. Allison, Eckert and Hibbard.

The secretary next read a communication from Mr. McDonald, of Fort Wayne, Indiana, and also a communication, attached to the former, from Mr. R. B. Rossington, as follows:—

Fort Wayne, Ind., May 30th, 1888.

MR. W. H. HARDING,
Sec'y National Electric Light Association,
11 South St., Baltimore, Md.

Dear Sir—Enclosed find copy of lecture from R. B. Rossington, freight agent at Fort Wayne, which will explain itself. We should be very glad, indeed, if you would take this matter up with the traffic association committee, and see if the classification on carbons cannot be changed; as it is, the freight charges are exhorbitant. Any assistance that we can render in this matter will be cheerfully furnished.

Yours truly,

FORT WAYNE JENNEY ELECTRIC LIGHT,
By R. T. MCDONALD, Treas.

———

Fort Wayne, Ind., May 28th, 1888.

MR. R. T. MCDONALD,
Treas. Fort Wayne Jenney Electric Light Co., City.

Dear Sir—Your letter of the 15th inst., relative to excessive rate on shipments of carbons from Pittsburgh, has been referred to Mr. Orr, division freight agent, Pittsburgh, Pa., who makes the following reply: "Electric light carbons boxed are classified as first-class, at which shipment in question was billed. It would

be necessary to have a change made in classification before we could do anything, and besides we have had no complaint from shippers." Judging from the above from Mr. J. P. Orr, I would think it advisable to take matter in with shippers and have them petition the central association committee for a change of classification of carbon, as it is necessary that shippers as well as consignees shall make complaint of such matters before they will be entertained by the company.

Yours truly,

R. B. ROSSINGTON,

Freight Agent, Penna. Co.

The President—Gentlemen, you have heard the communication. It will be received and filed, and the chair would suggest that each member of this association engaged in the lighting business should file with the secretary a petition regarding the question of the classification of freight rates for carbons. That being done we will then take up the subject through the executive committee and may possibly be able to obtain something that will benefit us all. There being no objection, that will be the action and the communication will be referred to the executive committee. The secretary has already, under direction of the executive committee, sent out communications to the different companies, but has received very meagre responses. Now, gentlemen, it remains with yourselves whether you will take this subject up and press it. The secretary can do nothing until he receives sufficient petitions to act upon. If gentlemen will promptly file petitions, or a statement of their views in regard to this matter with the secretary, the executive committee will at once attend to the matter.

The secretary next read a communication from Professor Elihu Thomson, tendering his resignation as chairman of the committee on insulation and installation.

The President—Gentlemen, you have heard read the communication of Professor Thomson resigning his position as chairman of the committee on insulation and the installation of plants. What shall be done with it?

On motion, duly carried, Professor Thomson's resignation was accepted.

The President—The next question is, shall the chair appoint some one to fill the vacancy, or shall it be left to the committee to select their own chairman?

On motion, it was ordered that the vacancy in the committee be filled by appointment of the president, and that the chairmanship be left to the selection of the committee.

Mr. A. R. Foote, Cincinnati—Before we proceed with the reading of papers, Mr. President, I ask permission to offer a resolution touching the address of Mayor Hewitt yesterday.

The President—The resolution may be read.

Mr. Foote—I offer the following resolution :—

"*Whereas*, The Hon. Abram S. Hewitt, Mayor of New York city, has honored this association with an address of welcome; and,

"*Whereas*, in his address he has given a concise and impressive presentation of the importance to civilization of the utilization of electrical force in the mechanical service of the people, which is second to none ever before offered ; and,

"*Whereas*, In so doing he has announced sentiments indicative of the man in his complex character of philosopher, statesman, politician and master of business affairs ; therefore,

"*Be it Resolved*, That as a mark of appreciation of his masterful grasp of the importance of the subject, his clear-sighted and generous presentation of it, and his kindly courtesy, the secretary of this association be and he is hereby directed to print an authorized copy of said address in pamphlet form, and supply the same to members of the association at a price ten per cent. in advance of the cost of production."

The adoption of the resolution was moved and seconded.

The President—Gentlemen, you have heard the resolution read. What is the pleasure of the convention?

Dr. Moses—I would respectfully suggest to the mover of the resolution that the question of cost of the pamphlet be entirely eliminated from it, and that instead of the publication of the address,—since that address has been read by several millions of people this morning in the newspapers, there is no necessity for us to circulate it ; it will become a part of the printed proceedings of our meeting, anyway,—I would suggest that the thanks of this association be tendered to the mayor, simply.

Mr. Foote—Mr. President, I wish to explain why I offer the resolution. I want to get the address in full, in an authorized shape from this association, for a use which I think will meet the approval of every person here. In Mr. Hewitt's remarks about the importance of the re-distribution of power to the people, he expressed identically the same sentiments that I heard expressed within the last four weeks by the president of the Commercial Club of Cincinnati. About two weeks ago I was requested by an officer of one of the leading banks of Cincinnati to go with him to the exposition and show him the electrical exhibit there in its commercial relation. He brought with him an officer of the National Banking Association. The National Banking Association will hold their meeting in Cincinnati in October. Their question to me was : Will the stocks of electric companies become dividend paying stocks? That is the point they are looking after. Now, I wanted to get this paper in an authorized shape to distribute to the members of that National Banking Association. I believe there are some three thousand of them, and I am ready to give my personal order for 3,000 copies of the pamphlet if it is issued. I wish to say also that I would like to have the pamphlet prefaced by the address of our president in opening our sessions, showing the scope and the meaning and the importance of the electrical industry as it now stands.

Mr. Arthur Steuart, Baltimore—I want to add my approval to this resolution and my voice in favor of having the matter carried out. I listened with the utmost pleasure to the address of Mr. Hewitt yesterday, and I am sure that I express the feeling of every member of this association when I say that it is the very best presentation of the importance of this subject in which we are all interested that has ever been made. It is the most practical, sensible and intelligent presentation of this very difficult and much mooted question of what is to be done with the electric light wires that has ever been put before us or called to the attention of the public. Now, I know that it is so in our own town, and I feel that it is equally the case in almost every town in which our delegates live ; that the authorities are ignorantly striving to do just what Mayor Hewitt told us they had been striving to do in this town,—trying to put the electric light wires underground, without any knowledge whatever of the conditions necessary ; and I think that the address of Mayor Hewitt, coming as it does from a man who stands prominently before the people of this country, not only as the mayor of the greatest city in the land, but also as one of the recognized leaders of the best and most intelligent thought among the people, will go far to quiet the difficulties that all of us have met within the municipal bodies of our cities upon this subject. I therefore hope that the resolution will be adopted, and the address circulated as widely as possible.

The President—Are there any other remarks on the resolution? The scope of the resolution is that we take the address of Mayor Hewitt from the official notes of our own stenographer with the endorsement of this association, it being one of its official papers, and print it in pamphlet form so that the members of this association can have as many copies as they please for distribution.

The resolution was adopted.

Dr. Moses—It has been very properly suggested that the remarks of Mayor Hewitt yesterday, while being very commendable and beautiful, yet rested upon a foundation. That ought to appear too in the pamphlet, because he spoke at length of the progress of the industry which was so clearly set forth in the report of the president. Now, it would perhaps be a good idea to embody the two, since they had reference to the same subject. I would therefore make this motion : That the report of the president be added to this pamphlet which is to be published ; that is to say, that the report of the President and the address of Mayor Hewitt be printed in the same pamphlet for distribution.

It was voted to include president Duncan's address in the pamphlet.

Dr. Steuart made a motion that the chair appoint a committee of five to consider the recommendations of the president in his opening address, and report at this convention.

The motion was duly carried.

Dr. Schuyler S. Wheeler, of New York, then read a paper on "Overhead and Underground Wires in New York," as follows :—

OVERHEAD AND UNDERGROUND WIRES IN NEW YORK.

BY DR. SCHUYLER S. WHEELER.

Mr. Chairman and Gentlemen of the Convention :

It is my purpose, in as brief and concise a manner as possible, to give you some idea of the condition of the overhead and underground wires in the City of New York, and the means which are being adopted by the public authorities to bring about a better state of affairs than the one now and for some time existing.

In 1884, the Legislature of the State of New York enacted a law to the effect that electrical companies in the cities of New York and Brooklyn should place their conductors underground. The local authorities were expected to enforce this law, and the maintenance of electrical conductors overhead in these two cities after a certain day was declared to be unlawful.

Of course, the business of telephoning, telegraphing and electric lighting could not be disposed of so summarily, and before the day appointed upon which the maintenance of wires overhead was to become unlawful fell due, the Legislature enacted in 1885, a law providing for the establishment and organization of a commission, the purpose and object of which was to provide a plan by which electrical conduct

tors in the cities of New York and Brooklyn could be placed underground without interfering with the efficiency of the electrical service. By this law of 1885, it was provided that companies could submit to the commissions established in the twin cities, plans for placing their conductors underground, and should the said plans meet the approval of the commissioners, the companies submitting them could thereupon proceed to place their conductors underground according to these approved methods.

In 1885, the question of placing electrical conductors underground was very generally disputed, and no companies submitted plans to the commission within the required time. It thereupon became the duty of the commissioners of electrical subways to devise a method by which electrical conductors could be placed underground and to compel companies to carry out the work according to this method.

The subject was then comparatively new, the difficulty not fairly comprehended, and the different kinds of service, as well as the ways in which the wires might be put underground, were not even classified.

The result of the investigation made by the commission to ascertain by what method wires could best be placed underground in cities was that the commission had to listen to about 450 plans, many of them having nothing to do with the work to be accomplished, and many of them utterly absurd.

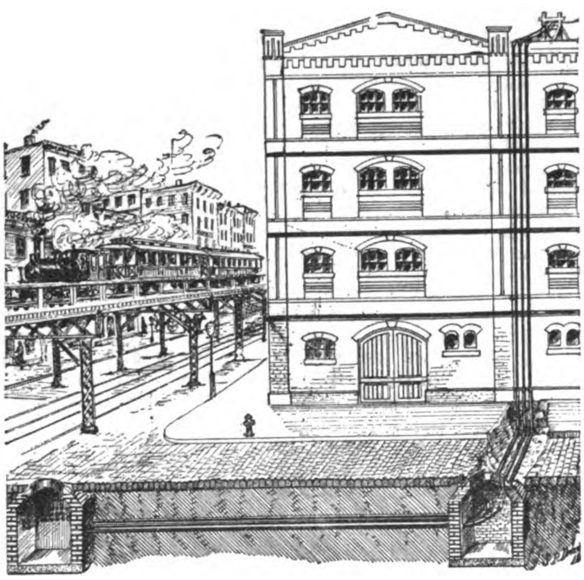

FIG. 1.—House-top Distribution, Sixth Avenue and Fifty-first Street, New York.

Notwithstanding the impression that underground wires were a common thing in other cities, especially abroad, nothing had been done that would serve as experience for this city. In many places wires had been laid underground singly, in pipes, in sewers and in cables; but no such piecemeal plan could be allowed in a city having more telephones, more telegraphs, more electric lights, and less available area, than any other spot in the world, in proportion to the amount of business going on. To be of any value, under such circumstances, a plan had to be found which would permit new wires being put in from time to time, almost without limit, without disturbing the pavements of streets, and of sufficient capacity to accommodate the large number of wires, for which a sufficient space underground could scarcely be found between the various obstructions already buried.

The difficulty of the problem, and the reason why the experience of other places are of so little value to us, will be seen when it is considered that the number of wires in a given space in New York, taking the average, is very much greater than in any other centre in the world.

The places between which these wires run, instead of being in an approximately circular area, as in the case of the three other leading electrical cities, are drawn out on a long and very narrow island, thus crowding the conductors together and increasing their length between points. In addition to the difficulty of a much greater amount of wire and less area to contain it, there is the great difference in rapidity of business, which makes it necessary to be able to put up and remove wires and instruments here more speedily than in the older cities.

The ground was so filled with gas, water and steam pipes, sewer and pneumatic despatch tubes, and their connecting boxes and man-holes, that it was impossible to find a straight course for a conduit or even a small number of ducts; and the repairs to these, which are continually going on, would make the wires specially liable to disturbance and injury. The earth is saturated with gases from the various pipes and this would collect in any open space, such as the subways would afford, destroying the insulation of the cables, suffocating the workmen, or causing explosions. In comparing wires with gas mains, it is sometimes said that the former are much more difficult to bury successfully than the latter, because the leakage does serious harm, while the leakage from the gas pipes is of no consequence. It is true that the loss from escaping gas does not cripple the gas companies' business, at their present prices, but the gas fills the earth, gets into the electrical conduits, and there makes a very bad combination, for which electricity has to stand the whole blame. Indeed, if it were not for the gas, the underground wire problem would be easier, and very much more agreeable. On the other hand, when the electric current wanders off and melts the iron of the gas pipe, electricity again has to stand the blame, and thus there is not a fair distribution of the responsibility.

In order to treat the subject thoroughly, the board of electrical subways, of the City of New York, investigated all the different systems in use in other cities; in connection with the many plans which were submitted for approval to be used in New York.

It was found that in Paris, they are fortunate in having extraordinarily large sewers, through which (in the streets where the sewers run) all of the wires are laid, together with the water pipes. These sewers consist of a large arched passage with a flat floor, through the centre of which runs a deep trench or canal for the sewage. The flat pavement on either side of this forms a broad walk, over which the pipes and wires are suspended from the arched roof. A rail is laid on either side of the canal, and on the track so formed a car can travel carrying a drag which is used in cleaning the canal or sewer proper. In the streets which do not have these sewers the wires are strung upon the housetops.

The only other place which at that time furnished experience at all applicable to the problem here was London. But here there were and are now, practically, no arc lights at all, and therefore no circuits; there are extremely few incandescents, with no out-door circuits; the telephone is not used very extensively, and the wires of the telegraph are placed underground by the government. The plan employed is what might be called the hand-hole "drawing-in" system, and consists of 5-inch cast-iron pipes laid under the sidewalks and accessible through hand-holes or "flush boxes." These pipes are said (I do not know how correctly) to be loosely jointed for the purpose of admitting water to preserve the cables, which are of gutta-percha, the same as is used for submarine cables, and which deteriorate very rapidly when exposed to the air. In other words, they have learned by their experience with ocean cables, how to make insulation which will stand the water, so they try to convert the subway problem into the same kind of work. Conduits have been laid at a later date in other places.

In Brooklyn there are about 10 miles of Dorsett conduit, and about four and a half miles of a conduit consisting of a wooden box made of creosoted boards loosely put together,

with narrower ones slid into grooves on the inside to form partitions. This duct, being loose and unstable, simply affords a means of keeping cables from touching each other and keeping them in place; and as creosote will dissolve rubber it is not a good place in which to put a rubber cable.

Another plan which has seen some slight use in Philadelphia is the Johnstone system. This consists of a broad, flat, cast iron duct, made in sections, about six feet long, and divided horizontally into an upper and a lower half or shell, so that a section can be removed and another substituted without cutting the wires already drawn into place. The duct is divided into a number of smaller ducts, for classifying the wires, by partitions consisting of long slabs of cast iron, which are slid into place in grooves cast in the inside of the outer shell. The feature of this system is the facility which it affords of introducing an outlet from the duct exactly opposite any lamp post or desired part of a building, by taking off the upper or lower half of a single section and putting in its place a new half section with a hole in it at the desired point, to which a branching elbow can be bolted.

This construction has been authorized for a distributing system in New York, on Broadway from 14th to 34th streets, for arc lighting, etc. The work is now being prepared, and the system is, therefore, of some interest.

There goes with this style of conduit a man-hole formed of a bottom, a top, and variable number of rings or sleeves placed upon each other so as to build up the height of the man-hole and permit of the ducts being run out at any depth to escape pipe obstructions, etc. One of these sleeves is split up into a number of panels bolted together, any one of which can be taken off to allow the ducts to be run out on either side at any angle.

All of the other plans by which wires have been put underground, except the Dorsett and other man-hole "drawing-in" systems used in this city, which will be described later, consist of nothing but the wire with covering buried in a trench, and are of no value beyond the taking care of their own particular wire.

Prominent among such plans may be mentioned the Edison tubes. This system, which has been extremely successful for its one kind of service, consists of heavy copper rods wound with rope, and laid in wrought iron pipes filled with an insulating compound composed of Trinidad asphaltum, rosin, paraffine and linseed oil. This compound is run into the pipe when heated to about 300 degrees Fahrenheit, under considerable pressure, while an exhaust is applied to the other end for the purpose of drawing out all air bubbles. The ends of the tubes are then plugged with wood soaked in paraffine, leaving the coppers projecting.

The chief peculiarity of this system of conductors, and the feature which is, perhaps, most familiar to all, is the means of connecting up these lengths of tubing and conductors. The rods are connected by short pieces of copper cable terminating in suitable copper sleeves, which are soldered to the ends of the rods when in position, and the bow-shaped expansion joint so formed is covered with hot compound poured into a small cast-iron coupling box, which is bolted on to the junction. The lines terminate at the street crossing in large cast-iron boxes, like man-holes, where the rods are joined by heavy copper cables to a suitable connecting device near the top.

This plan is too expensive except for very heavy conductors, but serves admirably the requirements of incandescent lighting. In the early days of the system the thin pipes were greatly damaged by picks in digging around them and by outside disturbances. A slight blow from a pick would puncture the pipe, letting in a little water, which was liable in time to form an arc between the conductors, which would in turn burn the compound converting it into a conductor, and forming a cross. The greatest difficulty with these tubes was found to be that the insulator would be converted into carbon by the charring action of leaks at the slightest start.

Tubes of the same style, but containing a large cable of small wires, have been in successful use in carrying telephone wires out from the Twenty-first street exchange in New York.

Another method somewhat similar is the Brooks' system, which consists of wires covered with cotton and drawn through large iron pipes, which are afterwards filled with a heavy rosin oil, so as to prevent the water from entering. This oil is a good insulator.

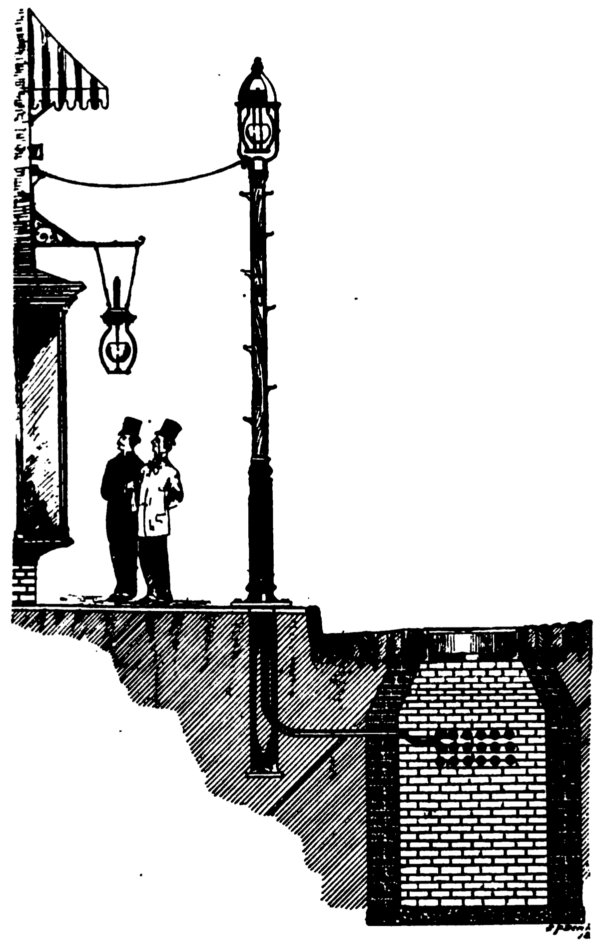

FIG. 2.—Lamp-post Approved by Board of Electrical Control. Manhole and Conduit for Electric Light.

The remaining plans are of a lower grade of mechanical construction, and consist of wires and cables of various kinds laid in troughs and covered with some protecting substance, usually tar or asphaltum.

Among these may be mentioned the few telephone and telegraph wires in Boston, made into a cable laid in a trough and covered with bitumen. A few telephone wires in New York and electric light wires in Pittsburgh are laid in the same way.

There are also innumerable places where cables of various kinds are laid directly in the earth, sometimes with a board covering to protect them from men with shovels. But none of these are of special interest to us, because, obviously, we cannot use them.

The result of the investigations of the commission were summed up in their second report, dated June 30, 1886, as follows:

"The principal systems of electrical subways may be divided, first, as to their material composition, and second, as to their mechanical construction, and the manner in which the wires are placed in them.

"As to material composition, subways are,

"1. Of insulating material, such as wood, glass, concrete, etc.

"2. Of conducting material, such as iron.

"As to mechanical construction, subways are, generally speaking,

"1. Tunnel systems.

"2. 'Drawing-in' systems.

"3. Solid systems.

"4. 'Dropping-in' systems.

"5. Combined systems.

"Tunnel systems, or those where space is provided underground sufficient to allow the passage to and fro of men who place the wires within the subway, could be recommended, were unlimited time and money at the disposal of the commission; but the expense of such a system and the crying need of immediate action preclude the adoption of such a plan. If ever underground railroads become a feature of our city transportation then, perhaps, the tunnel can be used for some of the future trunk line cables.

"In Paris, where the foundations of the city are honeycombed in all directions by large sewers, such a plan is practicable and admirable, but not to be thought of in New York.

"Drawing-in systems, or those where man-holes are provided in the streets, connected by tubes or pipes, through which the wires can be drawn, are next in prominence and convenience to tunnel systems.

"In Chicago there were seen in successful operation nearly twenty miles of conduits of the 'drawing-in and out' pattern of various materials, containing all kinds of wires, as follows:—

"Eight miles of the Dorsett system of concrete conduit divided into ducts, and containing in the separate ducts wires of the city telephone, telegraph and fire service, electric light wires and wires of different telegraph companies.

"Four miles of the Johnstone system of iron conduit divided by metal shelves, and carrying the wires of the Postal Telegraph Co.

"One mile of 3-in. iron pipes, four in number, carrying the wires of the Western Union Telegraph Co.

"Three miles of iron pipes, carrying the wires of the Bankers and Merchants' Telegraph Co.

"In Philadelphia, a comprehensive 'drawing-in' system of iron was seen, containing electric light and telephone and telegraph wires.

"In Boston some two miles of such 'drawing-in' iron systems are in operation.

"In London 9,000 miles of wire are underground, bunched into cables and drawn into 3-inch iron pipes.

"Solid systems, or those where wires are permanently embedded in insulating material and incapable of being reached except by tearing up the streets and the insulation, have been found to work with more or less success. The commissioners saw several miles of this conduit in successful operation in Chicago by the telephone company there, where wires were buried in an asphalt or coal-tar cement, laid in a wooden trough.

"Several miles of similar conduit are in use in Washington for electric lighting, and there are other instances of the successful operation of this description of conduit.

"In this city of New York there are several systems in use underground, each more or less satisfactory to those employing it.

"A prominent example is the Brooks' system, used by the Metropolitan Telephone and Telegraph Co. It consists of an iron tube in which cotton-wrapped wires are drawn, and the tube filled with oil, the oil acting as an insulating medium. It is kept at a desired pressure—the tubes constantly full by means of a stand-pipe. They use a 2½ inch iron pipe, and the system is cheap, costing less than $11 per mile of wire, because into such a pipe they can draw 300 telephone wires. Wires for telephone purposes, and those used in the American District and other call boxes, are of a very light intensity, and do not need as heavy insulation as do all other kinds. This system is claimed to give perfect satisfaction for telephone conductors.

"The Western Union Telegraph Co. has many wires already down in this city, laid in 3-inch iron pipes, into which they draw cables manufactured from okonite or kerite insulation. These pipes are lead jointed, are laid in Broadway, and have man-holes occasionally for taking out the wire.

"To sum up as to the form of subway, and the manner in which the wires are to be placed in it:—

"We are convinced that from the standpoint of an electrician simply, it may be said that almost any plan or system can be *made* to work, from a single lead covered wire laid directly in the earth to a great tunnel upon whose walls the insulated conductors can be hung. Within certain broad limits any system is electrically practicable; retardation and induction can be overcome. It is only when we face in this city the mechanical engineering and chemical questions of interference with water pipes, gas pipes and sewer pipes, of obstructions from vaults, or danger from steam pipes, of the action of sewer and illuminating gas, that the necessity for careful discrimination presents itself.

"In the future, when the uses of electricity become more general, and its nature better known, it may be that the City of New York will absolutely require a grand electrical underground highway, where space can be provided for the conducting and distributing of sufficient power to run all the engines and work all the machinery within the city limits. It may be, and probably will be, that before such space is needed much more will be known of the qualities of different forms of electrical conductors, and of the best method of carrying them underground, and that the matter of electrical subways will be no longer experimental, but practically demonstrated in every detail.

"When such a time comes the commission or other authority will determine what is required to meet the necessities of the occasion.

"The responsibilities of the present commission begin and end with providing for the requirements of their own day, and for such of the exigencies of the future as they can reasonably anticipate.

"Leaving out of consideration all tunnel systems as too expensive, we must also discard any system which calls for the simple laying of insulated cables in the earth. They would not stand the chemical action of the gases and acids; the streets would be continually torn up for new connections and repairs. We are thus shut up to the question of electric subways or conduits, in which the wires or cables, insulated or otherwise, must be placed, and which once laid down should meet all the demands of the present and near future.

"Of conduits it may be safely predicted that, so far as the experience of this and other cities is a test, some form or other of a 'drawing-in' system is most convenient. The life of the best cable is by no means satisfactorily decided, and, of any particular cable, to predict how long it would last would be purely speculative. Of wires not contained in cables it may be said that they are equally or more uncertain in their length of life and usefulness. At all events, for purposes of distribution it is desirable that the wires should be easily approached at frequent intervals, and the commission cannot countenance any plan that looks to the disturbance of pavements more than is absolutely necessary.

"It may be that through lines of wire could be better protected laid in permanent beds of insulating material; but a 'drawing-in' conduit system allows space to be provided for new wires without the frequent tearing up of pavements.

"The commission can, therefore, give their approval to a 'drawing-in' system with frequent man-holes, as the

general form of subway best adapted to meet the requirements of the electrical service of the present."

Up to this time it was the general impression which had not been contradicted by experience, because there was none, that the conduits must be built of a non-conducting substance, and not of metal, because the latter would be liable to chafe through the insulation on the wire and cause a ground, and because the companies using the more delicate currents—particularly the telephone company, declared positively that the presence of the large mass of surrounding metal would interfere by induction with the working of their wires.

The best known plan at this time for building ducts of insulating material, and without the use of metallic tubes, was the Dorsett system, which had been laid to some extent in Chicago.

This consists of a bundle of parallel tubular ducts about two and a half inches in diameter, built of blocks formed of a combination of coal tar, pitch and fine gravel, cast with tubular openings running through them from end to end. These blocks were placed together, end to end, with the holes in line so as to form continuous tubes or passages, and were cemented together by pouring a mastic, softer than was used in making the blocks, into the cracks between them. The blocks were made to adhere to this by warming their ends with hot irons and allowing them to cool after the mastic was poured in. To prevent the melted mastic from closing the ends of the passages, tubular pieces of metal or paper were inserted in the ducts at the ends of the blocks, making a sort of internal sleeve coupling. The conduits so formed terminate in brick man-holes at the street crossings.

The objections to this material, as it was afterwards found, are that it is brittle, porous, requires care in laying, and, having no elasticity, cracks with changes of temperature, so that it is not likely to be made water-tight with average workmanship.

But a conduit was laid in New York according to this plan, on 6th avenue, from 23d to 58th streets, a distance of 1.6 miles. And the objections were then found, as far as arc circuits were concerned, that its numerous joints were liable to open, and it might leak as indicated above.

The next plan proposed for New York was to use a somewhat similar mixture without requiring it to be made so hard, with the object of preventing its cracking, and to preserve the openings or ducts by casting this bituminous mastic, or mixture of bitumen and sand, around long pasteboard tubes. But no tubes could be found which would not absorb moisture, and the heat of the mastic caused the tubes tried to swell up and disintegrate. The manufacturers of indurated fibre wares, were confident that satisfactory tubes could be produced, but it required special machinery and a long time for experiments. Tin and sheet iron linings were then suggested, but objected to, on account of the difficulty of making good joints. Zinc, however, was considered unobjectionable, and an experimental duct of the Averil system, consisting of soldered zinc tubes in bituminous mastic was laid in the yard of one of the manufacturers; but it was found that the heat of the mastic melted the solder of the tubes. This difficulty was met by substituting a lap or fold over-seam, and then it was found that the heat of the mastic also affected the nature of the zinc, impairing its durability. On account of the certainty of the zinc tubing rusting and finally crumbling away, it was next thought best to insure the permanence of the bore of the ducts by substituting for the soft mastic some substance which would set, after being poured in, and become hard and durable. For this purpose a hydraulic cement concrete filling was substituted for the mastic. And then a line was laid in 58th street. In laying, the thin zinc tubing was found very frail, liable to be dented in handling, and therefore undesirable. But it was thought that the concrete would maintain a hard solid, smooth bore, even after the thin sheet metal lining had rusted out.

After a thorough investigation and discussion of all the different materials, and the advantages and disadvantages of each, it was finally concluded that a conduit or subway for electrical conductors, was merely a mechanical protection for the wires to be placed therein and should afford the very best protection possible to be procured, while the electrical protection or insulation might safely be left to the manufacturers of cables and wires to be placed in subways.

It was decided that the use of metallic tubes would not seriously interfere, by induction, with the working of the wires, and were to be preferred because the continuous conducting shield so formed will carry off any escaping current and prevent damage to other cables. Accordingly, conduits of iron gas pipe embedded in concrete were put down, and these seem to be about the best kind so far constructed. They are best, first because there are plenty of workmen who understand gas pipe fitting and laying concrete, and because they are durable and entirely non-combustible. The purpose of the cement is to prevent the iron from rusting, which it does very effectually. If in time the pipes are destroyed by rusting from the inside, the solid hydraulic cement concrete will remain, furnishing a permanent duct with a hard smooth bore.

The man-holes used in connection with these various kinds of ducts have nearly all been built of brick laid in hydraulic cement, and capped with an iron casting to form a seat for the water-tight lid. The lids are bolted down upon a rubber gasket; but, unlike the Edison lids—held by several screws—they are secured by a single thrusting screw, which, passing through a cross-bar presses down upon the centre of the cover. Some of the lids have been made funnel-shaped, so as to cause water to drain away from the edge and collect in the centre. By this means, the liability to leakage at the gasket is diminished, because there is less chance of water standing over the joint. The facility of opening the man-holes afforded by this method of fastening the lid with a single screw, is of great value in reducing the labor and time required to open and close a line of conduit when laying a wire, and is a material advance in the solution of the problem.

In regard to moisture in the conduits: in the iron tube plan which is the best, there is of course no leakage, because the tubes themselves are water-tight, could even be made air-tight, and because they are covered with cement which is in itself water-tight. The man-holes are made of water-tight materials, and there should be no leakage under the lid. Lookers-on find that a great many of the man-holes have a great deal of water standing in them; this is simply because the lids are not fastened down, but simply laid in place by the builders, often without any gasket, and the man-holes fill with rain and stay full until cleaned out for use. When cleaned and closed properly, they appear not to receive any water by leakage. To satisfy myself of this, I had an ordinary brick man-hole, which had been thoroughly cleaned and dried by letting the sunshine in, on a bright day, marked on the inside with lime all the way round under the cover and then closed. This marking was to show whether any water came through the joint of the cover, in which case it would have run down over the lime mark and discolored it, or whether it soaked in through the bottom or sides. But after a rainfall sufficiently heavy to test the leakage, the hole was opened and found perfectly dry and the lime undisturbed. This proved that there was leakage neither through the brickwork nor under the cover.

There is, however, another source of moisture, difficult to overcome, viz.: the condensation of vapor from the air which the man-hole and ducts contain. Every time a hole is opened, it refills itself with warm air, containing more moisture than it can keep when cooled down to the temperature of the masonry; consequently as soon as the

lid is screwed down, this fresh air deposits a dew on the inside of the man-hole. As it is impossible to open and dry out a man-hole without letting in new air which will condense in turn, no amount of cleaning will overcome this difficulty. The presence of moisture tends to corrode exposed wires; and, therefore, the question of whether it is better to protect the splices and make the insulation of the wires so that they will not be injured by this moisture, or to dry out the entire system of conduits by a system of ventilation is unsettled. But this question fortunately is one of minor importance.

The question of distribution of electrical currents from the main subways constructed in the manner I have described, has been largely left by the authorities in the City of New York to the preference of the electrical companies.

Two systems of distribution are at present actually in use in New York by the telephone company. These are known as the house-top system of distribution, an example of which may be seen at Sixth avenue and 51st street, and the hand-hole system of distribution, which may be seen at Broadway and Exchange place.

In addition to these systems, there are five modes of distribution which can be readily applied to the subways as constructed in New York, and which will be allowed in cases where they are severally most expedient,—the lamp-post system of distribution, the house-front system, the house-vault system, now in use in Chicago, the back-yard system, and the man-hole system. In the heart of Chicago, the distribution question is peculiarly easy of solution, because the sidewalks were left hollow by raising the street levels after the great fire, and the wires are run through these spaces to the houses.

Having decided the question of the kind of conduit to use, the commission proceeded to have subways constructed accordingly at once. It was decided best, as a matter of expediency and to prevent accident, that electric light subways should be distinct from those intended for telephone and telegraph service, and it has therefore been the practice of the authorities in New York to build subways for one class of conductors upon one side of the street and reserve the other side for the other class.

The telephone people were the first to realize that underground wires were sure to be, ultimately, a success. Their business had grown enormously, they had about reached the capacity of their poles lines, and it was not easy to get the use of additional streets, because the streets were crowded with wires,—both their own and those of other companies. It was found that the growth of the telephone business was practically put an end to, by the fact that no more room could be found in which to string wires. House owners were charging a rental of one dollar per wire per year, which, in some cases, amounted to a very large rental for a single building, and the telephone people had reached the point of refusing subscribers. They then came forward, and were the first to declare for underground wires.

After some resistance, the telegraph and electric light companies have come to the conclusion that it is as well for them to comply with the demands of the public and place the bulk of their conductors underground. And, as a matter of fact, in the City of New York, to-day, there is but one single company out of the large number doing business here which refuses absolutely to comply with the provisions of the sub-way acts, and nine-tenths of the opposition and outcry has been caused by that company.

At the present time the total construction of single ducts in the City of New York amounts to four hundred and twenty miles. In these subways, there are already in operation some four thousand miles of telephone and telegraph wires, and some hundreds of miles of incandescent electric light conductors. Cables for arc lighting are to be drawn in on Broadway from 14th to 34th streets, by the Brush Electric Lighting Co. within the present week. A letter from the electrician of the Metropolitan Telephone and Telegraph Co., bearing date August 25th, as estimating the length of cables of various kinds now underground, is as follows:—

New York, August 25th, 1888.

S. S. Wheeler, Esq.,
Electrician of the Board of Electrical Control.

Dear Sir:—I have hastily collected the following information relating to the underground mileage of wire:—

The number of miles of single wire conductors in New York city of the various kinds is as follows:—

Brooks' system, laid May 28th, 1885	200 miles
Patterson cable, laid March 18th, 1885	226 "
Edison system, laid June 20th, 1885	194 "
Patterson cable, laid in 1886-87	805 "
Patterson cable, twisted in pairs, number of miles counting both wires, in 1888	2,272 "

We have in course of construction some 12,000 miles of conductors which will be laid in September and October.

Total number of miles already laid in New York, 3,697.

The number of miles of underground wire in Brooklyn is 2,100. The number of miles of underground wire in Paris is 4,100. The number of miles of underground wire in Chicago is 200.

As per report of telephone convention held September 26th, 1887.

The number of miles of underground wire in Boston is 400. The number of miles of underground wire in Pittsburgh is about 1,000.

I find that there is a very small amount of underground wires used in London for telephone purposes, there being some short lengths used entering exchanges, which is not worth while considering. Respectfully,

(Signed) J. A. Seely, Electrician.

It will be seen from this that there are already underground in the City of New York more electrical conductors than in any other city in the world (except Paris), while the capacity of the construction already finished in this city may be estimated fairly at something over thirty thousand miles of conductors.

There are through lines completed from the Battery to the Park on the two principal thoroughfares of this city, Broadway and Sixth avenue, and a gradual conversion of overhead lines to underground lines in the busy parts of the city may be confidently expected.

The board of electrical control is not unmindful, however, of the magnitude of the labor and expense required in converting the present arrangements into underground systems, and does not contemplate either the hampering of the business of electrical companies by forcing unreasonable numbers of wires underground, or by attempting to compel the use of subways faster than is consistent with the efficiency of the various electric service to the public. If the great mass of overhead conductors are removed, and the remainder of the service brought to a condition which will insure the safety of the public, and, at the same time, the benefit of the companies themselves, it will be the result desired by the people of the city, and which the board of electrical control is endeavoring to attain.

As to this matter of regulating the overhead service in the city, I may say that an investigation of all the wires overhead, instituted since I have been connected with the work of the authorities in charge of electrical matters here, by the inspectors appointed after a rigid examination and found competent for the purpose, has shown that a great deal of very bad and unnecessarily dangerous work has been done in New York, and that a reprehensible and inexcusable condition of overhead wires is the principal, if not the only, cause of the clamor for underground service.

In addition to this, an enormous quantity of wire and a large number of poles not in use at all exist, amounting, as

has been variously estimated, to from a half to two-thirds of all the wire and poles in the city.

As I have said, a system of inspection and reports has been organized, and within a few months there have been found and reported to the owners 2,000 dead wires and other objectionable things described in the enclosed schedule, which explains itself. A notice is sent out in every case; at the end of a week the work is again inspected, and if nothing has been done the owner is again notified, and if the wires, poles, etc., are not necessary, a notice is also sent to the Bureau of Encumbrances of the Department of Public Works to remove them.

All arc lamps that are so low as to be within the reach of a pedestrian with an umbrella are reported as too low. Circuits which have especially defective insulation or joints are reported as dangerous. A few cases of bad indoor work have been reported as violating the rules of the board of fire underwriters, and so on. The number of complaints sent to the various companies, as well as the proportion of them that receive attention by each company, are shown in the detailed schedule, which indicates the position taken toward the work of inspection by the several companies, and I may say that the contumacious company of which I have already spoken, is the only one which disregards the notification of flagrant bad work, for which there is no excuse, and which everyone else admits should be inspected on behalf of the public and corrected immediately.

One has no idea of the aerial freebooting that is and always has been going on with overhead wires, until he spends some time seeing what there is overhead. The condition of wires in this city is simply outrageous. Every other kind of business, such as those which involve obstructing the sidewalks, have fallen under the supervision of some branch of the government, and cleanliness and order have been insisted upon; but heretofore there has never been any supervision of out-door wiring, and its condition corresponds to that of a city without police supervision.

The companies owning wires will not permit each other to make common use of the poles, but will chop off wires owned by others without notice. The telephone people object to the electric light wires on account of the induction. Where there is a line of light wires on their side of the street passing close to their poles they will not allow them to be made fast. The result of the necessity thus made for extra poles is sometimes four lines of poles on one side of the street, hence most of the wires swing close to or against the other poles to which they are not attached, and linemen in climbing them have to crawl through all the other wires which are not fastened to cross-arms.

Among the cases of dangerous wires and unnecessary obstructions found by the inspectors, are full lines of large poles extending over miles of streets, filled with wires which are "open" and out of use, but left standing to save the expense of removal; long lines of poles left standing to preserve right of way; arc light day circuits within reach and with the insulation dropping off, and bunches of dead wires hanging from house tops, etc.

All of the work of inspection done by this department is such as is necessary for improving the condition of overhead electrical work and removing fixtures, etc., that are absolutely dangerous and objectionable.

For the purpose of the various legal proceedings which are being carried on to compel the most objectionable arc light company to make a start in placing their wires underground, the other principal companies having proceeded voluntarily, the pole line on 25th street from Broadway to Fifth avenue was chosen for special complaint. The subways on this route which were specially provided for these lines have been finished for some time, and are dry and in good order. This line of overhead wires is in bad order, one of its stretches having no less than thirteen splices; and it is made still more liable to do damage by the presence of numerous dead wires which, not being required for use, are practically stored upon the cross-arms.

REPORT OF ELECTRICAL EXPERT OF THE BOARD OF ELECTRICAL CONTROL.—DETAIL OF ALL NOTICES OF VIOLATIONS OF RULES AND REGULATIONS SENT, FROM JUNE 14 TO AUGUST 24, 1888.

In conclusion, we may sum up the situation about as follows:—

The telegraph and telephone problem is practically

solved. It is found necessary to resort to subways in order to get sufficient space for wires, and wires for this use are being drawn into the tubes as fast as the labor can be performed. There are about 4,000 miles of telephone and telegraph wire already underground, and 12,000 miles of cables about to be laid in the fall. It is estimated that the saving in cost of maintenance will be about $100,000 per year owing to the permanence of the kind of work which is possible underground.

The laying of electric light wires has not been so fully developed, and naturally none of the companies care to bear the expense of the first experiment. But after the initiative has been taken the difficulties will be overcome as they arise, as in the development of all other enterprises, and the underground system will become a settled and accepted fact.

Meanwhile, the lawless running of overhead wires is being stopped. All wires in a street must be run on a single line of poles. The dead wires and poles must not be stored in the streets, and all construction must be made under the supervision and control of some official in precisely the same way that other works which affect the public are carried on.

The President—If any gentleman wishes to ask Mr. Wheeler any questions on the subject he has discussed in his paper, it might be well to put them now before they slip from mind.

Mr. E. T. Lynch, Jr., New York—I would like to ask Mr. Wheeler the estimated cost of laying these conduits.

Dr. Wheeler—I am not very well prepared to give the cost, but if Mr. Leslie, the manager of the construction company, who is present, will do so, I think he can probably answer Mr. Lynch's inquiry.

Mr. E. A. Leslie, New York—I do not think it will be possible to give an intelligent reply to that question, because the cost of construction varies very much, as the circumstances vary. In some cases the engineering difficulties are easily overcome, while in other cases they are very difficult indeed. Then again, the character of the excavation has a very great deal to do with it. It is a hard matter to say what the cost would be, unless the number of conduits and the side conduits, and so on, are specified.

Mr. Morris—Dr. Wheeler spoke of there being 9,000 miles of underground wires in the City of London. I would like to ask him whether those are high tension wires, and also as to what was the efficiency of the service.

Dr. Wheeler—I have stated already in the paper that there were practically no high tension currents in London, and that the wires put underground were put there by the government.

Mr. Lynch—Dr. Wheeler stated also that there was a conduit in 25th street. I would like to know if any means have been devised for getting the wires from the poles into those conduits, or whether any supplementary conduits have been provided by which the wires could be run to customers living in the block.

Dr. Wheeler—I also stated that the Johnstone company's conduit had been authorized as a distributing system to be laid on Broadway, and that it could be used in 25th street, but that the choice of a distributing system was left to the companies, and if they could find a better system why, of course, they could use it. It does not seem to me very difficult to get wires from a man-hole to a pole There are several hundred of them at the corner of 23d street and Broadway—telephone wires, coming up in tubes from the man-hole and going out on the poles. The same thing exactly can be done with the electric light wires. The question that is most difficult to answer is how to distribute them cheaply to each house; not how to get them out of a man-hole.

Mr. Lynch—Can the gentleman tell me if any practical trial has ever been made of the Johnstone system for electric lighting wires?

Dr. Wheeler—I am not informed as to that. I understood Mr. Johnstone was to be here himself.

Mr. DeCamp—I will say in regard to the Johnstone conduits—I presume these are the same that are used in Philadelphia—that it is a very good form of conduit. It is expensive, but I believe it is perhaps the best conduit we have. I am free to say, at any rate, that it is the best form of conduit that has ever been brought to my attention; but we have never got anything to put into it yet that answers the purpose.

Mr. Lynch—As I understand it, the subway company which lays down the conduit charges a rental for its use, and the company whose wires are to be put into it are supposed to make an arrangement with the subway company to put down supplemental conduits and connect the wires therein. Now I want to find out if the electric light companies are responsible for all work of that kind—if they are directly responsible for the wires and the supplementary conduits?

Dr. Wheeler—I think that question had better be referred to Mr. Leslie, who represents the conduit company.

Mr. Leslie—I do not see wherein the question of responsibility is important in the question of the practicability of operating electric light current. I will say that the company that Mr. Lynch represents has been furnished with information on all those points.

Mr. Lynch—I do not appear here as representing any company. My connection with the U. S. Illuminating Co. was broken off some time ago. I appear here asking for information as a member of this association. Now, as I understand it, the subway commissioners say: Here is a system which we think the electric light companies should put down and should be responsible for, besides paying for it.

Mr. Leslie—I believe Mr. Wheeler represents the subway commissioners. You had better ask him that question.

The President—Gentlemen, this is getting off from the main point, and we are getting into the general topic. The chair will have to stop this discussion at this point and ask these gentlemen to be present this afternoon, because it is very evident there are going to be several questions that will have to be answered.

We will now take up the next paper.

Mr. E. G. Acheson then read the following paper:—

DISRUPTIVE DISCHARGES AND THEIR RELATION TO UNDERGROUND CABLES.

BY E. G. ACHESON.

From among the numerous problems that are earnestly calling for solutions before perfection can be claimed in underground systems of electrical distribution for arc lighting, I selected, as the one presenting probably the greatest importance, and, consequently, the one most desirable to solve; *the determination of the cause and cure of the frequent puncturing of the insulation, especially at the terminals, of lead encased conductors, when carrying high potential currents.*

In a communication to the electrical press, published July 7th, 1888, under the title "The Influence of the Condenser on Disruptive Discharges," a detailed description of a series of experiments on the discharge between points in air was given; they having been made with varying E. M. F's. and condenser capacities.

These experiments resulted in the formulation of the general law expressed in the equation,

$$\frac{(\text{E. M. F.})^2 \text{ charge in coulombs}}{a} = d$$

or

$$\frac{(\text{E. M. F.})^3 \text{ capacity}}{a} = d$$

where a is a constant for the dielectric and d is the spark length; the charge being expressed in coulombs and the capacity in farads. In the same article the value of a was taken as 135 and d was expressed in inches.

While these experiments may serve as a basis or foundation to build upon, much more must be known before they will meet the requirements of the engineer operating with high potential currents, and with the object in view of obtaining, at least a small portion of this required information, my experiments were extended into the more practical part of the subject, and furnished the results I have embodied in this paper.

The most probable condition of a discharge in a cable would be between the cylindrical conductor and a point or projection on the lead covering, hence the first point to determine was the striking distance between such a cylindrical body and a projection or point.

Experiments were made with a point and the side of a wire, two sizes of the latter being used, a No. 8 and a No. 16 B. & S. wire gauge. There was no difference between the results obtained with the two sizes. The length of the spark was found to be about 55 per cent. when compared with that produced between points with the same E. M. F. and capacity.

This difference gives a new value for the constant a, which is found to be 263.

The equation for a spark length between a point and a cylinder will, therefore, be,

$$\frac{(\text{E. M. F.})^2 \text{ capacity}}{263} = d \text{ in inches.}$$

The following approximate values of a have been determined, for the conditions and dielectric specified, d being expressed in inches.

Dielectric.	Spark between.	a.
Air.	Points.	135
Air.	Point and wire.	263
Paraffine and cotton.	Point and wire.	5,822
Ozite and cotton.	Point and wire.	7,759

The conditions governing the possible disruptive discharge, through the insulation of the lead-covered, grounded cable, are so numerous that it would be quite impossible to exhaustively consider them, even if the necessary data were at hand, within the limits of this paper. It will therefore, be necessary to confine the subject to the more important conditions, and the exposition of the law by means of a case that might be found in practical work.

In figure 1′, is illustrated a portion of an arc light circuit, consisting of the dynamo D, and 30 lamps, L, connected in series by a lead covered underground cable. For the purpose of illustration and calculation, it is assumed that the lamps are separated a uniform distance of 300 feet; the size of the conductor, a No. 4 B. & S. wire gauge, insulated with one-tenth of an inch of cotton and paraffine; the capacity per mile is 0.704 of a microfarad, and the E. M. F. at the brushes of the dynamo 1,500 volts. Also, as an assistance in calculation, it is supposed that the drop in the E. M. F. occurs in the lamps only.

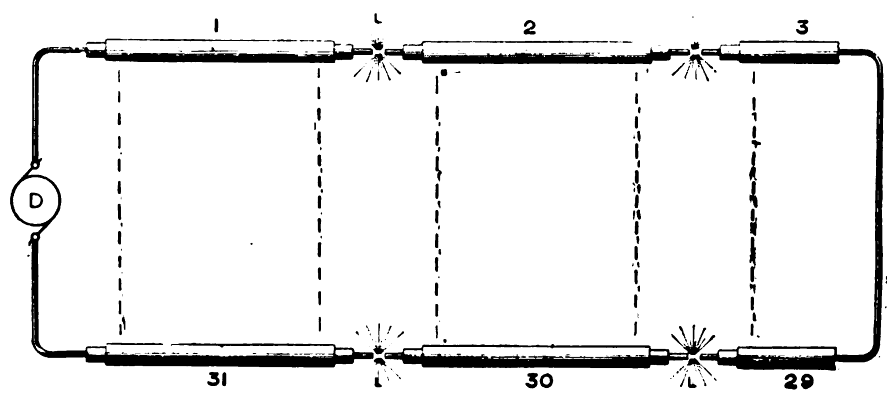

FIGURE 1

The capacity of each one of the 31 sections of cable separating the lamps and dynamo, and which are numbered in regular order from 1 to 31, will be 0.04 of a microfarad, and the capacity of each division, from conductor to conductor across the circuit, as between sections 2–30 will be,

$$\frac{.04 \times .04}{.04 + .04} = .02 \text{ microfarad}$$

or in this case one-half that of one side.

With these conditions each division, composed of the paired sections as 1–31, 2–30, 3–29, and so on, will have a potential tending to break through the insulation to the lead and thence across the intervening medium in the direction of the broken lines, of a value of 1,500 volts at 1–31 and decreasing by 100 volts for each succeeding division.

These various potentials, will, provided the insulation is perfect and the leads well grounded, induce a static charge between the conductor and the lead of each section, of a value measured by the potential across the division, and the specific inductive capacity and thickness of the insulating material.

In the case under consideration, the thickness of the insulation and the specific inductive capacity are such as to induce a condenser capacity of .02 of a microfarad, and with an E. M. F. of 1,400 volts as would exist between 2–30, the discharge would be, 1,400 × .02 microfarad = .000028 of a coulomb; and if the conductors forming the two sides of this division, should while in this charged state be insulated from each other, as might be done by breaking the electrical continuity at both ends of either one of the sides, the energy stored within it would be able to produce a disruptive charge through air, from the conductors to a point, or *vice versa*, equal to

$$\frac{(1{,}400)^2 \; .000028}{263} = .2087 \text{ inch.}$$

This is almost two and a tenth times the thickness of the insulation; but the thickness of cotton and paraffine, composing the insulation of the cable, that this energy would pierce, would be:

$$\frac{(1{,}400)^2 \; .000028}{5{,}822} = .0094 \text{ inch,}$$

or less than one-tenth of the thickness of the insulation.

Two questions now present themselves: First, are the sides of division 2–30, or any of the others, liable to become insulated from each other, or attain a condition favorable for a discharge, for will there not always be a path open for discharge around the circuit, either by way of the lamps or the dynamo? The second question may be stated thus: Is it probable, with the conditions of the case above taken, that the insulation will ever be pierced, seeing that the discharge through the insulating medium cannot be greater than .0094 of an inch, whereas the thickness of the insulation is 0.1 of an inch?

It is evident that from accidental causes, such as the breaking of the circuit at two points, it is possible to have the two sides of the division, insulated from each other; but such accidents are not liable to occur, especially when it is remembered that the breaks would have to be made simultaneously. To make the probability of this action occurring worthy of consideration, other means of producing it must be looked for and found.

On a circuit using coils shunted around the arc, the electrical continuity is established at each end of the two sides of the division, by one of these coils and the arc.

From the experiments of various experimenters, prominent among whom may be mentioned Professor Hughes and Dr. Oliver Lodge, it is concluded that the self-induction in these coils would be of such a value as to offer an almost insurmountable barrier to the flow of the charge through them; and this being the case, the discharge if it occurs at all must be through either the arc or the insulation of the cable. To determine whether the charge would pass off through the arc, the apparatus shown in figure 2, was used. Twenty incandescent lamps, L, of 100 volts each were connected in series to the lines M, N; in the line N, was placed the switch S, and the contact points 1 and 2, the former being mounted in the revolving post P, thereby permitting of the points being opened; the condenser K,

was connected across the circuit from the line M, to a point, 3, between the switch and the contact points, on the line N; around the condenser were placed the points 4 and 5, with suitable means of regulating the distance between them. M and N were connected to the two sides of a transformer supplying an E. M. F. of 2,067 volts. The points 1 and 2 being in contact no amount of rupturing of the circuit at S, and adjusting of the space separating 4 and 5, would cause a discharge to occur between them; but upon opening the points 1 and 2, and thus establishing an arc in the circuit, the opening of the switch S, would cause a heavy discharge between 4 and 5.

From this experiment and Dr. Lodge's results with circuits containing self-induction, the conclusion must be drawn, that conditions favorable to a disruptive discharge are exceedingly likely to occur, that upon opening an arc light circuit the various sections of the cable become, so far as the static charge is concerned, insulated from each other.

In considering the second question the fact is at once recognized, that where the constant *a* for the dielectic surrounding the conductor is that of the cotton and the paraffine a disruptive discharge would, under the circumstances cited, be impossible; and the answering of the question in the affirmative will therefore turn upon the probable lowering of the value of *a*.

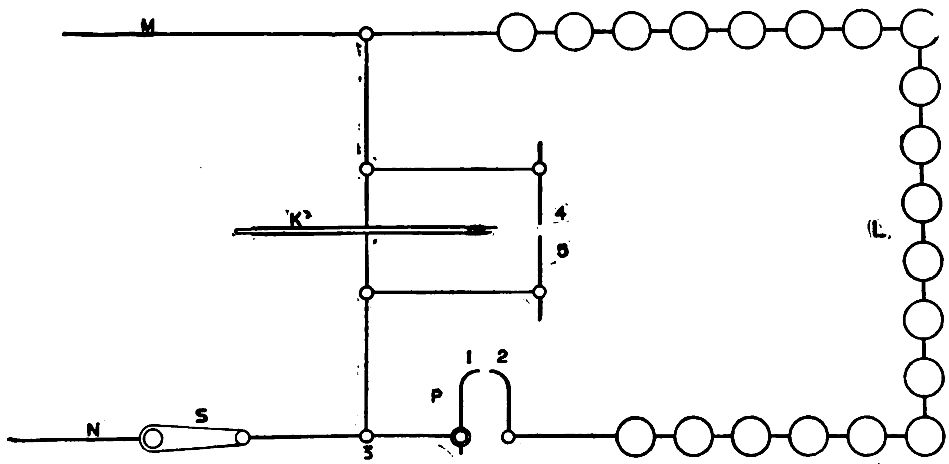

FIGURE 2

Any one familiar with insulations as applied to conductors, knows that all of them, with the exception of rubber and gutta-percha and their compounds, will permit water or moisture to penetrate them, and as the hydro-carbons and water do not form chemical compounds, the one being insoluble in the other, this passage of the water must be a purely mechanical action, and furthermore, openings, cracks, or crevices must exist in order to permit of its passage. In many cases the cracks are visible to the eye, while in others they can only be detected by submerging the insulated conductor in water for a time and then testing electrically. But even after proving the existence of these cracks, it remains to be determined that the static charge will be influenced by them.

As one means of testing the case, a plate of glass .072 of an inch thick was broken into two pieces and the two parts immediately fitted into their former positions and held together by clamps. The crevice or space separating the parts, was infinitesimal in width, as will be evident to anyone who may have made a similar experiment. The restored plate was placed between two discharge points, in such a position that the line joining the points passed through solid glass. Under these conditions I was not able with my facilities to cause a disruptive discharge to take place through the plate; but on moving it so that the line joining the points would lay in the plane of the fracture, a disruptive discharge occurred with an E. M. F. of 2,067 volts and a capacity in the circuit of .003.22 of a microfarad.

While this demonstrates the minuteness of the path required for a discharge, it is hardly a parallel case to what would exist in an insulated conductor, where the insulation was built up out of many overlapping windings of fibrous material and then treated with an insulating compound, for in this case the cracks or crevices produced by temperature variations and the bending incident to handling and laying of the conductors will not be direct lines or planes from the conductor to the metallic casing, but angle or zigzag lines, following the interstices of the fibrous structure; this difference would result in the lengthening of the path of discharge, but, scarcely to an extent sufficient to raise the resistance to discharge to the value of the insulating material in a perfect state; and so long as the value is below that of the insulating material, the value of the constant *a* is also lowered, and it is, therefore, reasonable to assume that the conditions may become such as to warrant an affirmative answer to the second question.

Unfortunately both of the two grand divisions of conductor insulators, the fibrous and non fibrous, have their faults, for while the fibrous has the, in some circumstances, serious fault of cracking, the non-fibrous has the even greater fault of losing its insulating qualities and running off the conductor, when heated, as might occur by an accidental overloading of a circuit; and when it is confined, as in a lead covering, it permits the conductor to become decentralized, and eventually come in contact with the lead casing. Between the two insulators, with the faults specified, inseparably associated with them, there would, for high potential currents, be little or no choice, but fortunately means have been devised whereby the existence of the cracks or crevices in the fibrous insulating envelops, when properly protected from water by a metallic casing, is immaterial, as they are sheared of the power of diverting the discharge into the paths opened by them.

These ends are accomplished by the simple expedient of causing the discharge to occur at such a place and in such a manner as not to pass through the insulating envelop.

This may be done in a great variety of ways; but the most simple one that has suggested itself to me is shown in figure 3, where A is the lead covering; I the insulation; C the conductor; and P a wire connected to A and extending out beyond I, its end, K, being adjusted in relation to C so as to leave an air space slightly less than the thickness of the insulating material I. Under these conditions when a discharge occurs it will invariably be at K and not through I.

While this simple arrangement illustrates the action and

answers as a means of protection, it is evident that some device more durable and capable of adjustment would be preferable. A design meeting these requirements is shown in figure 4.

In the figure, A is the lead covering; I, the insulation, and C, the conductor. Mounted on the lead A, and held in place by the band V, is the metallic arm P, carrying at its outer end the pointed rod R. Another pointed rod R′ is held by a projection on the ring B, which is mounted on the insulating brushing D. A fusible wire, F′, connects the ring B to the metallic sleeve or collar E. The distance between the points R and R′ can be adjusted, and the rods held in position by suitable screws.

It is evident that the operation would be similar to that of the device shown in figure 3. The electrical potential between the conductor C and the lead covering A, before attaining a height sufficient to discharge through the insulation I, will discharge across the air space between the rods R and R′, for these rods being in electrical connection with A and C, will attain their potentials; and the points of the rods will, according to known law, have an electrical density above that of A and C, or that requisite to produce a discharge across the intervening air. The fusible wire F, is inserted as protection against injury to dynamos and cables in case of a ground existing on the other side of the circuit.

There are several points, apparently trivial, but really of much importance, relating to the design and material of construction of a device for discharging a cable.

The distance, measured on the exposed surface, separating the points of support of the discharging arms or rods, should be as great as possible, as there would be a loss of energy, across this space, in case the distance was small and dampness existed. Another point to remember is, that the constant a, should have a known value, and, therefore, the most appropriate design for the discharger is one employing points to discharge from and an unvarying intervening medium, such as air.

In order to obtain some definite information on the question raised by Mr. Leggett at the Pittsburgh meeting, as to the effect on the insulation, of a short bend or indentation in the lead of a cable, I caused a very deep dent to be made in a cable, so deep in fact that it would at once have been condemned in practical work, and then connecting it into the working circuit, an attempt was made to cause a disruptive discharge to pass through the compressed insulation at the point of indentation, but the attempt was unsuccessful, the discharge preferring to occur at any other point.

Another experiment was made to determine the effect of bending the cable backwards and forwards several times in the same place. A length was selected in which the discharge always occurred at either one of the ends, and after the bending operation had been performed a number of times, I was able to produce the discharge through the bent portion in preference to the terminals.

These tests show the superior strength of the insulation in the more condensed or homogeneous forms, and the weakening effect of much bending.

In this connection it may be well to inquire more fully into the tendency of the discharge to occur at the terminals of the lead. It is a well-known fact that the greater number of the grounds or burn-outs that occur on arc light circuits are at the terminals of the lead, or at the joints, and it is precisely at these points that the charge, acting under well established and familiar laws, would be most dense, and owing to the presence of the edges or points for the electricity to flow from, the disruptive discharge will, under ordinary circumstances, take place between the edges or points, and the conductor within the insulation. Owing to the special facilities offered at these places, for the passage of the discharge, it is probable that in many cases, burn-outs occur under the influence of a charge that would be unable to produce a discharge through the continuous portions of the cable.

In order to reduce the probability of a discharge occuring at terminals and joints, I would suggest that the lead whenever cut be made bell shape, in order that all edges or points be turned away from the conductor.

It may be appropriate at this point to consider briefly, that vexed question,—"Which way does the spark pass?"

There is a relic of the past ages still existing, to a greater or less extent, among those who are unfamiliar with the present state of electrical science, and which I have no doubt many, if not all, of you have heard. The favorite way of expressing it is thus: "*The earth is the home of electricity and it is continually striving to get there by the quickest and shortest route.*"

By this theory the electricity as represented by the spark would always jump from the conductor to the lead and thence pass to the earth.

It is plain to see the great weight this would have in an argument against the near approach of the conductor to the earth, as is necessitated in the underground system of distribution.

The direction of the discharge is determined by the form or figure of the charged bodies and the characters or signs

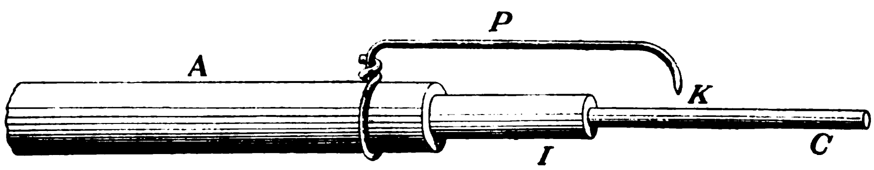

FIGURE 3

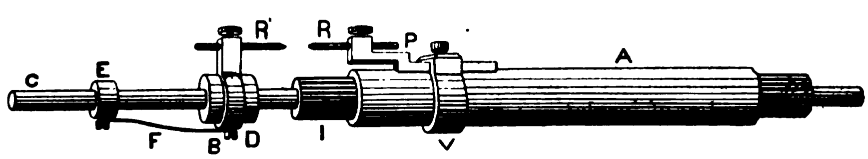

FIGURE 4

of the charges on them, the earth playing no part, other than that of a conducting medium.

On an underground system there is, the moment before a disruptive discharge occurs, an unstable equilibrium between two points of the system or rather of the conductors forming the system and the insulations or dialectrics separating them. Through the line joining the points there is a strain produced by the difference of potential of the points, the tendency being to a neutralization of the potential differences. Against this strain is opposed the resisting power of the dielectric intervening (and usually consisting of the insulations on the conductors and the earth which separates them). The disruptive discharge that follows, may be either from a conductor to the earth or the reverse, but in neither case is there the slightest quantity of electricity left in the earth as a result of the discharge. It is a transmission of energy from one point of the system to another of a different potential, and the amount of electrical energy lost in the passage is expended in overcoming the resistance, and appears as heat.

From the experiments and conclusions of Faraday, I have made the following deductions.

1. When the charged bodies are of the same size and form, the *spark discharge*, will, other things being equal, be *from* the positively charged body.

2. Other things being equal, less potential is required to produce a *brush discharge* than a *spark discharge*, and when it does occur it will be from the negatively charged surface.

3. In all cases where the charge of electricity is on, or closely associated with the discharging surfaces, a diminution of either surface will facilitate a discharge, and when any considerable difference exists in their areas, the discharge will always be *from* the smaller surface.

4. A spark from a small body to a large one will be from 8 to 10 times greater in length, when the small body is charged positively, than it would be with a negative charge.

In general, the direction of the discharge between the conductor and the lead, through the insulation, is subject to the form of the surfaces of the conducting bodies; a slight burr or point on either one being sufficient to determine the direction of the spark.

In a series of very interesting articles by Mr. G. L. Addenbrooke in the London *Electrical Review*, the subject of spark length disruptive discharges and the advantages of a perfectly continuous and unbroken dialectric are extensively treated. The influence of the capacity of the cable is, however, entirely neglected. Special stress is laid upon the advantages of a continuous envelop of insulation; and those using rubber covered conductors are particularly cautioned against handling or bending them when the temperature is lower than 45 degrees Fahr., as fissures or cracks are then liable to occur and permit of the passage of discharges.

This, I confess, was information to me and puts a certain limitation to the qualities I have given above to rubber. and which was written before this statement of Mr. Addenbrooke's came into my hands.

As the experiments referred to in this paper have extended over a considerable period (not less than six months), there have naturally been a considerable number of questions and points presented from outside sources. Others have been led into the field to experiment, and with the equally natural result of obtaining in some cases effects that they have construed to be at variance with those I have secured. I have one case in mind where the experimenters found it impossible to produce a disruptive discharge so long as the lead of the cable was insulated from the ground, but the grounding of it made the production of the discharge feasible, and they concluded that the theory of a disruptive discharge was not correct. This is a repetition, under different conditions, of the very old experiment of attempting to charge a Leyden jar with the jar insulated. The first condition to be arrived at in the charging of a jar is the grounding of one of the surfaces.

A disruptive discharge through the insulation of the cable, cannot occur without a charge being first formed, hence it is absolutely necessary that a ground be made to the lead.

The resistance of the ground connection to the lead is, to a very great extent, immaterial, as the charge is cumulative, and the energy expended in the discharge is only that held in the charge; hence though the ground resistance may be many megohms in value, and the charging process extend through a considerable time, there will eventually be a storage of energy on the surface of a value sufficient to rupture the insulation at the first change in the charging current.

The spark discharge is all but instantaneous in its action, and with the work restricted to this immeasurably short space of time it is necessary to have the energy on hand, as it were; there is no time to generate it, electrically, at the dynamo and convey it over long or even short distances.

The subject of disruptive discharges with various resistances and self-induction placed in the path of energy, is beautifully treated in a paper read by Dr. Oliver Lodge, before the Society of Arts, April 17.

One word more before closing this subject. It is safe to predict, that the disruptive discharge being provided for, little or nothing more would be heard of the much talked of pin holes in the lead, and the moisture absorbing terminals; the undergrounding of arc light cables would become a thing of certainty, and our municipal governments relieved of a great bug-a-boo.

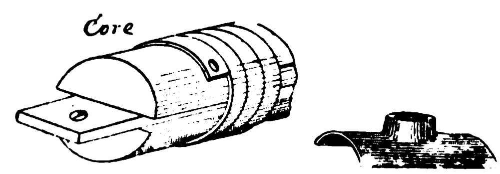
Mr. Acheson was followed by Mr. A. C. Chenoweth, who read the following paper:—

DESCRIPTION OF AN UNDERGROUND CONDUIT.

BY ALEX. CRAWFORD CHENOWETH, C. E.

The changing of electric light conductors to an underground system having engaged the attention of this meeting, I will place before you a method of constructing ducts that can be so arranged as to meet many of the objections heretofore presented.

The object of this paper is not for the purpose of discussing the merits or demerits of systems that have already



FIGS. 1 AND 2.

been presented, but to invite your criticism of the practical points of the method I am about to describe.

Let us assume that the subject of insulation has been settled, and that an arrangement of conductors in a structure permanently located, is so contrived that demands from time to time for an increase in numbers can be met at a small cost. This being done in order to meet the financial question. The material from which to build these structures must withstand the forces of nature that are brought into action in their new relations. Concrete, a mixture of Portland cement and sand in suitable proportions, well incorporated, answers all the requirements.

The form of the structure requires a system consisting of ducts 4″ in diameter, with large man-holes located at convenient points for purposes well established in previous discussions, with other entrances to the ducts, through openings located at intervals, to be used when required as connecting points to houses and stores. All parts should be

constructed with smooth interior, free from joints, faults, depressions, and water tight.

The structure is formed by means of a core which consists of a wooden cylindrical rod, made in lengths of 14 feet or 20 feet, which is cut in two, forming two half cylinders. The space removed by sawing through the rods, when the halves are placed together, is occupied by an iron rod, having a thickness equal to the portion removed by saw, restoring the cylindrical shape; this forms the mandrel or core shown (figures 1 and 2).

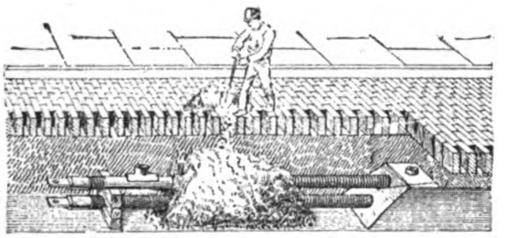


FIG. 3.—Chenoweth Conduit.

Now, a ribbon of galvanized iron, one inch wide, and of a thickness equal to 27 gauge, is wound spirally around the mandrel of wood, from end to end, securing the ends with a fastener to the wood, to prevent unwinding. The outside of core is now painted with a mixture of clay, powdered soap stone and water.

The core thus described is ready for use. A ditch is prepared, the core is placed in it, resting on cross-pieces of wood; if more than one duct is to be constructed, other cores are ranged side by side. The concrete in a plastic state is now tamped well around, bringing the top to an even level. The iron rod is now removed, as well as the pieces of wood on which the ends of core were resting, also the fastenings of the ribbon ends. The wooden half cylinders are now drawn out, leaving the spiral casing, which remains for several days.

A new core is inserted in the end of the spiral, the ribbon of old core is fastened to ribbon of new core by a swivel, and you proceed in same manner as before, thus constructing several hundred feet with the casing remaining in. When the cement hardens the casing can be drawn out, being a spiral; this being done at any man-hole or unfinished portion of the work. As the spiral ribbon is removed, the surface coating of clay and soapstone adheres to the interior of the duct, producing a smooth surface, and acting as a lubricant to reduce friction, when conductors are drawn in, preserving the insulation. This construction insures a monolithic structure, smooth interior,

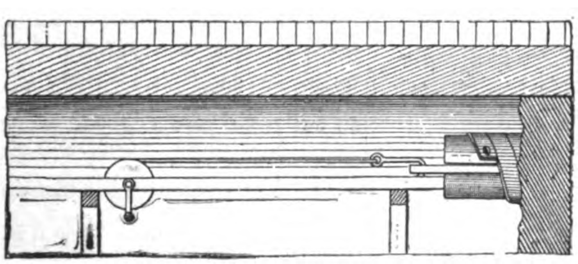

FIG. 4.

straight, free from joints, depressions, and water tight by reason of its construction.

At the same time, in case you should require another duct, the wall on one side is always ready, by merely placing a core on top or on either side and proceeding in same manner; this reduces the cost of a new duct. The most convenient arrangement for distribution purposes suggests a line of ducts on each side of street, with man-holes at intersecting streets, and openings at every house lot subdivision.

I have adopted an opening in the form of a cast-iron nozzle, with a hole into which a pipe can be screwed, by removing a screw plug; the same being set in the cement when constructing the duct, leaving the nozzle projecting only. This can be modified to suit any size or shape, or the nozzle can be replaced with a box having a lid. This form of construction will permit the conduits to be placed near the surface; the elasticity of concrete enables it to withstand the blows caused by heavy traffic. It is an easy matter to project a conduit of this form from a man-hole to any desired point, and afterwards to construct others alongside at small cost.

The cost of constructing ducts by this method is narrowed down to the winding of the ribbon on the mandrel, the labor of removing the mandrels in the trench, and removing the ribbon from duct, and re-winding the ribbon on bobbins.

As each part of the core is preserved and used an indefinite number of times the cost of the core is charged to cost of plant; it costs ten cents per foot. The winding of the ribbon is done on the spot as fast as wanted, and costs two mills per foot, the cost of drawing out the ribbon and re-winding on bobbins, using an ingenious device that removes all twists, costing about one mill per foot. The labor for removing the wooden mandrel in the trench is about one cent per foot. A duct 4″ in diameter, made of con-

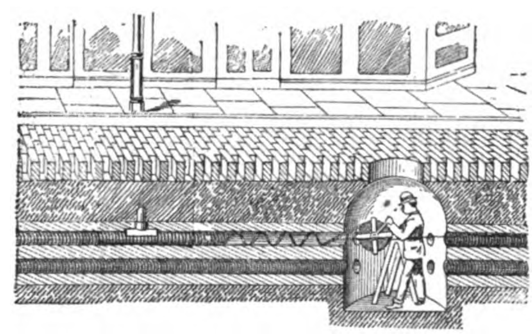

FIG. 5.—Chenoweth Conduit.

crete, one of cement, two of sand, can be made for four cents per foot, including entire cost, exclusive of excavation, man-holes and openings. In case a repair should be found necessary a block can be made with a duct through it, and inserted between the two ends thus to be joined, leaving a space of one inch at each end. Insert a spiral sleeve inside of duct, made of iron, a wire fastened to the end of ribbon forming the sleeve (also connected to sleeve at other end of block by wire), then extend to nearest opening, pack the cement between the ends firmly, the sleeve preventing the cement from entering conduit. When the cement forming the joint becomes hard, the sleeves can be removed by hauling on the wire at opening.

The president then announced that the afternoon session would be devoted to the discussion of the general topic presented in the three papers just read.

The chair then announced the appointment of the following committee on the president's address: Messrs. Arthur Steuart, of Baltimore; A. F. Mason, of Boston; J. Frank Morrison, of Baltimore: E. R. Weeks, of Kansas City, and H. D. Stanley, of Bridgeport, Conn.

The President—I understand that the Brush Electric Light Co. have commenced putting in their cables at the corner of 15th street and Broadway. Before we adjourn I would like to ask Dr. Wheeler if he knows whether they will be at work for the next two hours, and if so we will arrange to allow those of us who wish to see them at work an opportunity to go there.

Dr. Wheeler—The men will be at work there by the time the members of this association can get there. I think they go to dinner about half-past twelve.

Mr. Lynch—Before we adjourn I would offer the following resolution:—

"*Resolved*, That a committee of five be appointed by the chair to examine into and report upon the systems of underground conduits for underground conductors and conduits now in operation,

and the number of wires actually in use in those conduits, and report at the next convention of this association."

On motion the resolution was adopted.

The convention adjourned till half-past two o'clock P. M.

THURSDAY AFTERNOON SESSION, AUGUST 30.

The president called the meeting to order at 2.30 P. M.

The President—In the absence of the secretary I will read the following communication which has been handed in :—

"If desired by the members, arrangements will be made for those attending the Broadway Theatre to see the electric light plant there. As this plant is a very complete one, and was installed under the inspection of the navy officers, it has many interesting points." C. J. FIELD."

The president also read an invitation from the Shultz Belting Co. to examine, at an establishment in this city, a belt said to be the largest in this country.

The President—We are now ready for the discussion of the three papers which were read this morning. I see that Dr. Wheeler is present. Some of the gentlemen, after the reading of his paper, were asking some questions, which the chair stopped, as they were leading to a general discussion, but Dr. Wheeler will be ready now to answer any questions which may be asked him.

DISCUSSION ON SUBWAYS AND UNDERGROUND WIRES.

Mr. Lynch—I would like to ask Dr. Wheeler what number of wires it is proposed to put into these two and a half inch ducts.

Dr. Wheeler—I do not know exactly how many they propose to put in. I suppose it will depend on how many the ducts will hold. But there is now being drawn into them a cable containing eight arc light conductors, each one of which is equal to a number four wire. They are made a trifle larger than the ordinary overhead conductors. That makes a cable which, including the lead covering, is about two inches in diameter. I should think it hardly advisable to draw a larger cable than that through these tubes; but hereafter probably there will be no cables drawn in containing more than one arc light conductor. They will be drawn in singly. The objection to the cable containing a number of conductors is, that it limits the use of the cable to carrying a number of wires all forming the positive or negative side of the circuit, while if you make them up into single conductor cables you can arrange them to suit the convenience of business, and you have an increased amount of insulation between opposite wires.

Mr. Lynch—How far is this cable to run?

Dr. Wheeler—From 14th street to 34th street on Broadway.

Mr. Lynch—What is it to be used for—trunk lines?

Dr. Wheeler—I do not know exactly; I think not, from the fact that it is proposed to cut it in two at each man-hole.

Mr. Lynch—Have any supplementary conduits been laid?

Dr. Wheeler—None have been laid that I know of for the use of arc light companies. The method has been adopted and the materials are being gotten ready to lay a system from 14th street to 34th street on Broadway.

Mr. Lynch—Is that the Johnstone system you spoke about?

Dr. Wheeler—Yes, sir.

Mr. Lynch—What is it proposed to charge as rental per mile?

Dr. Wheeler—I do not know. For that I will have to refer to the representatives of the conduit company.

The President—Dr. Wheeler, will you allow me to ask you a question. If the city authorities have charge of the streets and are responsible for that conduit going in there, how then are you going to hold the owners of the lateral wires responsible for anything at all? How do you propose to do that? Has the commission any plan on that point?

Dr. Wheeler—It occurs to me that that is a question of law, and I am here as an electrician—not that I have any objection to answering the question, but I do not know the answer.

The President—I see. But is the representative of the law department here?

Dr. Wheeler.—I would like to refer that question to Commissioner Gibbens, if he is present. I do not see him.

The President—We are seeking for information, and we are as desirous of a solution of the problem as the municipal authorities are. When we get to a point where there is a dead line drawn and the municipal authorities cannot give us any information, we have got to stop right there. If there is a point where we can give you information, we are desirous of aiding you.

Dr. Wheeler—I am very desirous of having all possible information given to the association in order to make the conclusion reached as valuable as possible, but in the absence of Mr. Gibbens, perhaps Mr. Leslie, who is present, and is the manager of the subway company, might answer that question.

The President—You understand the proposition,—that as the municipal authorities by law take charge of the mains and regulate the sizes of the conductors, etc., and become responsible for those mains in the street, then, as I understood the proposition this morning, the companies who would feed off from those conduits would be responsible for the lateral mains. Is that correct? Now then what we want to know, if we can get the information, is this—where the responsibility of one commences and where the responsibility of the other ends.

Mr. Leslie—As I stated this morning, I think the responsibility of the subway company ends in providing a suitable subway for the accommodation of such conductors as any electric light company or any other company may see fit to draw therein. They are responsible for the kind of insulation and for the operation of their own plant; they own it; we do not. We simply own subways which we lease to them.

The President—Then, in other words, as I understand it, the city authorities have practically made a monopoly of the underground business of the streets, and given it to a certain company without any specifications as to the character of the conditions that the lighting companies must undertake to fulfill in making connections with the main conduit system. Is that it?

Mr. Leslie—In the first place, as I understand it, when the commission was created, each and every party interested was invited to submit its plans for such a system as in their judgment might be most suitable to their business purposes. Having failed to do so, the subway company has since observed the same practice, and each and every company in the City of New York doing business here has been invited to state what in their judgment would be most suitable for their purposes. I think the attitude of the subway company in that respect has been most consistent. If a man wants anything and asks for it and gets it, I do not see that he can ask for any more.

The President—Then, as a matter of fact, the subway commission of the city does not say to the electric lighting companies that they must observe proper sizes of wire, and everything of that kind. They leave that to the discretion of the company.

Mr. Leslie—Entirely so.

The President—They simply ask them to make a recommendation?

Mr. Leslie—They ask them to go underground.

The President—And if it does not suit the conduit company, what then?

Mr. Leslie.—We have had no such emergency arise as yet.

The President—Is there a basis then established by the subway commission or the company under the subway commission—is there a set of fixed charges established?

Mr. Leslie—There is, and it has been furnished to the companies.

The President—Have you received answers from the companies in regard to that question?

Mr. Leslie—We have met with no opposition in that respect from any company in the city except one.

The President—They are all perfectly satisfied with the rate of charges?

Mr. Leslie—They appear to be so. They think it to be just and equitable.

The President—In the furnishing of this subway, do you give any guarantees to these companies as to the permanency and the reliability of the system that you put in?

Mr. Leslie—We agree to keep the subways in good order.

The President—Practically, you agree to maintain them free from trouble.

Mr. Leslie—Yes, sir. But if anything that could not be anticipated should arise to interfere with their business, they would not be in position to be reimbursed for any loss they might have incurred during that time.

The President—Then practically, you do give them a guarantee?

Mr. Leslie—We guarantee to give proper subway facilities or we do not charge any rent; that is the best we can do. If we should happen to have some extraordinary accident which no one could anticipate or provide against, in that case we should, of course, abate any rental until such time as we could put the subways in good condition.

The President—Then there are no conditions by which a company which is held responsible for lighting to the public could obtain redress for lights being out for a period which would be practically inconvenient and would cause considerable delay in restoring service?

Mr. Leslie—I do not know of any guarantee beyond that which I have stated.

The President—Yes, that is what I understand. Then it is the companies which practically loose the amount of revenue that would be lost, instead of the subway company that puts in these conduits?

Mr. Leslie—Well, I presume so. They do so now with the overhead system.

Mr. Perry—This is a subject that is entirely new to us and we may have to meet it in our own various systems, and I would like to ask what are the rates of tariff which are established here, and if the City of New York gives into the hands of a corporation the right to lay these subways without any limitations as to what tariff they should charge, and then say to the companies, you must go in, no matter what the rates are? I would ask if there is any limitation of the tariff and what the rates of the tariff as established are?

Mr. Leslie—I will say with regard to that matter that the companies are amply protected. The law on that subject reads

that such a rental shall be charged as is fair and equitable. Any company imagining itself imposed upon in the matter of rental, can have recourse to the board of electrical control, which has the right of revision at all times. I regret that I have not with me a copy of the law on the subject, which I imagine from the inquiries which have been made would have gone very far to enlighten the gentlemen present. There is no opportunity for unjust action.

Our schedule of rentals is $1,000 per mile per annum for a three inch duct; $800 per mile per annum for a two and a half inch duct; $750 per mile per annum for a two inch duct; $550 per mile per annum for an inch and a half duct. I will say that with regard to the two inch duct I am not clear whether it is $750 or $650, not having the figures with me.

The President—You will understand Mr. Leslie, that these questions that we ask are not asked in an inquisitive way to ascertain the private business of the subway company; but this City of New York has been looked to from all over the United States as the point where this question is to be solved. We have been invited by the mayor to go into the merits of this matter if we can, but there is no use in going into the electric part of it unless we can get at the financial part of it too.

Mr. Leslie—I appreciate that, Mr. President, and I want to say that while the scope of our operations is local yet we recognize the fact that the underground problem is universal, after all, in its application, and that in most of the prominent cities of the United States you are all face to face with the same question, and that the developments of underground facilities in other cities is going to be directly and indirectly a great help to us here in New York. I desire to say further, that if any individual member of the convention desires any more definite information upon the underground system, which we may possess, if he will apply at our office, 18 Cortlandt street, in this city, we will very gladly give him all the information that we have.

Mr. DeCamp—As I understand the matter, when this subject was put into the hands of the subway commission, they invited the different electrical interests to state to them what was necessary for a successful solution of the problem of laying underground wires. These different electrical interests, particularly the electric light interests made no response to that invitation, for the reason, which is manifest to every man engaged in the electric light business, that they had no suggestions to make because they knew no practicable method. Then the subway commission took upon themselves the responsibility of deciding upon some conduit which in their judgment would answer the purpose. Those conduits have been put down not upon any merit that has been demonstrated; but as mere mechanical constructions they seemed the proper thing. After that is done then comes the pressure to have the electric light companies put their wires in them. That pressure is brought to bear very forcibly because it is backed up by legislation. The commission have assumed the responsibility of deciding for the electrical companies in putting down a certain conduit; but they throw off their responsibility and say, "Gentlemen, occupy those conduits at a rental of so much a mile." The only risk that they take in the matter is in keeping the conduits in repair. They throw the burden on the electric light companies, and as the chairman very pertinently puts it, who is responsible to the electric light companies for the loss of service to the public by reason of the failure of the conduits during the time it is necessary to repair them? Not only that but the failure on the part of a cable or conductor that they put in, though not upon their own judgment but upon the judgment of the parties who put the conduit down. There is a consequential consideration or risk there which, in my judgment, it is unfair to impose upon anybody. That is about the way, as I understand, that the thing stands to-day. There is only one certain element in that for the companies using the conduits and that is—to pay rent. But leaving that right there, this is what has always occurred to me from the time this question was agitated. It has been taken hold of at the wrong end. I never saw a more preposterous method of accomplishing a thing. Mr. Lynch asked a question this morning about a certain conduit in Philadelphia. That that conduit in my judgment is a good one goes for naught. I do not care how good it is, and I do not care how cheaply it should be built, but I have got absolutely nothing to put in it that will answer the purposes of our business—absolutely nothing; and here you go to work and you devise a convenient method of transacting a business which you admittedly do not know how to carry on. There is not a man to-day who is willing to take the record of the aerial lines as a basis for operating, and that is of no mean importance, because the investment of a vast amount of capital and its earnings are based upon the amount of money in those constructions, and you never get any more out of it. You have reached the maximum reward of the investment of your capital. The public has given it to you and given it to you willingly. They say to you: Your business now, young as it is, is old enough for you to have learned something, and you have brought that business to a point at which it ceased to be a luxury to those who want to use it. The City of New York paid 70 cents per night for arc lights without a murmur in the first few years of the business. They declined this year to pay 50 cents. They declined to pay 45 cents, and there are plenty of cities in the country that are paying less than that. They say it is too expensive. Therefore, you have got to weigh with great deliberation anything in connection with your business which compels you to increase your prices or to maintain those you have already established. The commission put down these ducts; they have occupied the streets, and they have left the companies who shall choose to use them to accomplish that great end of getting something to put in them. Now I asked the question this morning of Dr. Wheeler, who represents the subway commission, what these conduits cost. He does not know. The matter is referred to Mr. Leslie, he does not know; and from all I can learn nobody has ever taken the trouble to consider the cost of this thing. Now I want to submit that as a method of doing business. When I go to my company and say "There is a report; it involves the introduction of new machinery, the addition of a few boilers, the addition of some electrical apparatus that will enable us to do so much business; it will increase our business 10, 15, 20 per cent." do they say "Go on and do it?" It is just what they want done; but before they do that they ask, "What is that going to cost?" The commission have gone before the authorities of the city who are pressed on all sides to do a very desirable thing. Their plans look very feasible as a piece of engineering. His Honor, the mayor of this city, takes the most sensible view that ever I knew a public officer to take. (Applause.) He is a man who has the courage of his convictions, and it is a great disadvantage to the electric interests to-day that there are not more of our municipal officers who seem to have the same courage. The mayor of this city stands in a position which no electric light company dare antagonize. If this subway commission brings forward a practicable system and he carries out his intentions of enforcing it, I do not believe there is an electric light interest in the City of New York that dare for a moment antagonize him. Certainly there is not in Philadelphia an electric light interest that would dare to antagonize a municipal officer taking such a position. Now that is a sensible view to take of it. It is a question of dollars and cents, as has been many times asserted on this floor. That assertion amounts to naught until the amount of those dollars and cents is stated. This thing carried on to the extent it is proposed to be carried on in New York, if I have an appreciation of the subject at all, would ruin every electric light company in the United States, and every dollar of capital invested in it would be wiped out. No industry that ever started has sustained itself as this interest has sustained itself since its inception. Gas companies never met with the same obstruction nor did any other public industry. Just as soon as the electric light companies impressed themselves upon the minds of the public that they were a public necessity, every facility was offered and no obstacle was set up any longer. We are met here with this subway project, commencing as I say, at the wrong end to do an important thing before we know how to accomplish it. As to the guarantees. I can readily see how the commission cannot assume that responsibility. It is utterly impossible for them to do it. It has been said here that certain manufacturers will put a cable in with a guarantee. Now I understand that that has been done in this city. I am curious to see in what form that guarantee is. If it simply means "we will put that cable in there and run it for a year or two, or three years, and in case it fails we will take it out and put in a new one;" in my judgment it does not mean anything. Who would think of renewing the gas pipes in the City of Philadelphia? What electric companies at the present comparatively low cost of aerial lines would think of renewing their aerial lines once in ten years absolutely? It would make the business prohibitory. The substitution of a new cable is no small job; the consequence is that while it is being substituted the city is without light. Now that is a thing that the companies themselves should be compensated for. It is not likely they would be. In the City of Philadelphia and I think in the City of New York there was not a gas light removed on the line of electric lights for one year after they were started. Why? Because confidence was not established in it. People thought it might go out on them. But gradually confidence got established, and now wherever it is possible gas light is turned out, and the very rare failure on the part of the electric light has justified that confidence. I am sometimes amused at the easy, self satisfied way in which people say, "What does it do? Pull this right out, and put another one right straight in." On the same cable, perhaps within two available points for making the change, are half a dozen different connections all of which have got to be unsoldered and the cable taken out, another put in and the cable soldered up again; that means a delay and the loss of a certain order, public or private, and I assure you—and any man that is in the business needs no assurance—that such a thing as that would not be tolerated. Customers would say "The thing is too uncertain; we do not want it. If these things are to occur even occasionally it fails to answer our purpose." When it comes to that, gentlemen, your electric light as a common and public illuminant is a failure.

Now I am just as anxious as any man to have this question of underground wires solved, and I believe every company in the

country is willing to do their share of it and are making the best efforts to do it; but you can readily conceive when you look at the City of New York and note the progress that is being made in it,—I mean the substantial progress—that it is not very encouraging to us to go to our companies and ask them to spend money to repeat the same operations that have been made in New York. That is not business. We should benefit and profit by other people's experience. It is one means of education that we have without paying for. In the City of Philadelphia we have made our effort. It is not expected that the people of Baltimore in the same line of business will go and do just the same thing that we are doing, but every effort has been made in Philadelphia from a straight square out and out business standpoint based on an investment of capital, to meet the public demand. I declare here without fear of contradiction it has been an absolute failure. The parties that have been endeavoring to make a success of that have had every interest in the world to bring success about, and yet it is a failure and there is no denying it.

Professor Van der Weyde—Our mayor, notwithstanding he said that he did not understand much of the electrical business, gave us very good advice to devote our efforts to solving that great problem. I have been attempting to solve it for some years. When I first saw that the wires would have to go I made individual experiments and have patented cable. I have also obtained patents for anti-induction cables, but in the place of getting up a company to try to introduce it I put it to a severe test myself and I found, after burying the cable that it did not stand the honest test; and therefore I have not come before the public or before any company with my patent. The position of the matter is this: There are two things to be accomplished by us. In the first place we have to devise a subway which is available in a large city so that the cables can be gathered. It is a significant fact that in the City of Paris, where they have the most magnificent opportunities for putting the cables underground, in their sewers, only the telegraph and telephone cables go through the sewers, and all the electric light cables, as stated this morning, go over the roofs of the houses. It has been found not to be practicable in Paris. It is a problem to be solved. We must find first the proper cable to put underground, and then the proper subway. We have seen this morning a cable passed through the tubes. That is very good and very useful, when we have to go a considerable distance, like passing over the Brooklyn bridge or the approach to the bridge, for instance, through Frankfort street; it is splendid in such a case; or uptown through Broadway. But if we want a system where every wire is accessible, it is insufficient. Such a system has yet to be devised. In the second place, proper cables have to be devised which will not give out, and the best we can do is—what I have done, Mr. President—to recommend this body to make their individual effort to improve the things we have and to get subways which will answer the purpose, and to get the proper cables. By the way, in Brooklyn, for instance, the subways have been laid down under my sight as it were. I saw it from time to time, living there. Three years ago they commenced, and what has been the result? They are now pulling out the cables they put in three years ago. Their cables have been found insufficient. If things had been commenced after we had the proper information, then such losses would not have happened.

Dr. Moses—Mr. President, I have just received a despatch which exemplifies better, I think, than almost anything else, one of the bursts of eloquence of the mayor which he gave us yesterday. He said he would like to see electricity really the servant of man for the good of all. This despatch exemplifies how electricity may come to our aid and bring those who are in sympathy with us, though three thousand miles away, right within sound of our voices, and close enough to touch the chords of our hearts.

Dr. Moses, Hotel Brunswick, New York:

"Reckenzaun and friends send greeting to the convention." (Applause.)

Gentlemen, while I am upon the floor I would like to correct an impression which, coming from one of so sound judgment and so painstaking as Professor Van der Weyde, may have impressed you deeply. He says that the subways in Paris have not been used for reasons which would lead you to infer that it is due to the fact of the incompleteness of our knowledge in the distributing of electricity through conduits. That is not exactly the case. The facts of the case are these: The City of Paris and the gas company are in a close partnership. They do not want to have any electric lights there because one of their chief sources of revenue is gas. We often hear a great deal said about Paris being the representative city for everything that is in advance in science, art and luxury, and we are inclined to say this thing should be developed there. To-day there are not half a dozen arc lights in Paris outside the Place du Carroussel. The reason is, the city found every impediment in the world in the way of electric lighting. It is bound to come though, and those who are deeply interested in the subject in Paris are bringing it about in the following way: A company has been started in Paris which is seeking rights from the municipality to introduce a system of power throughout the City of Paris. They entirely ignore the uses of it—electric light, transmission of power for motive purposes, for electrolysis, for all the other uses to which we apply it here, are entirely ignored by them, and they propose simply to sell power. Now when the time comes, of course for the distribution, it is not impossible that the magnificent system of sewers which underlies tariffs may be utilized by any company that may have the right to do it. That right will only be conferred on those who can give guarantees. Those who are introducing the electric current for power purposes in Paris, are a syndicate, or rather a company controlled by the house of Rothschild, so that there is every guarantee in the world that when that thing is undertaken it will be done thoroughly and no doubt successfully.

I am now tempted to refer to something that has been upon my mind for quite a time, and at the end of this discussion I feel inclined to bring it before you—not in the prophetic spirit to which you have been inclined to attribute most of my address, but because it seems to be the solution of the distribution of power in the City of New York, in which, as Dr. Wheeler has said, more business is done in a small place than in any other spot on the face of the earth. The subway commission have undertaken a great task, and as far as they have gone they have done it as well as the present state of the art will permit. That is a meed of praise I think we will all accord them. But I am tempted to think of an anecdote which Mr. Barnum relates in connection with that. I do not intend by quoting it to cast a reflection on the subway commission. Mr. Barnum says that in his experience one of his friends got married and received a present of a very magnificent velvet sofa, very comfortable to lie on but not at all in keeping with the length of the young man's purse. He did not have it long before it was found necessary to change all the furniture in the parlor. That necessitated a change of all the furniture in the dining room, and that was followed by a change of all the furniture in the bed room and the whole house, and if it had not been for an unexpected run of luck that young man would have been ruined by his sofa. Now several people have acted in such a way as to furnish a magnificent conduit. It will be furnished, and the fruits of it will be enjoyed as this young man did through his unparalleled prosperity, and electrical power will be distributed through the ducts now in the city under the control of the subway commission, and it will be a success. But I will suggest that it may be done most advantageously in this way: If we look at the supply of light, water and steam that we have in New York, we find that everything is distributed from a central point at an equal pressure. If we were to use the 42d street reservoir to-day people would say it is ridiculous, because we have a higher source of pressure. The reservoirs in the park are ornamental lakes sometimes, but even they might be done away with. We might go to High Bridge and put up stand pipes as they have done there and get a uniform pressure. The only thing necessary for the distribution of power to make it available to every consumer is a constant source of pressure and an unlimited amount of power. How are we going to accomplish that? If we look at these subway ducts we will find they are not as in the human body—every artery, every vein, every nerve connected with some simple point of uniform distribution and pressure; but we find through one orifice is to go a power say of 100 volts, through another one of a thousand volts; through another one of 2,000; through another one of 10,000, all acting by varying inductions upon each other, interfering with each other, and really giving you no means by which if an error or a waste is introduced it can be interrupted without in some way affecting the other potentials. That introduces an element of variation which is to be avoided. How then can that be done? In the present state of the art it is as easy as furnishing a mild current of water for washing the hand, or a powerful one to the bath tub, or one still more powerful for taking the shingles or slates off a roof by means of the steam fire engines, all from the same source of power. But we must be able to distribute from a constant source of electrical power potentials of any height. How is that to be done? It may be done in such a way that the original source can be entirely safe-guarded. My friend here speaks of the conduit being a success, but he has not anything to put into it. Why? Because insulation has not been carried to that point of protection where you can say that you have a source of insulation of unlimited light. It is wearing out all the time. Now then we must have a conductor of such character that we can say when it is put down it is never going to be touched; it is a constant source of power, as regular as the sun for its heat, and there it is to be disturbed and changed into any condition that we desire. How is that to be done? Gentlemen, it is done partially for electric lights to-day. You will find conductors, particularly in Pittsburgh—where I saw them very extensively distributed—conductors of very small dimensions going through the streets carrying 1,000 or 2,000 volts and then being distributed in potentials of 50 volts. I would like the ducts of the subway commission built with a series of conductors all electrically connected and having a potential great enough to enable all the force that is necessary to be distributed through this vast metropolis and be permanently there as a source of supply without in any way seriously incommoding our streets. All the current necessary to run all the machinery of the electric light, telegraph, telephone, burglar alarms, and so on, could be carried

through a conductor one foot in diameter that could be laid through the streets of New York. It could be so carefully insulated that not 100 millionth of it would be wasted. It could be made available at any spot in the smallest quantity and in the largest. Let any accident happen to any piece of machinery, and it should not be able to interfere with the enormous power behind it. There must be nothing to interfere with the great current of force that should circulate through the city. That to my mind is the *beau ideal* of the distribution of power. Now, then, how to do it. We are stumbling upon a thousand difficulties, but I think they can be arranged. You have interests of various kinds—electric lights, power, and so on,—all of them running antagonistically: How can they be persuaded that such a system as this is best? Simply by showing to them that they may unite their forces for the furnishing of this power. You cannot put up in any one place a station that would be sufficient to supply the whole of it. It should be like a series of ganglia pumping into this great main artery the power that is necessary. Let them all pool their issues and pump into one station and from that point let it be distributed, if you please, by the underground commission or by any one who will take charge of it. Let the source of power distribution be the essential feature. It is immaterial to me whether the power is used for lighting or another purpose; power is at the bottom of it, and power should be furnished in the most equitable and most useful way.

Now that is not by any means Utopian. It would enable you in the smallest area to safeguard your current in such a way that it would not be interfered with by any other interest. It should be distributed through all the streets of the city just as water is. It can be done, and in a very much easier way than people imagine. Gentlemen, to my mind that seems to be a solution of this whole difficulty. Of course for minor distributions that can be very easily accommodated, because between any two blocks you have but a small sub-distribution to make. That can be easily accomplished. Transformers of current can be put everywhere and anywhere and attached to that main source of supply and measured in the simplest way possible without any danger. We would have arc lights in our houses then. Do not think, gentlemen, that I am trying to derogate from the importance of the arc light interests. People instead of having arc lights in the streets would be satisfied to bring them into their rooms if they knew there was no danger. Transform your current from one of 2,000 volts into 50 volt currents, and you will find your interest will be ten-fold magnified inside of a year. Gentlemen, I have nothing further to say, but give you that to digest.

Mr DeCamp—The remark of Dr. Moses lead me to think that I might have been misunderstood. I believe with him that almost anything is possible. I do not by any means wish to convey the impression that we will not reach this very desirable end. While I do not propose to be a skeptic in this matter, yet on the other hand I do not propose to be an enthusiast. I cannot discuss that question from the point of view at which Dr. Moses and many other gentlemen in this association are entirely competent to discuss it. That is not my line of business. I am simply a man in the business who has to look out for the financial interest of his principals. I have got to see that their investment is properly made and reasonably remunerative. The chairman asked me to make some figures, and I submit them, knowing that figures not supported by data are dangerous things to deal in; but I want to submit them and take the risk, depending upon the good judgment of the members of this association who have experience in that line to believe that I am conservative in regard to these figures.

Eight hundred dollars a mile rental for the use of conduits—not the furnishing of wires and circuits, but simply as a tenant, $800 a mile for a conduit or duct which cost $500 a mile. Now the gentlemen who framed that schedule must have had in their mind's eye a wonderful depreciation to ask more than 100 per cent. on their investment the first year; but admitting that it may be justified by something of which they are the most competent to judge, my experience in the conduct of an electric light station is that it is a pretty difficult thing to distribute more than 50 lights in a circuit of two miles. We do not do it in Philadelphia. But I am going to say two miles for 50 lights, a 1,000 light station under those conditions—I wish somebody would go over this after me.

Mr. T. Carpenter Smith—I would like to ask if that $800 rental refers to the ducts or to a single wire?

Mr. Perry—It was stated that it was a single duct—a $1,000 a mile for a single three inch duct.

Mr. Smith—Suppose Mr. De Camp keeps to the conditions that apply to the cable now put in.

Mr. De Camp—That is a thing in which you might do yourself injustice. I will come to that point before I get through. Now to answer the question on the basis suggested, it is true that it does not follow that our mileage should be the number of lamps divided by 25, because certainly as a matter of economy in rental we would use the same duct where we could until we got it full. Now to what extent you could do that is a matter that is only guess work. But I cut it in two—divide it by two if you choose and pay $80,000 rental a year for a 1,000 light station and figure out where your dividends would come from. Divide it by four—

Mr. Apgar—May I offer a suggestion here? Could Mr. De Camp reach the conclusion he seeks—I see what he is after—by ascertaining what it would cost the whole plant with which he is connected to put that whole plant in the ducts furnished from $550 per mile per year to $1,000 per mile per year. He knows how many miles he has in circuit and he can determine what would be the annual expense for rental by placing all of these wires in ducts. You could reach that quite readily could you not?

Mr. DeCamp—No, I could not do that quite readily. Anybody who has had experience in distributing light for a central station knows that his first calculation of the first cost is apt to be deceptive. Now we run wires from our central station, not with the view to supply the particular lights we may run them for at first, but we run over a district, if we have the privilege and opportunity of doing it, by which we think we can utilize that wire to the best advantage. In other words, we might go to get 10 lights, in a direct line of a mile, if the 10 lights were our only object. Very probably we would choose to put out five miles of wire, over a territory from which we would draw other business. Therefore, for me to make a statement on the basis of the wires we have got would be more uncertain than the figures I have already stated.

Mr. Smith—Mr. DeCamp has made one statement which I think is entirely right—that this question of underground wires has been taken at the wrong end, but I do not agree with him as to the way in which it has been begun at the wrong end. I maintain it has been taken at the wrong end in some cases, because the men who have been getting up these various reports on underground wires are the men most directly interested in underground wires not being a success. We are told over and over again of the failure of underground systems, and it reminds me of the old story of the man who had stolen the cow, and one person was produced who saw him do it, and he replied that he could bring forward 20 men who had not seen him do it. Now I maintain that in a case of this kind one good instance of successful work is worth 40 instances of bad work. When Mr. De Camp states that there is no successful underground work in Philadelphia I think he must have forgotten what I told him in Pittsburgh, that I had 15 miles of wire running underground in Philadelphia without any trouble. We supply eight newspaper offices, and I think any one who has ever supplied a newspaper office will agree with me that they are the hardest to please of all our customers. Those eight newspaper offices have cut off their gas entirely and are entirely depending on our supply. We are using 1,000 volts of alternating current. We have never taken out a single cable but one. That was a small piece of double conductor No. 10 wire which we pulled out owing to a short circuit having taken place in the cable itself, and we had the lights running again in six hours.

A great part of Mr. DeCamp's speech was taken up with what seemed to me to be simply an attack on the subway commission in this city. Now with all due deference to the subway commission here, I do not see that their action in this city has very much to do with the convention. It is very hard on electric light companies, I grant you, to have to pay any such rental as $500 per mile per year, but Mr. DeCamp has been very anxious to know what it is going to cost to put the circuits underground. I have laid altogether somewhere between five and six miles of underground work in a 16-duct box, fitted up complete, with three man-holes to every square, counting everything from the digging of the trenches to the repaving and giving a bond to the city, will cost him about $7,000 a mile. That does not include the cables to be drawn in. He has made the statement that matters of this kind are put in the hands of men to legislate upon who know nothing upon the subject. Very true. Now I happen to know of a commission that is appointed to examine into the question of underground wires, who came to a certain city where there were a number of arc lights which were reported to be running satisfactorily by the man who was operating them, where there was an incandescent station operating from 2,200 to 2,500 lights on underground wires, running for two years without any trouble, and a gentleman who had a large arc light station in that town got hold of that commission, took them around in carriages to the park and to the theatres, and that commission went away without seeing a foot of underground wire, and I have no doubt made a report on it. That is a good way to help people who are ignorant of the subject to find out about it. But it is hardly the way a business man would go to work. I am afraid I may be looked upon as a crank on the subject of underground wire. I have put money into a company which has to use underground wires for the reason that other people have got all the overhead privileges in the town and will not let us get any; consequently we have to go underground. (Laughter.) There is some advantage in starting out in knowing just what you have got to do. You know you have got to spend your money and you are going to take the best care and to get the best work; but the man who has already spent his money, of course naturally objects to taking that all out and starting on the same ground as we have. With regard to the whole question I wish to say a few words upon

it—the results of some patient investigations on my part. I would say that the whole question of underground wires has not been attacked in the right way. The first question is how are you going to distribute the current, and the second is, what effect are your methods going to have on the public. Now it seems to me any system that involves the laying down of enough conductors to supply the business you have in prospect in the next 20 years is a mistake. There is a company in Philadelphia now which has stated that they have spent $250,000 on the copper in the mains in that city, covering a district two miles long and a quarter of a mile wide. They say they expect to put 50,000 lights on those conductors and I guess they may get them in about 20 years. Now if instead of that copper, which by advance in our knowledge may be rendered entirely useless in the next five years, they had put money into conduits it would not have cost them anything like that amount. Now if we start with the idea that you must not have your conductors buried—the actual metal required buried at once—it seems to me that the only thing you can use is a conduit that will allow you to increase by drawing in cables. We know what a conduit will cost. The greatest expense in a conduit is the trench and the repairing of the street afterwards. That would amount to anywhere from 35 to 40 per cent. of the total cost. If you put down a conduit into which you can draw additional cables afterwards you are saving as much as possible of the original expense; not only that, but you are getting rid of the greatest opposition to the underground system—the objection of the citizens to having the streets torn up every time you have a break or want to make a connection. At present all the people in the electric field have the misfortune to be damned by the newspapers for not going underground and doubly damned by the people for tearing up the streets to do it. We reach the point that you must have a drawing-in conduit, and the next thing you must have is the means of distributing the current to every house in the block without digging up the street. That can only be done, it seems to me, by having a small distributing duct running alongside your trunk lines to which you can make your connections the same as you would with a water pipe or gas pipe. The people will make no objection to that. There are such systems; there are dozens of them, and it is not so much a question as to which system you will adopt as that the work should be carefully and honestly done on the start.

The arc light question is one which practically I know little about, but we have heard this morning from Mr. Acheson that the great trouble from the puncturing of the cables evidently arises from the static charge. Now in an arc light circuit, it seems to me that static charge would only arise at the moment of opening and closing the circuit or at the flashing of the machine. In an alternating current, with which I understand Mr. Acheson made his test, the charge is there continuously as it were. Now I have noticed on an arc light circuit a peculiar condition that took place where I was using a couple of ordinary Thomson-Houston lightning arresters on the ends, where every time we opened and closed the circuit we would get a spark across the lightning arrester; and on a night when the machines were working badly I have seen a continuous static spark running across, but I never thought that was a solution of the matter until I heard Dr. Wheeler's paper.

Now I have noticed also a rather curious thing that occurred on our circuits with the alternating current machine. We had three armatures give out without any sign whatever. They tore all to pieces. We examined them as carefully as we could and came to the conclusion that there had been a short circuit in the wire of the armature itself. The men told me that regularly for two or three days before the armatures gave way they saw the sparks on them. Owing to one of those break downs we had to overload a machine one night, and one of the men told me that the machine was sparking. I found a little spark jumping from one of the pole-pieces into the armature, a very bright little spark. I came to the conclusion that it was the charge in the belt. The machine was insulated on a good dry floor. I ran over to the ground detector and I found a slight leak on one of the circuits. I concluded that that was a static charge from the belt. I threw a little of the load off the machine and the spark stopped jumping. I put combs on the belts and we have had no more sparking of that kind. I examined that armature and I found that the mica covering the wires was punched, and that is satisfactory evidence to my mind that the spark went through there continually. Now I have had the same thing occur on the line where there is a constant sparking from opening and closing the main circuit, where the spark would jump through anywhere from five to six inches and finally burn right through the insulation, then we would get grounds and we would find a little hole burned through. Now when the convention met in Pittsburgh last spring, I told them I had a good deal of cable out there on the Monongahela bridge running electric lights. I had in there two .0000 cables, 85 to 90 amperes. Those cables ran with perfect satisfaction save one burn-out occasioned by lightning. It fused the copper wires of the conductor together. A piece of three or four inches was cut out and the cables have run all right since. But a little cable we put in there had a very curious experience. The question was raised whether pulling a lead covered cable into a creosoted box would not cause the lead to decomposed and the proposition was made to cover it with some sticky tar compound. I thought I would improve on that by covering the cable with a braiding and saturating that. I put the cable in and told the men to ground it thoroughly. The first night we ran we punched 17 holes in it. I spliced it up and went ahead and the next night it broke out in three places, and I found that the men came to the conclusion that it was so nicely insulated it did not need to be grounded. We grounded it and that was the end of the trouble. The cable had been ruined however and we took it right out. Now that cable when I examined it in a great many places showed no sign whatever of injury to the cable, but the lead was melted right out and had run away. I supposed that was due to the static charge escaping at that point.

If there are any gentlemen who have any questions to ask about what success we have had I should be glad to answer them. For the arc light side of the question I would call on Mr. Sunny. I should like very much to hear from him now as to what his experience during the last six months has been with the additional light he gained at the last convention.

The President—The chair is compelled to call the discussion back to the main point. A good deal of irrelevant matter has been thrown into this discussion during the last hour. The point about it is this: The subway commission came through a representative before this convention with certain statements. Practically they amount to this—that they are putting down a conduit system, that they haven't a single arc light wire working through that system, but that they hope by the 1st of October or sooner to have several. They elaborated the plan and go on with it, but do not tell us what the conduits cost.

Dr. Wheeler—Pardon me. I do not think that statement is so, that no cost is given. As I understand it the cost is given to people who come and inquire for it in the proper way.

The President—The gentleman will pardon me when I say that the question was asked here on the floor what it cost per mile of conduit and there was not a man on the floor of this convention who could answer it. In the paper itself there is no cost given per mile. It is eliminated at the present time from the discussion. The commission says "examine the way these wires are put in and form your own judgment, and we should like it if you gentlemen would make any suggestion that would help us." Now if there is any gentleman who has any suggestions of that kind let us hear them, let us discuss them. If there is any question to be asked these gentlemen who are laying the conduits, let us get that before us and let us go into the meat of the question and take up the general discussion afterwards.

Dr. Wheeler—I would say that I think there is no question about the fact that putting wires underground is a matter of considerable expense. In reply to the inquiry as to what the expense is Mr. DeCamp says I replied I did not know, and that Mr. Leslie replied he did not know. I replied that Mr. Leslie was the proper man to answer that question, and I think Mr. Leslie said that the proper way to obtain an answer to it was individually to make that inquiry at the office of the company. I do not think it is correct to state that Mr. Leslie and I said we did not know what the cost was.

The President—We are going back to the main question. These suggestions that are made on the floor as to the cost did not bring out the answer. That is not before us; therefore we cannot discuss it.

Mr. F. E. Kinsman—I wish to ask what was the size of his conductors through which Mr. Smith was sending 1,000 volts so successfully?

Mr. T. C. Smith—All the way from .0000 to No. 16 Brown and Sharpe gauge, from the single conductor down to double conductors in the same cable; we even have one conductor, three wires in the cable, No. 18 Brown and Sharpe gauge running very nicely.

Mr. Kinsman—What is the length of the longest cable?

Mr. Smith—We have altogether about fifteen miles in circuit, but it is so cut up we cannot give any straight length. The longest direct length is 2,000 feet without a break. That was cable that was made for the alternating 1,000 volt circuit. The longest single length of cable intended for 2,000 volts runs up to about half a mile.

Mr. Lynch—I would like to ask Dr. Wheeler if the commission have adopted as the form of conduits an iron pipe covered by hydraulic cement?

Dr. Wheeler—They are authorizing the building of that kind of conduit. I do not know whether you can say they have adopted it or not.

Mr. Lynch—Is there any other city where the same kind of conduit is being used?

Dr. Wheeler—Yes, they are using them in Chicago. In Chicago they had a conduit made of creosoted wooden tubes, in which they tried some arc light wire. The arc light wire set fire to the conduit, and they tried to put out the fire with chemical engines. That did not succeed, and they squirted water into it from a steam fire engine, and kept that up for about a week. They found they could not put the fire out apparently. They took that conduit out and replaced it, I understand, with iron tubes laid in hydraulic cement.

Mr. Lynch—How long has the iron conduit been used there?

Dr. Wheeler—I do not know exactly when that was put in.

Mr. B. E. Sunny—I can answer that. The Dorsett conduit was put down about seven years ago. This creosoted conduit has been down only about two years. It did not take a week to put out the fire, but we could not get at it for some days. We stopped up both ends and thought we would smother the fire by depriving it of air. When we were able to get at the creosoted wooden box we took it up and put down iron pipe in its place.

Mr. Lynch—What was the length?

Mr. Sunny—About 105 feet.

Mr. Lynch—And how many ducts?

Mr. Sunny—Fourteen ducts of the creosoted wood, and we put down some sixteen of the iron pipes in its place. I would say that the telephone people have a system of conduits there made of iron pipes. in cement, the same as is being put down by the subway commission in New York now.

Mr. Lynch Dr. Wheeler, has this Johnstone patent that you speak of as being recommended by the subway commission for supplementary leads, been in operation in this country?

Dr. Wheeler—It has been in operation in Philadelphia and Chicago.

Mr. Lynch—But as I understand Mr. DeCamp, there are no electric light wires in it at all?

Mr. DeCamp—It is used now for an incandescent station. Their arc lighting business was abandoned about a year and a half ago

Mr. Lynch - Those are the only two places. This system adopted in New York is in use, 105 feet used for electric lighting in Chicago; the same kind of conduits as now used in New York, wrought iron pipe surrounded by hydraulic cement.

Mr. Sunny—Well, I ought to state in addition that, as to the section of 105 feet, at all the street crossings where we want to cross from one side of the street to the other, it is all iron pipe. Then we have added within the past two or three years a considerable length to the original Dorsett conduit and put it in iron pipe.

Mr. Lynch—What do you use in the form of supplementary ducts in Chicago?

Mr. Sunny—I scarcely know what you mean by that.

Mr. Lynch—In New York they have a main line of conduits running straight through the street. Entrance to the conduits is through the man-holes, which are at every corner.

Mr. Sunny—You understand that in Chicago the sidewalks are all hollow, and the main line of conduit is built along the street the same as in New York. From the man-hole we have what we call laterals running into the four corners of the intersection. We carry our cables in there, and then along under the hollow sidewalk, cutting loops for each subscriber as the service may demand it; so that the question of the distribution of power and light is an exceedingly simple one in Chicago, which is probably the only city that is so fortunately provided.

Mr. DeCamp—Mr. Chairman, I want to correct Mr. Smith and also a wrong impression, perhaps on the part of others. In my statement that there were no light wires underground in the City of Philadelphia that were being successfully operated, I referred only to arc light wires. I think his Honor the mayor is entirely correct, that there has been enough done in the way of operating incandescent or low tension current to justify whatever doubt there may be in regard to it being resolved in favor of success. Mr Smith, in Philadelphia, is using a current of 1,000 volts, and at the February meeting in Pittsburgh I inquired particularly about that, because it was a matter of interest to me at that time, and I learned from Mr. Smith direct that there was a good deal less difficulty in insulating for that 1,000 volts than there was for a constant current of 2,000 volts. Now I went no further. I inspected Mr. Smith's and various other systems, and I have no reason to doubt, and it is confirmed by Mr. Smith now on this floor, when he says that they are using a wire for that current, which was put in there for a current of 200 volts, and are doing it successfully. I do not want any better confirmation than that. That does not come under the head of arc lighting, because of the low potential or the small amount of difficulty in insulating for that particular current.

I disclaim any intention of making any attack on the subway commission of the City of New York. I think they are making a great many mistakes. I have a perfect right to think that, and I have one suggestion to make for them, viz, that they go to work and secure an insulation—which has been suggested from time to time and to-day most forcibly by Dr. Moses—that will stand the currents that are used to-day for general public and commercial purposes. The standard to-day for that kind of work is, say, 3,000 volts. Treat it exactly the same as you would treat a steam boiler that you want to carry 100 pounds pressure; have the initial test made to 150. In securing your insulation for 3,000 volts give it the benefit of fifty per cent. increase. When you have secured that insulation then is the time to take up the question of subway, the question of conduits, the question of distribution. I would like also to make this suggestion: Is there a gentleman on that subway commission, or on the floor of this convention, who is prepared to say that when they accomplish the object I suggest that their whole scheme and system of subways will not be found to be entirely useless. The calculation of eight wires to a duct to-day is based on the insulations of to-day. If it is necessary to double or treble that insulation in order to secure it, it would reduce the capacity of that duct to one half or less. By the time they get through with that insulation perhaps they will find the whole thing useless, and they will have to have some other sort of system. Therefore, I think the time and money spent on the subway conduit is wasted.

Mr. Sunny—I should like to add something to what I said at Pittsburgh relative to the underground experience at Chicago. As you all know the arc light business at Chicago is all done through underground wires. The electric light companies never had any poles or wires in the streets, so that they never have been in the position in which the electric light companies in New York and Philadelphia are to-day. They started out with underground wires; they never had any other method of doing the work, and have had to do the best they could with the underground problem. We have done a great deal of work in that direction; it has been interesting, but it has been awfully expensive. About the latter part of last year all of the smaller companies were organized into the present company, the Chicago Arc Light and Power Co., and a new central station was built, into which all the circuits were carried. The conduit is filled up with wires insulated with Okonite, having an insulation of about 3-32ds. of an inch in diameter. Those wires were not used more than thirty or forty-five days, and were then abandoned because they burned out; but I ought to say in connection with that, that it was not any fault of the Okonite insulation; that company furnished those cables on the express understanding that the conduit was a perfect insulator, and that even a smaller insulation would have been large enough to carry the current of 2,250 or 2,500 volts. It was thought, after those cables burned out, that something to protect the insulation ought to be provided, and lead cables were selected having an insulation of the same size as the Okonite—3-32ds. of an inch. Those cables lasted about sixty days. and in January we had to pull them all out and throw them away, something like forty or fifty miles of them, and then we put in cables covered with lead, having an insulation of 6-32ds. of an inch. This is a paraffine insulation. The cables of 6-32ds. insulation have been in service about seven months. So far we have had four interruptions; that is four grounds have been developed in those cables. There are about 32 circuits carrying about 1,200 lamps. We have had four cases of trouble in those large cables. Of those four cases two have occurred in the Pittsburgh cable, and two in the Western Electric cable. We have been able to get at two of those pieces, one of the Pittsburgh and one of the Western Electric. We find that in one case the burn-out was caused by mechanical injury, and in the other by a discharge between the lead and the copper which burned out the cable. The other two cases we have not been able to get to, and we do not know whether they have been caused by mechanical injury or by the heavy current.

Now, while we do not feel that we have solved the underground problem we feel that the last six months has indicated that we are on the right track, and we are very hopeful that we have succeeded in finding a cable that will carry the current and give us permanently secure service.

With regard to the cost I have made a few figures that are very near correct, based on the experience that we have had. It costs us about $1,500 for putting in one circuit for two miles, one mile out and one mile back. That $1,500 includes the lead cable and the lamps. We are able to pull three cables into one duct of the conduit, and the charge for rental is a thousand dollars per mile per duct, so that each wire has to stand its proportion of the expense, which would be $333 a mile per year. Now it is very hard to tell, I cannot say with any degree of confidence, that those cables are going to last five years. They may last ten or fifteen; perhaps they will not last one year. We know nothing about that. But if they last five years we will have paid in rent $3,330, and the original expense of the cable of $1,500, a total of $4,830, which is $20 per year per lamp. I do not know what it cost you for aerial lines, but I think that you can count on a cost of from $18 to $20 a year per lamp on underground work.

Mr. Perry—I would like to ask Mr. Sunny if he is making any extensions of the Dorsett conduit.

Mr. Sunny—No, sir; we are not.

Mr. Perry—When you extend your conduit system what do you use?

Mr. Sunny—We are using iron pipes for the reason that our extensions are very small, and it is handy and quite inexpensive to put down. But if we were to make any considerable extension we would use Cyprus pump logs.

Mr. Perry—You are not afraid of their getting afire again?

Mr. Sunny—No, I am not afraid of that, because they become soaked with water, and I do not think there would be any danger of burning out.

Mr. Perry—Where you put three wires in a duct do you put positive and negative?

Mr. Sunny—We did put them in indiscriminately last year, but in putting in the new cables we have put the positive wires in one duct and the negative wires in another.

Mr. Perry—Where you cross the street do you use the concrete around your single iron duct?

Mr. Sunny—We do not. I would like to say, in connection with Mr. Acheson's paper, that we were very much interested, as you can readily believe, in finding out why it was those cables burned out. When we selected a 6-32ds. insulation to substitute for a 3-32ds. insulation, we did not know just why we did it; but we had to do something, and we thought if a 3-32ds. would burn out, and 4-32ds, of which we had a little, would not burn out except on rare occasions, that if we took 6-32ds. we would be pretty safe, so we took 6-32ds., and we have had only four cases of trouble. I made some experiments three or four weeks ago, and I am sorry to say that I cannot fully agree with Mr. Acheson in his explanation of why those cables burn out. As I understand, his theory is that where lead cable is used, the dynamic current passing through the copper conductors generates a static current in the lead, and after enough has been stored up in the lead a discharge takes place, which is generally through the insulation puncturing the cable. The experiments that were made were these: We spread out a piece of lead covered cable on one of the floors of the building. This cable was 960 feet long. We connected it to one of the arc circuits, making it a part of the circuit. We connected the lead—nine—which, understand, was perfectly insulated from the earth and from the proper conductor; we connected the leads with a condenser, and then discharged the condenser, and got a spark about 1-64th of an inch long, a spark which evidently would not jump through the finished insulation we have in use. We found, on examining the condition of the circuit on the outside with which this piece of cable was connected, that the insulation was something like a meghom. Then we took this piece of cable off the outside circuit and put it on what you might term an idle circuit, where the insulation may have been about five meghoms. We found that we got no noise and no discharge from the lead. The conclusion that we have reached in the matter is, that if you get your insulation on the outside up to a point above a meghom that there is not any danger of your lead cable; that there is no static electricity generated in the lead; but that if the insulation of your lead cable is low, if it is down to 250,000 ohms, which is practically a ground on one side, you get the thumping of the dynamo trying to reach a ground ahead of the resistance of the lamps on the other side. It seems to us that it is nothing more or less than liquid, practically and simply, without any static electricity to it.

Dr. Wheeler—I would like to ask Mr. DeCamp what he meant by stating, and he stated it very emphatically that the problem is not one of subways but of finding something to put in them, and if he meant that insulation could not be found, as far as he knew, which would answer in the subways, I would like to ask if the experience related by Mr. Sunny does not answer his question?

Mr. DeCamp—No, sir, it does not answer it. I refer entirely to the difficulty of insuring an insulation that will stand the current it is necessary for us to use to carry on the business that is now conducted; that is, a high potential current. I do not consider that that has been done successfully. When I say successfully I mean commercially successfully. Mr. Sunny is very fair in his statement. He tells you that he is not prepared to say that the last seven months' experience is evidence that his last effort is a success. Certainly his former efforts were not successful because he pulled all his wire out and put in new wire. Now do not make any mistake about it, because when you get that insulation, and if you and I live long enough we will probably see it, you will very likely find that all the provisions you have made by these subways are entirely useless for that particular kind of wire.

Dr. Wheeler—But don't you think that in view of the number of grounds they ordinarily have on overhead wires, that an experience of getting only four grounds on a large number of circuits is very satisfactory, especially for a place where this work has been tried for the first time? First work is always poorer than subsequent work.

Mr. DeCamp—I would consider four grounds on an underground cable equal to 400 on an overhead wire, because that is simply a matter of a few moments.

Dr. Wheeler—It depends a good deal on whether you are looking at it in the light of public safety, or in regard to keeping the lights burning.

Mr. DeCamp—That is the only thing that his Honor omitted to state yesterday with his usual clearness. He quoted to you the statistics as to the danger of electric light wires. It is so infinitesimal as compared with that of any other industry, that I do not think it is creditable for us to discuss it, but the question is a very serious one, when you get all your wires underground, whether wherever they do come above ground, the danger is not very greatly increased.

Dr. Wheeler—No, because the length of wires exposed, from which people get shocks, is very much less.

Mr. Acheson—I would like to ask Mr. Sunny what he refers to, when he speaks of the noise that he heard in the cables—the thumping?

Mr. Sunny—I ought to have explained that among the tests that were made after we discharged the current into the condenser and then discharged the condenser, then we connected a telephone into the lead on one side and a ground on the other and listened to the racket made by the Thomson-Houston machine. We got a tremendous racket. When there was practically a ground on one side of the outside circuit we could hear the noise for a distance of fifteen feet, but when we put this piece of cable on the house loop, the noise was practically nothing.

Mr. Acheson—It is quite evident that the difficulty he found in obtaining a spark was due to the want of a charge. You cannot get the discharge until you first have the charge, and the fact of his obtaining no noise was an evidence that there was no charge formed. If there had been a charge formed, you would have heard it through the telephone

Dr. Moses—Will Mr. Sunny please explain to us the data once more, so that we may be able to judge for ourselves, whether there was a charge or not? Just give us the conditions of the experiment. Will you please tell us what the object of the experiment was and what the conditions were under which the experiment was made.

Mr. Sunny—The conditions were simply these: This piece of lead cable 950 feet long, was strung out on the floor. The floor was perfectly dry, so that the lead was well insulated. We connected the lead to one side of the condenser. The other side of the condenser was connected to one of the copper conductors—perhaps I omitted saying that in the first place,—then we discharged the condenser and we got this spark of about 1-64th of an inch.

Dr. Moses—It seems to me from the conditions of the experiment that Mr. Sunny had only put together a rather elongated Leyden jar. The superficial area of the lead envelop was the equivalent of the exterior coping of the jar, and as he premised by saying that it was laid out on a dry floor, it shows that it was very well insulated and consequently could not fully discharge itself, or reaccumulate and charge itself, and that, thereafter he only got evidence from the electricity that had gathered on the exterior of the Leyden jar.

Mr. Weeks - Mr. Sunny stated to the convention, if I understood him correctly, that the cables that were first put in have all been withdrawn. Can you, Mr. Sunny, state to the convention the loss to your company represented by that experience—the loss of those cables, and the drawing-in of the new?

Mr. Sunny—I can only state the loss approximately. It is very difficult to arrive at any definite conclusion with regard to that, because it not only lost us the cables themselves, but it lost us the growth of the business we were sure to have; it lost us a reputation for service, and we lost in so many indirect ways that it is very hard to determine just how we came out. I should say, however, that the substitution of the cables, changing them three times cost us about $50,000

Mr. Weeks—How long had those original cables been in before they began to fail you?

Mr. Sunny—They were practically new. They were not in long enough to be at all acted upon by any excess of moisture underground, and I think it was purely a case of thin insulation. They had not been in more than four or five days, I think. I was not connected with the company at that time, so I cannot answer that question positively.

Mr. Weeks—I would like also, Mr. Sunny, if you will kindly do so, to have you state to the convention what the insulation of your circuit is by your daily tests. When I visited your station last, I found that you were making daily tests of the insulations of your circuits, and I found that about eighty per cent. of your circuits, on the occasion of my last visit were disabled, through the fact that their insulation was so low that you could not run on them. I think, if I remember correctly, some of them ran down to below 1,000 ohms.

Mr. Sunny—I would like to ask Mr. Weeks when he secured this information—about how long ago.

Mr. Weeks—About six months ago, when I called at your office.

Mr. Sunny—I can answer that question better, I think by quoting a remark that Mr. Haskins, the city inspector of the electric light, made a few weeks ago. We send him a report every Monday morning, showing the insulation tests of our circuits, taken the day before—Sunday. He has kept those reports, and he says he sat down and figured them up for several months, and that the average insulations of all of our circuits was 550,000 ohms; that those tests were taken on dry days, wet days and in all kinds of weather. The tests was invariably made Sunday morning, at about the same time, without regard to the condition of the weather. His figures were based, therefore, on an average running all the way through, and I think that it was a very fair average. Our circuits now measure a meghom in fully 95% of the tests. I do not know how much higher they measure because that is the capacity of the galvanometer used for that purpose. If they are a meghom we are satisfied. If they are below that, we go for them. We have still some Okonite and Kerite and

Bitite and other ite wires in service, and the low insulation comes in, in those wires becoming soaked with water and becoming crossed with some metal or some stone sidewalks.

Mr. Eustis—Is that insulation for a double circuit?

Mr. Sunny—That insulation is for a double circuit. There are thirty-two circuits; none are less than two miles and some of them are five.

Mr. Perry—Has there been any deterioration from the time you first placed these cables in your box to the present time? Have the cables individually, each one, held up to full standard, or has there been some deterioration?

Mr. Sunny—No, sir; there has been no change in those cables, with the exception of the four cases of trouble I have referred to. The insulation holds up first-class. With regard to grounds coming in on these cables, we do not look upon that as half so serious a thing as Mr. DeCamp does. When your circuit is started up, it measures a meghom or more. We do not know that the circuit is grounded until three or four hours before the next run or the next morning, so that that ground has not interfered with the service at all. Before it is time for that circuit to start up again, we have cut in a new section of cable to take the place of the defective one and are ready to start up without any loss of service. The expense of a case of trouble is the labor of pulling out a piece of cable and putting it back again. Under the manufacturer's guarantee, we get a new piece of cable to take the place of the defective one. That guarantee is three years.

Mr. Perry—At the end of that time you will pull them out at your own expense?

Mr. Sunny—I hope not.

Mr. Perry—I must say that, notwithstanding the fact that Chicago has been laboring so successfully with this matter for seven years, and notwithstanding the fact that they have, for the last seven months been operating beautifully, this thing is not ripe enough for me to pick.

Mr. Law—Mr. Sunny seems to think an underground wire is not a serious matter. We, in Philadelphia, have found it to be a very serious matter. I think when you have fifty or sixty lights burning, a ground has been developed, which may be in a section of wire, one, two, or three miles long. It is a difficult matter to look at that ground in your length of wire and get it out. You perhaps start up that night with a ground on your line. About eight o'clock at night, perhaps, the telephone rings and you are informed that the lights are all out on No. 5 circuit. The horse is hitched up and you go driving out on the street and you hunt for some time. You find the extremes of your ground, shut down your station and run a new line overhead between the lamps in order to make the connection. Your lights have been out all that time, perhaps one hour, two hours, or three hours, as the case may be. It depends altogether on how much time it takes you to put the wire up between the two lamps. Now I call that a pretty serious matter to have a whole circuit of lights out. Perhaps the whole circuit might not be out but a few minutes, but the lights between the two grounds are out all the time you are trying to get the circuit re-established. Now that was a matter that has happened to us, not once, but several times. I have had lights out on one circuit varying in number from fifteen to fifty-three lights, out for several hours during the evening; and the only way to fix those lights was simply to run an air line between the last two lamps. Fortunately the distance was not very great, and so we could do it very comfortably. Another section of cable two miles in length was grounded. In order to find that I had to make three cuts on that length of cable; I located the trouble in one length of 730 feet and procured a new cable. I pulled the cable out and found the burn perhaps 250 feet from the end, but in finding that, I also found that the lead on the cable was so honeycombed that it would be perfect folly to put it back. Therefore, I drew out the whole length of cable and put in a new one. In drawing that out, there was perhaps fifty pounds of sulphate of lead that dropped in the man-hole as we drew it out, showing the immense ravage that had been occasioned there. That cable had been underground about thirteen months.

Mr. Sunny—I do not wish to be understood as belittling the importance of keeping away from grounds or keeping them cleared up. Before we start out with our circuits, measuring the meghom, we cannot tell if a ground is developed on one side of that circuit unless the lights are reported out. I had reference more particularly to the four grounds in those new cables. In no one of the four instances did we lose any service on account of those grounds. It does not take more than an hour to change a ground on any one of our circuits, and when we were having so much trouble, we would perhaps have eight or ten cases of grounds in the morning, and we would generally have it all cleared up by three o'clock in the afternoon. We have a very good system in respect to that, and so far as losing service is concerned on account of those grounds, we do not look upon it as a very serious thing.

Mr. Weeks—The question of the loss of service is not the most important matter in connection with the ground. It is tolerably certain to occur however. You will lose your service, but there are other contingencies that may be very much more serious, for instance fire caused by a second ground or that ground, or injury to individuals. Our average insulation has been very much better than Mr. Sunny's in Chicago; but recently when we had a ground on one of our circuits, it so happened that a citizen of the city made a second ground. The result is a $10,000 damage suit.

Mr. Smith—I would like to ask Mr. Law if the second ground which cut his lights out occurred on the underground cable or on one of the aerial lines?

Mr. Law—It occurred on the underground cable. One case was at three o'clock in the morning, and the other, if I remember right, about nine o'clock at night. Our lamps are set on iron posts with a wooden block on the top to support the lamp. Under that wooden block is a terminal box in which that lead cable is inserted to protect the insulations of the lead cable. From that, we carry out Okonite wire to the lamp. A short circuit occurred in the terminal box between the wire and the lead, or between the wire and the case of the terminal box. In both cases, it burned off the wires—not only burned off the wires, but burned off the wooden blocks on the top of the poles, in one case dropping the wires and everything into the street.

Mr. DeCamp—I would state for Mr. Smith's information, that just before leaving home, I noted on the daily record of tests on the line Mr. Law refers to, which is about one-third aerial line, and two-thirds underground, that there were seven grounds reported during the month of August, up to the time I left, which was last Monday. They were all on the underground part of the circuits. There were no grounds on the aerial part of the lines.

The President—Gentlemen, the chair has given the widest latitude to this discussion, realizing that, not only the gentlemen present, but the people they represent, are vitally interested in this question, and not only they, but the public at large also, and the discussion this afternoon has been profitable in this respect. It has developed the fact, that while in Chicago and in New York city and in Pittsburgh, Philadelphia and other cities, they have claimed that there has been no progress and no efforts made by the electric light companies to solve this question, yet it has been demonstrated that these companies, individually, working alone from their different standpoints, have each taken up this question, and have attempted to solve it for themselves. They have not only done that, but they have communicated one with another, and obtained the best information they could.

When we first started to put up arc light circuits, we had a wire that every one now condemns. We forced the manufacturers into making these wires we are now using, when we showed them they had to do it, and we will go on and show our vital interest in this subject, by the appointment of these committees provided for in the resolution to-day.

This discussion has developed the fact that the gentlemen here in New York are going ahead, with the best knowledge and the best intelligence they have at their command, and they ask us as a representative body of men to start in and aid them as a body. We have never done that hitherto, but you gentlemen, in your resolution to-day, have provided for the continuance of the committee on the insulation of plant, and you have a vast amount of practical knowledge, as reported by Dr. Moses, to be collated and to be given to these manufacturers, and not only improve the condition of insulation, but improvement of the wire itself. You have gone further; you have provided for a committee of five, which shall collect data with respect to insulation from time to time, and report at the next convention six months hence what has actually been done, what are the practical results, what has been the cost, what it is going to cost, so far as they can find out. I say we are in the right direction. That leads up to another thing in my mind. It shows that you will need a permanent office somewhere where you can get this information, where it can be furnished, not only to the members of the association, but to the outside public and to municipalities and others who are clamoring for every one to go underground. I know if we could prolong this discussion, we could get more valuable information; but it cannot be done with the limited time at our disposal, and these New York gentlemen are so exceedingly kind in their attentions that they practically take up half the time of the convention. Of course we are very thankful to them. At the same time, that is the status of the case, and I am compelled to close the discussion.

The chair will name the committee on underground wire to-morrow morning. I will make one or two announcements. The first is that I shall appoint Dr. Liebig, of Baltimore, in place of Professor Thomson, on the committee on insulation and installation of plants. I want to say, gentlemen just here, that instead of members thinking it is no honor to be put on a committee of this kind, as might be inferred from the action of the committee hitherto, in simply reporting progress, that I should regard this as one of the highest honors that can be conferred on any member, and at the next meeting we will demand a report in writing from the committee, or know why they do not furnish it. They have reciprocal duties towards the association and if they do not intend to perform them, I wish they would so state when they are appointed.

Mr. T. Carpenter Smith—I believe an explanation is always in order, and I wish to make an explanation to the members

of the convention. In a letter which I wrote to a gentleman in this city, which was afterwards read to the board of electrical control, I made the statement that the inspector of lights in Chicago had shown a discharge from a magnet as an instance of an alternating current. I made that statement on the authority of a newspaper report of a lecture that he delivered. I received a letter from Mr. Haskins subsequently, imploring me not to put him down as an electrical idiot. I expected to meet him at this convention, when it was my intention to make a personal apology to him. But he is not here, and I know of no other way than to make my apology in the presence of this convention. I withdraw the statement then in the presence of this association.

Mr. A. F. Mason, chairman of the committee on revision of the constitution, presented as a report the following amended constitution:—The report was signed by A. F. Mason, G. M. Phelps, Geo. F. Porter, and Henry D. Stanley, committee.

(The amendments made by the convention to the draft of the constitution reported by the committee are incorporated in the text below, the corresponding parts of the committee's report being given in brackets.)

CONSTITUTION.

Article 1—*Name.*

The name of this association shall be the National Electric Light Association [The Electric Association].

Article 2—*Membership.*

SECTION 1.—Any individual or member of a company or firm operating an electric light, power, heat or welding station for public or commercial purposes; and any individual or member of a company or firm manufacturing electric supplies or apparatus, may become a member of this association by the payment to the treasurer of one year's dues.

SEC. 2.—Electricians, electrical engineers, and those whose profession or business is directly related to electrical interests or to the commercial application of electricity, may, upon the recommendation of the executive committee and a two-thirds vote of the association, become members thereof, by the payment to the treasurer of one year's dues.

SEC. 3.—Upon the unanimous recommendation of the executive committee and the approval of a two-thirds vote of the association, persons may be made honorary members of the association, with all the privileges of membership, except the right to vote.

Article 3—*Officers.*

SECTION 1.—The officers of the association shall be a president, two vice-presidents, a treasurer and a secretary, and an executive committee, to consist of the above-named officers, *ex officio*, and nine other members.

SEC. 2.—The president and vice-presidents shall be elected by ballot to serve from the close of the annual meeting at which they are elected until the close of the next annual meeting.

SEC. 3.—No person shall be eligible for the office of president or vice-president for more than two successive terms, but this shall not be construed to forbid the election to the office of president of one who has served as vice-president.

SEC. 4.—The secretary and treasurer, who may be one and the same person, shall be nominated by the president, subject to confirmation by the executive committee. The salary of the secretary shall be fixed by the executive committee.

SEC. 5.—The executive committee shall be chosen by ballot at each meeting, either annual, semi-annual or special, and hold office from the close of the meeting at which they are elected until the end of the meeting at which their successors are chosen.

SEC. 6.—The treasurer, secretary and executive committee shall make written reports at each meeting, which reports, upon their acceptance, shall be spread upon the records of the association.

SEC. 7.—The executive committee shall be the governing body of the association. They shall meet at the call of their chairman, from time to time, and shall report upon applications for membership, shall gather and prepare information upon topics of interest, and shall arrange for their discussion at the several meetings of the association. Five members of the committee shall constitute a quorum.

Article 4.—*Meetings.*

The annual meeting of this association shall be held in February, and a semi-annual meeting may be held in August of each year, at such places as the association shall determine, and on such dates as may be determined by the executive committee.

Article 5.—*Dues.*

The annual dues shall be $20, payable in advance, and shall cover the calendar year.

Article 6.—*Ballot.*

On any question before the association a ballot may be demanded by ten of the members present [one-fourth of the members present].

Article 7.—*Amendments.*

SECTION 1.—Amendments to the constitution shall be presented in writing, and referred to a committee to be appointed by the chairman before being acted upon by the association; a two-thirds vote of those present shall be necessary to their adoption.

SEC. 2.—No amendment shall be voted upon on the day of its first presentation.

The constitution as above printed was adopted, and the committee was discharged with the thanks of the association.

The convention then adjourned until the following day at 10 A. M.

THIRD DAY'S PROCEEDINGS.—FRIDAY MORNING'S SESSION.

The President—We will open our proceedings this morning by taking up the reports of the various committees. In the absence of the secretary I will state in a few words the report of the transportation committee. They made every effort to obtain a reduced rate to this meeting but they failed in their efforts although various promises had been made to them. They now have a letter signed by Mr. Daniels promising that if the next meeting shall be held west of Pittsburgh the railroad association will give a one and a half rate for the round trip. That may be considered as the report of the committee on transportation.

On motion, duly voted, the president then appointed as a transportation committee for the next meeting George F. Porter, of Philadelphia, chairman, Morris W. Mead, of Pittsburgh and F. E. Degenhardt, of Chicago.

The committee on the New England Insurance Exchange, Mr. Frank Ridlon, chairman, reported as follows:—

REPORT ON THE NEW ENGLAND ELECTRIC EXCHANGE.

Mr. President and Members of the National Electric Light Association:—

I beg to submit to you the report regarding the New England Electric Exchange, as requested by the chairman of your committee, at the last meeting of that committee. This subject was first thought of and talked about at the electric light convention held in Baltimore, in February, 1886, and has several times been referred to since; but only in March of the present year did it assume any business form. On the date referred to, the Boston Electric Club sent out a notice asking the various electric light companies or their representatives in the New England states, to meet together at the rooms of the Boston Electric Club, that we might discuss the relations between us and the New England Insurance Exchange, representing the insurance interest of the New England states. Added discussion of the difficulties then existing, or that might exist, between the electric light companies and the telephone and telegraph companies—these matters having been fully discussed in the afternoon and evening sessions—led to the formation of the New England Electric Exchange, which consists of a president, vice-president, and three directors. Since the first meeting, we have held one regular meeting of the exchange, on a date provided for in our constitution, and the president, secretary and directors have met from time to time, formulated a constitution and by-laws for governing the exchange, copies of which I submit, and appointed examining boards for the purpose of examining applicants for licenses; and have now five boards, consisting of three examiners each, to attend to that part of the business. These examinations have been faithfully carried out, and some 50 applicants have passed the examination required, and have, or are about to receive their licenses for such a class of work as they were found competent to do. We have been ably aided by those who we may now term our friends, the officers and members of the New England Insurance Exchange. They first encouraged us by offering a reduction in insurance where buildings were exclusively lit by electricity, and also where power was furnished from the same source. Lately they have issued a notice, stating that on and after the first of October, they would cease to issue permits for insuring buildings where electric lights were in operation, unless the party operating the plants should hold a license from the New England Electric Exchange. In addition to this, they are about to carry into effect a personal notice to all central stations, the same to be carried out in a personal interview between their representative, Mr. Brophy, and the party in charge of the central station, wherever the same may be located in the New England states. I believe that the success of this organization, depends on the thoroughness with which the business as set forth, shall be carried out; and that part having been accomplished in a thorough and satisfactory manner, it will not only advance the interests of electric light and electric power as a whole, but will free us from those petty annoyances and uncharitable remarks which are often given to different systems; being almost wholly brought about by want of proper care in constructing and maintaining plants. This may sometimes be due to carelessness, but more often it is a case of want of knowledge by the operator; who would gladly seek that knowledge, had he any means of obtaining it. As that knowledge has become a necessity, it would seem to be a duty for us to establish schools and places of instruction

in our large cities, where intelligent workmen may seek and obtain the information they wish. This can easily be done in our electric clubs where we have the books and periodicals, with everything relating to the rapid advance of the business. Also able instructors in our members, who would be perfectly willing to devote one or two evenings in a week, during the coming winter, to the instruction of those who may wish to increase their knowledge of the business, to which they intend to devote their energies. These schools added to the scientific lectures and reading of papers on electrical subjects, which were so much credit to their writers during the past winter, will very largely aid in bringing forward our young men, and give them that practical experience, which joined to the technical knowledge they may have obtained, would bring about that degree of perfection which would promote confidence with the insurance people as to the ability of those employed in electric light stations ; and last but not least, satisfy the capitalist that the money he has risked in carrying out electrical enterprises, will be judiciously and intelligently expended. FRANK RIDLON.

On motion, the report was received and ordered filed, and the committee continued, to report any further information they may get on the subject at the next meeting of the association.

The President--The chair announces as the committee, proposed by Mr. Lynch yesterday, to obtain practical information in regard to underground conductors, E. T. Lynch, Jr., chairman, C. H. Barney, F. B. Crocker, C. H. Davis, and Walter C. Kerr.

Mr. Steuart—Yesterday at the close of the discussion upon underground wires and underground conduits, there seemed to be an absence of point to the action of the association, and some of the members considered that it might be well to put the matter into some definite shape in order that the public might know what we did think upon this subject; I have, therefore, drafted the following resolution and would offer it :
